Disassembly: Install Tool J-5472-25 on inner shaft and insert the two short capscrews through tool and inner shaft, then install the two nuts to hold tool in position. Insert Tool J-5472-5 between inner surfaces of control arms adjacent to inner shaft holes Thread a 3/8" x 2½" capscrew into end of inner shaft and install the complete assembly in an arbor press so one end of inner shaft rests on Tool J-5472-3. Press on capscrew in end of inner shaft until Tool J-5472-25 has pushed shell of bushing to a flush position. Invert control arm in press and put capscrew in other end of shaft, then press second bushing to a flush position. Remove control arm from press and knock the bushings out the rest of the way with a hammer and blunt chisel.

Reassembly: Insert one end of inner shaft in one arm of lower control arm, then install opposite end in other arm. Place Tool J-5472-5 in position between ends of control arm. Start a rubber bushing in each hole at end of control arm, then place Tool J-5472-2 in position on each bushing, force bushing into place using an arbor press, until shoulder on outer sleeve of bushing is seat-

CONTINUED ON NEXT PAGE

1954-60 STUDEBAKER & PACKARD (Continued)

ed in control arm. Install bushing cap, washer, lockwasher, and capscrews. *(NOTE* - Tighten these capscrews to 32-37 ft. lbs. after control arm has been installed on car and weight of car is on springs).

Installation: Place one side of outer end of control arm over one end of outer pin and install opposite side of control arm on outer pin. With marked side of inner shaft up, align holes in inner shaft and holes in frame bracket, and install retaining bolts. washers, and nuts. *(NOTE - Outer ends of upper control arm must be spread .015" before installing outer pin and threaded bushings. Determine this dimension by adjusting a pair of calipers to fit over outer end of control arm adjacent to bushing holes, with a .015" feeler gauge inserter between outside surface of control arm and one prong of calipers).* Install spreader Tool J-2044 and spread ends of control arm to setting of caliper. Start bushings on ends of outer pin, then center end of kingpin in control arm. With spreader still in place, start bushings and tighten to 170 ft. lbs. minimum. Remove spreader and install wheel assembly. Check and adjust front end alignment.

STEERING KNUCKLE: Removal - Raise car and support it at outer end of lower control arm. Remove wheel, hub, and drum assembly. Remove brake backing plate assembly from steering knuckle flange without disconnecting brake hose and suspend the assembly in an out of way place (do not allow assembly to hang on hose). Disconnect tie rod from steering knuckle arm. Remove cotter pin and kingpin retaining nut, then using a lead mallet, drive kingpin upward out of lower support. Remove upper control arm outer pin bushings and remove kingpin and steering knuckle assembly from outer pin.

Steering Knuckle Bushing & Bearing Replacement - Invert steering knuckle and place Adapter J-1294-9 on inner end of bushing, then insert Pilot J-1294-4 in bearing end of knuckle and press bushing out of knuckle with Arbor J-1294-A and an arbor press. To remove needle bearing, turn knuckle over and place Adapter 1294-9 on inner end of bearing and place Pilot J-1294-4 in bushing end. Use Arbor J-1294-A and press needle bearing out of knuckle. *NOTE - Bearing rollers (41) may fall out when kingpin removed.* To install bushing, place Pilot J-1294-6 over arbor with wide shoulder of pilot against shoulder of arbor. Insert Pilot J-1294-4 in bearing end of knuckle and press bushing in until Pilot J-1294-6 stops against knuckle. *NOTE - Bushing will be exposed about 1/16" above knuckle.* Remove Arbor J-1294-A, reverse Pilot J-1294-6, and press bushing in until pilot stops against knuckle. To install needle bearing in knuckle, place Pilot J-1294-4 on Arbor J-1294-A so that wide shoulder of pilot is against shoulder of arbor. Place bearing on Pilot J-1294-4 so that lettered end of bearing is against shoulder of pilot, then insert Pilot J-1294-6 in bushing bore. Insert the arbor in bearing end of knuckle and press bearing in until Pilot J-1294-4 stops against knuckle.

NOTE - Bearing will be processed in knuckle, leaving spacer from rack gasket.

Steering Knuckle Endplay Adjustment - Place kingpin in a vise and install steering knuckle on kingpin without the cork gasket (normally installed in bottom of knuckle). Install the thrust bearing and shims on kingpin, then insert a .003-.006" feeler gauge between shoulder of kingpin and steering knuckle. Place a straightedge across top surface of thrust bearing and lower shoulder of kingpin and press down on thrust bearing. If surface of the thrust bearing is not flush with shoulder of kingpin, remove or add shims as required.

Installation: Install upper control arm outer pin *(see "Upper Control Arm" above).* Place thrust bearing, shim, and steering knuckle on kingpin, making sure that shim is located between thrust bearing and steering knuckle. Install Woodruff key in kingpin, then start lower end of kingpin in through support far enough to allow installation of the kingpin through the support. Install cotter pin. Install brake backing plate assembly and wheel and drum assembly. Check and adjust front end alignment, then tighten kingpin upper retaining nut.

2-Wheel Dr. Sed. D l. (Exc. 6-226) 1954-55

►CHANGES, CAUTIONS, CORRECTIONS

►**SPRING MOUNTING PRODUCTION CHANGE (4-63 & 6-63):** Effective Serial No. 65974 (4-63) and Serial No. 12098 (6-63) front spring clip plate changed. Parallel plate and two spring clip plates were added. Clip plates fit over ends of "U" bolts and are held in place by the downward projecting edges of parallel plate preventing side movement of spring and any change in camber.

►**REPLACEMENT SPRING CAUTION (4-63 & 6-63):** Manufacturer recommends that whenever front spring replacement required, special **Heavy Duty Spring** be installed on assumption that car is subjected to overloads or operated on rough roads. When these springs installed, other parts should also be installed as follows:

Replacement Spring Parts

Heavy Duty (Export) Front Spring	No. 646855
Spring Clip (2 required)	No. 646813
Spring Bumper (2 required)	No. 645763
Spring Clip Plate (2 required)	No. 641020
Front Shock Absorber	See Note

►**TOE-IN CAUTIONS TO PREVENT UNDUE TIRE WEAR:** Excessive tire wear may be caused by incorrect toe-in due to following causes:

Bent Tie-Rods—May be caused by tie rods contacting rails of "free-wheel type" lift and weight of wheels hanging on tie rods in this position.

CAUTION—Wheels should be blocked up when car raised on this type lift.

Incorrect Toe-In Adjustment Procedure—Toe-in changes with load and must be set exactly as specified under Toe-in below.

►**KNUCKLE SUPPORT INSTALLATION CAUTION:** on right & left side similar in appearance but must **not be interchanged** (results in wrong camber causing unstable steering). These parts marked for identification as follows:

Left Knuckle Support—Has part number—641026 (early cars) or letter "L" stamped on front face at center (later cars).

Right Knuckle Support—Has part number—641027 (early cars) or letter "R" stamped on front face at center (later cars).

DESCRIPTION: Planadyne independent suspension with transverse spring serving as lower control arm (spring is "Dow" type with second leaf wrapped around spring eye in main leaf for safety). Short upper control arm is mounted at frame end on rubber bushings (movement of arm on frame bracket shaft permitted by flexing of rubber bushings). Direct acting type shock absorber is linked to spring pivot pin (lower end) and special mounting stud at midpoint of upper control arm (upper end).

CHECKING & ADJUSTMENT: Check front wheel bearing adjustment, tire inflation pressure, steering gear adjustment, shock absorber action, and steering linkage for correct adjustment and freedom of movement first, then check front suspension system as follows:

Tire Inflation: Check and inflate each size tire as follows:
(6.00x15 & 6.50x15)—24 lbs. frt., 28 lbs. rear.
(6.70-15)—20 lbs. front, 24 lbs. rear.

Kingpin Inclination: 5° crosswise.

Caster: 1°. No adjustment (determined by design of front suspension units—correct by replacing necessary parts).

Camber: 1¼-1¾° (4-63, 6-63), 1° (Others). Controlled by shims under each control arm mounting bracket.

►*CAUTION*—Number and thickness of shims under both brackets on same side of car must be equal.

To Adjust—Loosen upper control arm frame bracket mounting screws, remove shims from between bracket and frame (to decrease camber), add shims (to increase camber) **equally at each bracket.** Shims are furnished in thicknesses of .060" and .120" and are slotted to facilitate adjustment (bolts need not be completely removed).

Toe-In: 1/16-1/8" at curb weight (car ready for road with full tank of fuel and spare tire, but without load).

►*CAUTION—Toe-in varies slightly with load and should be checked and adjusted exactly as follows:*

To Check Toe-In: Jack up front wheels, chalk center of tread over entire circumference of both front tires, use pencil to scribe a line at exact center of tread over entire circumference of tires (hold pencil on steady rest while rotating tire). Turn wheels to straight ahead position with steering gear on high midpoint of cam and steering wheel spoke parallel to windshield, lower car so that weight rests on wheels and load or weight down the front end of the car so that the **front spring main leaf is flat** (measure with straightedge below leaf). Roll car forward and backward to allow all parts to assume natural position. **Check distance between marks on tires at front and rear of wheels and adjust to ZERO TOE-IN** (equal distances at front and rear) under these conditions. **NOTE**—With toe-in set at ZERO under above loading conditions, toe-in will be 1/16" to 1/8" when load removed (dependent on arch of front spring).

To Adjust Toe-In: Loosen clamps on adjusting sleeve on each tie rod and turn adjusting sleeves on **both tie rods equally** when setting toe-in.

SPRINGS: ***CAUTION—See "Replacement Spring Caution" above for recommended replacement spring and other changes necessary when this spring installed.***

Standard Spring—"Dow" type with rubber inserts in forged cups at ends of spring leaves (spring movement flexes these rubber inserts).

Heavy Duty (Export) Springs—Not "Dow" type (no rubber inserts) but spring assembled with graphited compound between spring leaves. Both first and second leaves are wrapped around spring eyes for greater safety, and four additional clips are used to distribute rebound stress of main leaf throughout spring. **NOTE**—This spring is recommended as replacement for standard spring above.

SUSPENSION ASSEMBLY: When disassembling suspension system for renewal of parts, assemble as follows:

Upper Support Arm & Knuckle Support: Upper support arm is mounted on rubber bushings at inner (frame) end and on pivot bolt threaded through eyes in arm and in bushing in knuckle support at outer end.

Knuckle Support & Spring Pivot Bolt: When installing support on car, hold support centered on spring eye while installing pivot bolt.

BUICK AIR-POISE SUSPENSION

Buick (1958)

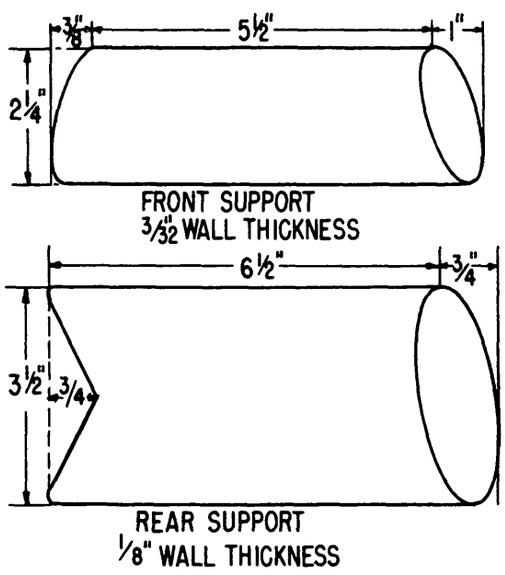
►CHANGES, CAUTIONS, CORRECTIONS

►*SERVICE CAUTIONS:* Before working under the car, jacking it up, or raising it on a hoist, the following precautions must be taken to prevent personal injury or damage to the car.

Raising Car (On a Jack) Before raising car on a jack, pull out the manual lift knob located below instrument panel to right of center heater air outlet, to place car in the full rebound position. Leave knob in the out position while car is on jack.

Raising Car (On a Hoist) - Place car in full rebound position by pulling out on the manual lift knob. See "Raising Car (On a Jack)" above. *CAUTION - While car is on a lift which supports front of car by front spring seats, DO NOT completely deflate or inflate Air-Poise system by any such operation as opening air lines to permit air to escape or running the engine to inflate the system.*

Working Under The Car - Always place jack stands under an air ride car before using a creeper as a precaution in case air should be exhausted from system.



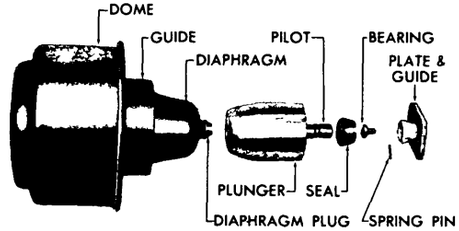
►*TOWING THE CAR:* To prevent bumper from striking the ground while car is being towed (whether Air-Poise system is functioning or not), it will be necessary to block up end of car which remains on the ground as follows: Fabricate blocks (see illustration for dimensions) using metal tubing of 2¼" O.D. and wall thickness of 3/32" (Front) or 3½" O.D. and wall thickness of 1/8" (Rear). Install blocks as follows: **Front End** - Raise car to full rebound position and place a block over lower compression bumper and against bumper contact surface on frame. Repeat on other side of car. **Rear End** - Raise car to full rebound position and place a block over compression bumper on lower side of frame and engage "V" notch on other end of block with top of axle housing. Repeat on other side of car. *NOTE* - Weight of car on blocks will hold them in place.

Towing Procedure - Attach lift chains under bumper face plate and up over bumper back bars *(CAUTION* - Use hard wood blocks between lift chains and plate). Do not tow car at speeds in excess of 20 MPH. *CAUTION - Air-Poise system MUST NOT be in Manual Override position with towing blocks installed (car weight must be on blocks to hold them in place).*

►*AIR TANK DRAIN COCK CLOSING CAUTION:* Damage to valve will occur if valve is closed and tightened more than finger tight (1 ft. lb. maximum).

►*CROSS FLOW "TEE" & RELIEF VALVE LEAK CORRECTION CAUTION:* Do not resolder tubing on cross flow "tee" and relief valve (located at bottom of manual override valve) to correct leakage. Damage to nylon check ball in "tee" fitting and rubber seated disc in relief valve will result. Correct leakage by replacing with later type "tee", Part No. 1179722, or relief valve, Part No. 1185257.

►*FRONT HEIGHT CONTROL VALVE LEVER POSITION CHANGING IN SERVICE CORRECTION:* This condition may be due to lever being assembled improperly on front stabilizer bar. Make sure lever is installed with "bow" pointing toward rear of car. If installed toward front, lever may strike bottom of radiator when front suspension is in rebound position.



BUICK TOWING BLOCKS

►*MANUAL OVERRIDE LEVER LOOSENESS CORRECTION:* If the adjusting lever-to-cam setscrew on manual valve is loose due to stripped threads caused by overtightening, insert a 10-32 nut between lever and shaft (file nut as necessary to allow it to be inserted), then insert setscrew through lever and screw into nut.

►*HIGH PRESSURE HOSE FREEZING CORRECTION (WHERE CAR IS OPERATING IN TEMPERATURES BELOW 32°F):* Every 1000 to 2000 miles, open drain cock on reservoir tank and completely exhaust air supply, then tighten drain cock. Remove Schrader valve core from fitting at top of tank and pour ½ pint of METHANOL anti-freeze into tank. *(CAUTION - Do not use a permanent type anti-freeze as this would cause compressor failure).* Install valve core and run engine to bring air pressure up to normal.

DESCRIPTION: Air springs, consisting of an air chamber and a rubber diaphragm assembly attached to the frame and a piston assembly attached to the lower control arm (front), axle housing (rear), replace the conventional coil springs. Normal riding height is maintained automatically by air pressure controlled by two height control valves (rear), one control valve (front). A manually operated lift control valve located on frame left side rail is controlled by a cable and knob below instrument panel to right of car centerline. This valve, when actuated, provides air to all four springs if conditions require that the car body be raised above normal height. Basic components of the system operate as follows:

Air Compr ss r: This is a single stage, two cylinder reciprocating compressor rated at 5 cu. ft. of air per minute. The compressor shaft is splined to the power steering pump rotor and both units are mounted together. Oil supply for the compressor lubrication is obtained from power steering pump reservoir.

BUICK REAR AIR SPRING ASSEMBLY

High Pressure Reserve Air Tank: This tank is mounted forward of the front crossmember between the two side rails and is used to maintain a reserve supply of high pressure air and to trap moisture and oil in the system. A Schrader type valve on the tank permits filling the tank with air from an outside source. A drain valve on lower left side of tank is provided to drain any accumulation of water and oil.

Manual Override Valve (Car Lift): Located on frame left side rail and operated by a control cable and knob on instrument panel. By pulling out on instrument panel knob, the body can be raised above normal height to a maximum allowed by the rebound bumpers at front and rear. Regulator valves are also included in the manual valve to control air pressure in the system.

Rear Height Control Valv s: There are two rear height control valves mounted on the frame (one at each side) and actuated by linkage connected to rear axle housing. These valves act not only to control height of rear of car but also to maintain proper height of right and left side of car to maintain it in a level position.

Front Height Control Valve: The single front control valve is mounted on the number one crossmember and is actuated by linkage connected to the front stabilizer bar. Its function is to increase or decrease air pressure in the front springs to compensate for differences in car loading to maintain proper car height. Rotation of the front stabilizer bar operates the linkage to actuate the height control valve.

Cross Flow Control Tee: This tee is inserted in air supply line between air springs and front height control valve and is attached to the front control valve. Two check balls and metered orfices allow a restricted flow of air between the two front air springs to maintain equal pressure and not allow a free flow of air when cornering.

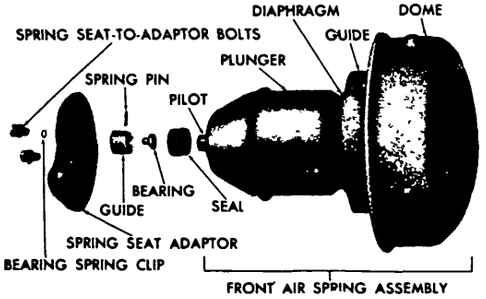
Air Springs: Each unit consists of a metal air dome and a rubber diaphragm assembly attached to the frame, and a piston or plunger assembly attached to lower control arms in the front and the axle housing in the rear. Pressure in the air springs is controlled automatically by height control valves to compensate for differences in car loading.

LUBRICATION: Air Compr ss r - Check fluid level in power steering pump every 1000 miles. To add oil to reservoir, remove cover and bring oil level to the "Oil Level" line embossed on side of reservoir housing using Automatic Transmission Fluid Type "A".

CONTINUED ON NEXT PAGE

BUICK AIR-POISE SUSPENSION (C ntinu d)

DRAINING HIGH PRESSURE AIR TANK: At least every 1000 miles, or more often if necessary, open the drain valve located at lower left end of tank and drain out the accumulated oil and water.



ADJUSTMENTS

ADJUSTMENTS: Trim H ight - Check operation of height control valves by applying weight to each side of rear bumper, one side at a time, and to center of front bumper. The car should raise back to normal trim height after weight has been added and should lower to normal after weight is removed. Check and correct tire pressures and inspect for binding in suspension system. Check shock absorber action and replace as necessary. Place car on a front end machine and proceed as follows:

Fr nt Trim H ight: Measure distance between top of compression bumper and lower side of frame side rail, directly above the compression bumper on each side. Distance should be 1 1/4"± 1/4", on all models. To correct, loosen two nuts and bolts at link clamp-bracket on front stabilizer bar and rotate clamp-bracket as necessary. Recheck trim height setting. *NOTE* If trim height varies between each side at the front, it could be caused by variation in the rear height valve trim setting. If this is the case, correct the front as closely as possible, correct trim heights at rear (see below), then recheck the front.

R ar Trim H ight: Check distance between tip on bottom of rear compression bumper and the strut rod-shock absorber bracket directly below the compression bumper. Distance should be 1 5/8" ± 1/4" (Exc. Station Wagon) 1 1/4" (Station Wagon). Repeat this check on opposite side. To correct, loosen the two bracket-to-height valve screws, on the front side of each bracket, and rotate height valves in the correct direction. *NOTE* - Holes in brackets are elongated to allow for valve rotation.

Supply Lin Pr ssur S tting: Bring air tank pressure to 200 lbs. Disconnect air return line on top of manual override valve and install hose, Tool J-7143. Pull manual lift knob on instrument panel to put car into lift position. Press Gauge J-6840 on end of Tool J-7143 and take a reading. Remove the gauge. If pressure is more than 125 lbs. remove boot from override valve and turn adjusting screw out (counterclockwise). Depress Schrader valve core for two or three seconds, then take another gauge reading. Repeat this procedure until correct gauge reading is obtained. If gauge reading is less than 125 lbs., proceed as above only turning the adjusting screw clockwise. When correct gauge reading is obtained, push manual lift knob all the way in to lower car to normal trim height. Depress Schrader valve core in hose to exhaust all air, then remove the hose. Connect air return line at override valve using a new "O" ring seal, and pull the manual lift knob to put car into the lift position. Check for leakage at fitting with a bubble solution. Push in manual lift knob to return car to normal position.

BUICK FR NT AIR SPRIN ASSEMBLY

Compressor Belt: Loosen compressor mounting bolts and adjust belt tension so torque required to slip belt on pulley is as follows: **(First Type Belt)** 30-35 ft. lbs., used belt; 40-45 ft. lbs., new belt. **(Later Type Belt, see note below)** 50-55 ft. lbs.

►*COMPRESSOR BELT PRODUCTION CHANGE:* A new "dacron" belt, Part No. 1186400 (Exc. Air Cond. Cars), Part No. 1186399 (Air Cond. Cars) was used in production beginning approximately Jan. 13, 1958. Later type belt is tightened to a different tension than earlier belts, see above.

Manual Override Control Cable: Push control knob fully in, then, on manual override valve, lift lever lightly by the stopscrew. If cable is properly adjusted, lever should have a slight amount of movement (not to exceed 1/8"). If necessary to adjust, loosen conduit clamp screw and slide conduit fully down then raise it 1/16". Tighten conduit clamp screw and recheck adjustment.

Manual Override Lever Stopscrew: Check control cable adjustment (see above) and adjust if necessary. If stopscrew is against its stop and there is still a leak past override plunger, adjust stopscrew as follows: Note position of screw, then loosen locknut and back screw out until air just stops leaking. (If backing screw out does not stop the air leak, stopscrew adjustment was not at fault). Back screw out an additional two turns (from point where air just stopped leaking), and tighten locknut.

TROUBLE SHOOTING

One Side Of Car Higher Than Trim Height: Rear height valve improperly adjusted. Plugged orifice or screen in one rear height valve exhaust fitting. Inoperative exhaust valve in one rear height valve.

Front Of Car Higher Than Trim Height: Front height valve improperly adjusted. Plugged orifice or screen in front height valve exhaust fitting. Inoperative exhaust valve in front height valve.

Entire Car Higher Than Trim Height (or car fails to trim after manual override setting is used): Manual override valve exhaust screen or orifice plugged. Manual override valve not properly adjusted.

One Side Of Car Lower Than Trim Height (with minimum of 150 lbs. tank pressure): Rear height valve not properly adjusted. Plugged intake valve orifice or screen in rear height valve. Inoperative intake valve in rear height valve.

Fr nt Of Car L w r Than Trim H ight (with minimum f 150 lbs. tank pr ssur): Front height valve not properly adjusted. Plugged intake screen or orifice in front height valve. Pressure regulator in manual override valve adjusted too low.

L ss Of Tank Pressure (car settl s on ne side whil park d): Leak at rear air spring, height valve, or connecting lines.

Loss Of Tank Pressure (car settles in front while parked): Leak at front air spring, height valve, or connecting lines. *(NOTE* - Due to normally greater weight on front of car, if there is a drop in tank pressure, the front intake check valve may leak back through supply line and allow front of car to settle).

Loss Of Tank Pressure (car stays at trim while parked): Leak at compressor check valve. Leaking intake valve core allowing supply leak into air spring raising car above trim height and opening exhaust valve to trim car. Repetition of cycle lowers tank pressure to air spring pressure.

Poor Handling While Driving (car rolls excessively): Cross flow control "tee" not restricting flow of air from one front spring to the other.

REMOVAL & INSTALLATION

AIR COMPRESSOR: Removal - Open drain cock and exhaust air. Loosen vented pulley nut and remove pulley and compressor belt. Disconnect power steering pump hoses and remove air inlet tee at compressor. Remove high pressure hose and check valve at compressor. Disconnect compressor-pump assembly from brackets and remove from car. Remove oil from compressor, then remove two compressor to pump bolts. Unless pump seal is to be replaced, install two guide pins, Tool J-7003 (3/8" - 16 x 3") in compressor to prevent damage to seals. Separate pump from compressor.

Installation: Install guide pins in compressor and carefully align pump on guide pins to avoid damage to seal, then push into contact with compressor. Remove pins and install two compressor to pump bolts. Tighten to 25-30 ft. lbs. Mount compressor in bracket and install bolts, but do not tighten. Connect high pressure hose and check valve to compressor. Connect inlet tee at compressor, then connect power steering hoses to pump. Install compressor pulley and belt and securely tighten vented pulley nut. Adjust belt tension (see above) and tighten mounting bolts. Fill reservoir with Dynaflow fluid, run engine, and check for leakage.

FRONT AIR SPRINGS: Removal - Raise front of car and support with jack stands placed at front under frame side rails. Remove tire and wheel assembly. Remove air spring dome outer attaching bolt (on top of crossmember and below cutout in upper control arm), then remove inner attaching bolt (located approximately six inches toward center of crossmember from outer bolt). Remove spring nut at bottom of pilot bearing. Disconnect height control valve link from clamp bracket on stabilizer bar, and disconnect air line at fitting on air spring dome. *(NOTE* - Air will be exhausted from both front air springs, but will not affect rear). Place floor jack under spring seat but do not raise car off jack stands. Disconnect stabilizer bar link at lower control arm, then disengage lower ball joint stud from steering knuckle *(see "Buick Front Suspension" in Suspension & Wheel Alignment Section).* Remove air spring assembly.

Installation: Position air spring assembly in crossmember opening and raise lower control arm assembly

CONTINUED ON NEXT PAGE

BUICK AIR-POISE SUSPENSION (C ntinued)

into position and install lower ball joint stud in steering knuckle. Position plunger pilot bearing into hole in spring seat adapter and secure with spring nut. Place jack under spring seat but do not raise car off jack stands. With one man below to position and hold spring up, and another on top, replace dome bolts and lockwashers. Connect air line to fitting at air dome using a new sealing ring and connect stabilizer bar link to lower control arm. Fill air tank with air and operate height control valve link to pressurize air spring. Check for leaks, then connect height valve link to clamp bracket on stabilizer bar. Remove car from jack stands.

REAR AIR SPRINGS: Removal - Raise rear of car and place jack stands under frame side rails, then lower jack and allow axle assembly to lower close to full rebound position. Disconnect height control valve link at axle strut rod on spring being removed. Disconnect air line fitting on spring, allowing air to exhaust from spring. Remove two bolts retaining plunger bearing plate to axle housing and pull plunger loose from diaphragm center plug. Remove plunger and bearing plate assemblies. Remove two self-tapping screws at dome upper and side retainer brackets, then remove air spring.

Installation: Reverse removal procedure and note the following: Install new sealing ring when connecting air line at dome fitting. Before connecting height valve link to strut rod, raise height valve lever carefully to allow air to inflate air spring assembly. Check for air leaks. *CAUTION - N v r disconnect radius rod or torque tube unless all air is exhausted from rear air springs. If shock absorbers are to be removed, disconnect height control valve links at axle strut rods before disconnecting shocks.*

FRONT HEIGHT CONTROL VALVE: Removal - *(CAUTION - Never force a height control valve lever hard against its stop in either direction, as inner valve lever would be bent, changing the valve setting).* Open drain cock and exhaust all air from tank. Raise front of car and support with jack stands under front of frame side rails and remove jack. Disconnect height valve link at clamp bracket on stabilizer bar, then remove front spring crossmember lower cover. Disconnect all air lines at height control valve allowing cross flow control tee to remain with air lines. Remove two valve bracket mounting bolts at front of crossmember and remove bracket and valve assembly.

Installation: Reverse removal procedure and note the following: Before replacing spring crossmember lower cover, fill air tank and operate height control valve to pressurize springs. Check for leakage and valve operation.

REAR HEIGHT CONTROL VALVE: Removal - Raise car with a jack placed at center of rear axle housing. Place a block of wood (½" shorter than normal trim height) between frame and axle housing at center, then place jack stands under axle housing and remove jack. Open drain cock on tank and exhaust all air. Disconnect height valve link at valve lever and disconnect all lines at height control valve. Remove two brackets to valve body bolts and remove valve.

Installation: Reverse removal procedure and note the following: Install new "O" ring seals on all air line fittings. Fill air tank and raise height control valve lever to fill air spring and valve body. Check for leakage, then connect height control valve link to lever. Check trim height and correct as necessary. *See "Adjustments" above.*

MANUAL OVERRIDE VALVE: R m val - Open drain cock and exhaust all air. Raise car at front and disconnect all air lines at override valve. Disconnect Bowden control wire assembly, then remove valve-to-bracket bolt at lower front of valve and remove valve.

Installation: Reverse removal procedure and note the following: Fill air tank, then check adjustment of Bowden control cable for correct lift action. Operate lift control knob on instrument panel and place car into lift position. Check for leakage at all override valve fittings, then lower car to normal height.

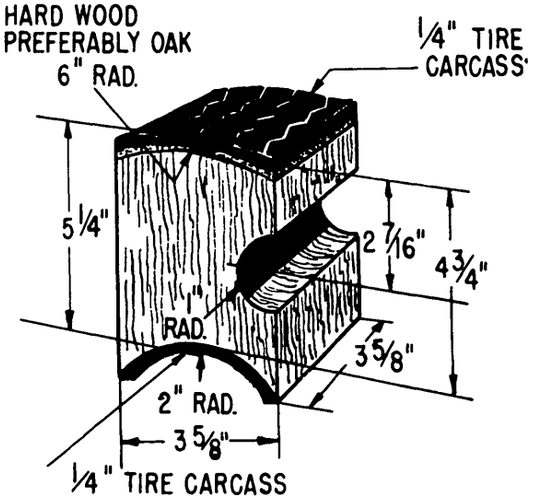
CADILLAC AIR SUSPENSION (EXCEPT 1957-58 ELDORADO BROUGHAM)

Cadillac, Exc. C mm. (1958-60) S N t Bel w.

►*1957-58 ELDORADO BROUGHAM NOTE: For data on thes models, se "1957-58 Cadillac Eldorado Brougham Air Suspension".*



►CHANGES, CAUTIONS, CORRECTIONS

►*SERVICE CAUTIONS:* Before working under the car, jacking it up, or raising it on a hoist, the following precautions must be taken to prevent personal injury or damage to the car.

Raising Car (On a Jack) - Before raising car on a jack, pull the Manual Valve on instrument panel to the full OUT position which will raise the car to its full rebound position. *CAUTION* - Never raise rear of car with shock absorbers disconnected. Rear shocks serve as rear suspension rebound stops and if disconnected, the car could be raised off its suspension, causing a separation of the rear suspension air spring assemblies.

Raising Car (On a H ist) - Before raising car on a hoist, pull the Manual Valve on instrument panel to the full OUT position which will raise the car to its full rebound position. *NOTE* - Hoisting equipment that engages suspension, axle, or wheels is preferred. If a frame contact type hoist is used the following precautions must be taken: Use special adapters to assure engagement with car frame at points indicated in illustration. Care should be taken to prevent hoist adapters contacting any part of the No. 2 body hanger. Hoist contact at rear should be at outer ends of the No. 4 body mounting brackets. In no case should rear contacts be less than 40" apart. *CAUTION - Do not allow hoist to contact rear low r control link front mounting brack t.*

►*TOWING THE CAR: (CAUTION - Do not tow car with r ar wh els on th ground unless propeller shaft is disconn ct d. Th only xc ption to this would be when distanc t b tow d is only a few blocks).* When towing with front or rear wheels off the ground with air in suspension system, pull out the manual valve control handle on instrument panel to lock air in the suspension system. Then depress service valve core on accumulator tank and exhaust enough air to let the car down to approximately normal height. When towing car with front end raised off ground with no air in suspension system, first raise rear of car and install support blocks (see illustration for dimensions of block) upright in front of shock absorbers, between rear axle housing and frame side members. Lower rear end, then raise front of car with truck hoist, making certain that a minimum of 6" clearance remains between lower edge of rear bumper and ground. For towing with rear wheels raised off ground, first raise front end and install support blocks, with small groove against rubber compression bumpers on lower suspension arms and large groove encircling shock absorbers. Lower front end, then raise rear end with truck hoist, making certain there is a minimum of 6" clearance between lower edge of front bumper and ground. Secure steering wheel to hold front wheels in straight ahead position. *(NOTE - T w lin s must b hook d to low r control arms at front, or r ar axl housing at r ar).* With all wheels on

CADILLAC FRONT TOWING BLOCKS

ground and no air in suspension system, it is permissible to tow or push car without use of support blocks. DO NOT attempt this except on hard smooth pavement, and limit towing speed to 10 MPH. When towing car using the above blocks, do not exceed 25 MPH on rough roads.

►*1958 AIR DOME BALL CHECK FLOW VALVE PRODUCTION CHANGE (To Permit Front & Rear of Car to Raise Simultaneously):* Starting with Eng. No. 141902, the air dome ball check flow valve has been altered so air flow is restricted at both intake and exhaust. Later type valves have the same part number as used previously, however, they can be identified by a daub of red or blue dye on top of hex, or by a groove etched around hex of fitting. When installing new valve, the valves at all four air domes must be changed if they are not the later type.

►*1958 AIR PRESSURE WARNING LIGHT PRODUCTION CHANGE:* Beginning with Eng. No. 151370, air pressure tell-tale light bulb in instrument panel of Series 60, 62 & 75 has been eliminated. In the event of air pressure switch failure on cars before the above engine number, electrical lead at switch should be disconnected and lead cut off close to point where it leaves harness, then tape wire at harness. Replacement pressure switches are not available for service installation.

►*COMPRESSOR OIL LEAKAGE OR SLINGING FROM BREATHER HOLE IN PULLEY NUT CORRECTION:* This condition may be caused by leakage between manifold in steering pump tank and the tank itself, causing a gravity feed to flood compressor crankcase when engine stopped. If manifold is distorted (caused by over-torqueing cover holddown screw), replace manifold. Check gasket under manifold and tighten manifold to tank attaching screws securely. If leakage cannot be traced to distorted manifold, it will be necessary to replace the compressor.

►*HARSH RIDING OR ERRATIC LEVELING OF CAR CORRECTION:* Excessive friction in front suspension lower control arm pivot shafts may be cause of this condition. If lubrication will not correct excessive friction, it is suggested that new shaft and bushing kits be installed.

►*AIR DOME FLOW VALVE INSTALLATION CAUTION:* When installing the flow valve in air spring dome, DO NOT tighten in excess of 5-10 ft. lbs. Excessive tightening may break the fitting.

►*ICE FORMATION IN SYSTEM CORRECTION:* To prevent ice from forming in air suspension system during cold weather, add one-half pint of methyl (wood) alcohol to the accumulator tank each time car is lubricated.

DESCRIPTION: Air springs, consisting of an air dome and a rubber bellows assembly attached to frame and a piston assembly attached to lower control arm (front), control link (rear), replace the conventional coil springs at both front and rear of car. Normal riding height is maintained automatically by two height control valves (rear), one control valve (front). A manually operated lift valve is located on frame right side rail (1958), inside front face of left hand No. 1 body mounting bracket (1959-60), and controlled by a lift control handle on the instrument panel. This valve, when pulled out, provides air to all four springs, causing the car body to be raised above its normal height. Basic components of system operate as follows:

Air Compressor: Single stage, two cylinder reciprocating type rated at 3.5 cu. ft. of air perminute. The compressor shaft is splined to the power steering pump rotor and both units are mounted together. Oil supply for compressor lubrication is obtained from power steering pump reservoir. Fresh air is drawn into the compressor from a line connected to the carburetor air cleaner.

Accumulator Tank: Mounted forward of radiator (1958), in front and to left (1959-60). Maintains a supply of high pressure air and traps moisture, dirt, and oil. This tank is equipped with a blow off valve and a service valve (1958 models included a pressure switch for operation of air pressure tell-tale light on instrument panel).

Manual Lift Override Valve: Located on frame right hand side rail (1958); on left hand No. 1 body mounting bracket (1959-60) and operated by a cable connected to a handle on the instrument panel. The car body can be raised to a maximum allowed by rebound bumpers by pulling manual control valve to its full out position. Pressure in the system will be trapped with handle in the full out position and car will remain at the full rebound position until handle is pushed in. *CAUTION - If handle is left in a middle position, air can bleed from system.* Air pressure regulator valves are also included in manual valve assembly to control pressure in system.

Rear Leveling Valves: A leveling valve is located on each frame side rail and is connected by linkage to the rear control link. These valves not only act to control height of rear of car but also to maintain proper height of right and left side of car to maintain it in a level position

CONTINUED ON NEXT PAGE

CADILLAC AIR SUSPENSION (C ntinu d)

under varying load conditions.

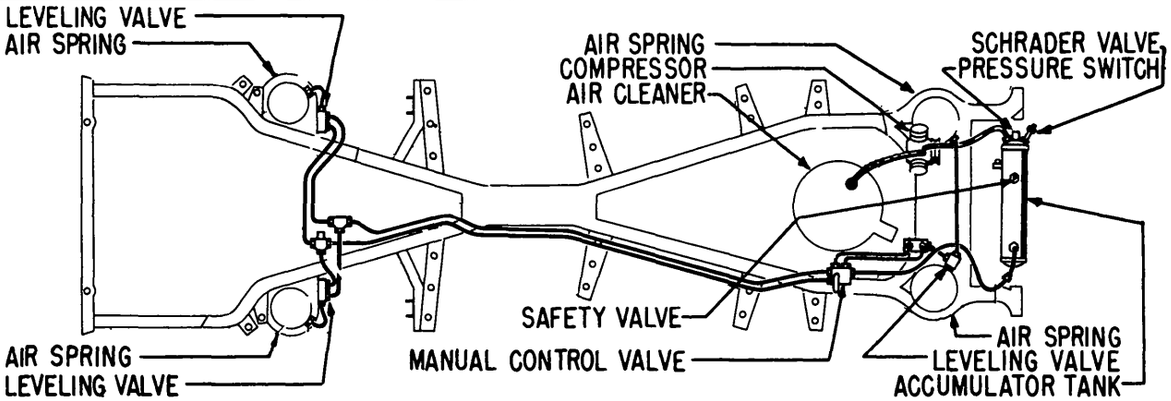
Fr nt Leveling Valve: The single front leveling valve is mounted on the number one crossmember and is actuated by linkage connected to the front stabilizer bar. This valve increases or decreases air pressure in both front air springs to maintain proper car height under varying load conditions.

►*1960 FRONT LEVELING VALVE NOTE:* Front leveling valve utilizes two port adapters (one to each front wheel suspension bellows) in place of the single valve previously used. A rubber umbrella-type check valve core is used in intake valve adapter in each leveling valve instead of the tire-type core previously used.

Air Springs: Each unit consists of a metal air dome and rubber bellows assembly attached to car frame; and a piston or plunger assembly attached to lower control arms at front, and to the control link at the rear. Pressure in the air springs is controlled automatically by the leveling valves. An orifice valve at each air spring restricts the flow of air in both directions so air spring action is not subject to sudden changes in loading conditions.

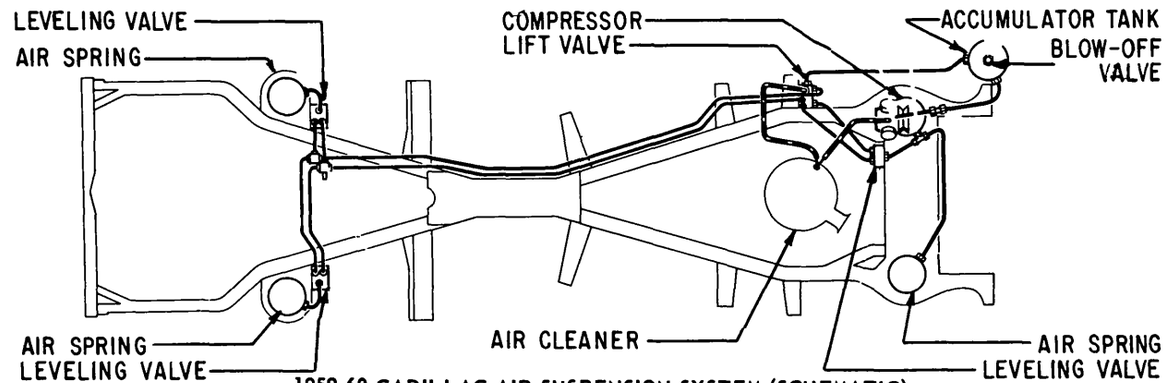
Pr ssure Blow-Off Valve: This unit is located in the rear intake line tee and is set for 150-165 lbs. pressure. In the event a pressure regulator should fail with the lift valve open, damage to bellows assemblies would be prevented by the excessive pressure escaping through the blow-off valve.

LUBRICATION: Air Compressor - Every 2000 miles, check fluid level in power steering reservoir and fill to mark on tank with Automatic Transmission Fluid Type "A".



DRAINING ACCUMULATOR TANK. When car is lubricated (every 2000 miles), open the drain cock located on lower side of tank and drain off accumulated oil, water, and dirt.

►*1958 ACCUMULATOR TANK DRAIN VALVE CHANGE:* Accumulator tank drain valve has been eliminated beginning with Eng. No. 102500. On cars not equipped with drain valve, condensate can be drained from tank through service valve by cautiously opening service valve not more than three turns. Allow tank pressure to be completely relieved, then remove service valve from tank and allow condensate to drain out.



ADJUSTMENT

ADJUSTMENTS: Compressor Drive Belt - Place Belt Tensioning Gauge, J-6733 midway between pulleys. Loosen compressor mounting bolts and tighten belt until shoulder of gauge is between lines on barrel of gauge. Hold this tension and tighten compressor mounting bolts.

►*TRIM HEIGHT CHECKING NOTE:* Maintain 125 lbs. minimum in accumulator tank when checking trim height. Place car on a level surface (wheel alignment machine, or drive-on type hoist), then normalize position of air springs by working bumper up and down, permitting car to assume its normal standing height. Make sure that leveling motion has stopped, then proceed as follows:

1958 CADILLAC AIR SUSPENSION SYSTEM (SCHEMATIC)

1959-60 CADILLAC AIR SUSPENSION SYSTEM (SCHEMATIC)

1958 MODELS

Front Trim Height: With car height normalized (see above), measure distance from top of left lower suspension arm to center of second lower rivet from front of frame. This distance should be 4 5/16" ± 3/16" (Exc. Series 75), 5" ± 1/4" (Series 75). If not within specifications, loosen adjusting nuts on leveling valve adjusting link and move control arm as required to bring measurement within specifications. Allow sufficient time for leveling action to take place, then tighten adjusting nuts and recheck measurement Check standing height on right side. If measurement varies from left side by more than 1/4", check and adjust rear trim height (see below).

Rear Trim Height: With car normalized (see above), and front trim height adjusted, measure distance from top of rear axle housing to underside of frame at each side of car. This measurement should be 4 1/2" ± 1/4" (Exc. Series 75). 5 3/8" ± 1/4" (Series 75). The rear trim height should be equal within 1/8" on both sides of car. If not within specifications, loosen adjusting nuts on leveling valve adjusting link and raise or lower adjusting link until measurement is within specifications. Allow sufficient time for leveling action to take place, then tighten adjusting nuts and recheck measurement. Recheck front trim height (see above), and correct as necessary.

1959-60 MODELS

Front Trim Height: With car height normalized (see above), measure distance from top of left lower suspension arm to center of second lower rivet from front of frame. This distance should be 4 5/8" ± 3/16" (Exc. Series 75), 5 11/32" ± 3/16" (Series 75). If not within specifications, loosen adjusting bolt on leveling arm and move leveling valve control arm as required to bring measurement within specifications. Allow sufficient time for leveling action to take place and recheck measurement. If measurement varies from left side by more than ¼", check and adjust rear trim height (see below).

Rear Trim Height: With car normalized (see above), and front trim height adjusted, measure distance from top of rear axle housing to underside of frame at a point directly above axle housing (at each side of car). This measurement should be 4½" ± ¼" (Exc. Series 75), 5 13/32" ± ¼" (Series 75). The rear trim height should be equal within 1/8" on both sides of car. If not within specifications, loosen adjusting bolt on leveling valve arm and raise or lower arm until measurement is within specifications. Allow sufficient time for leveling action to take place, then tighten adjusting bolt and recheck measurement. Recheck front trim height (see above) and correct as necessary.

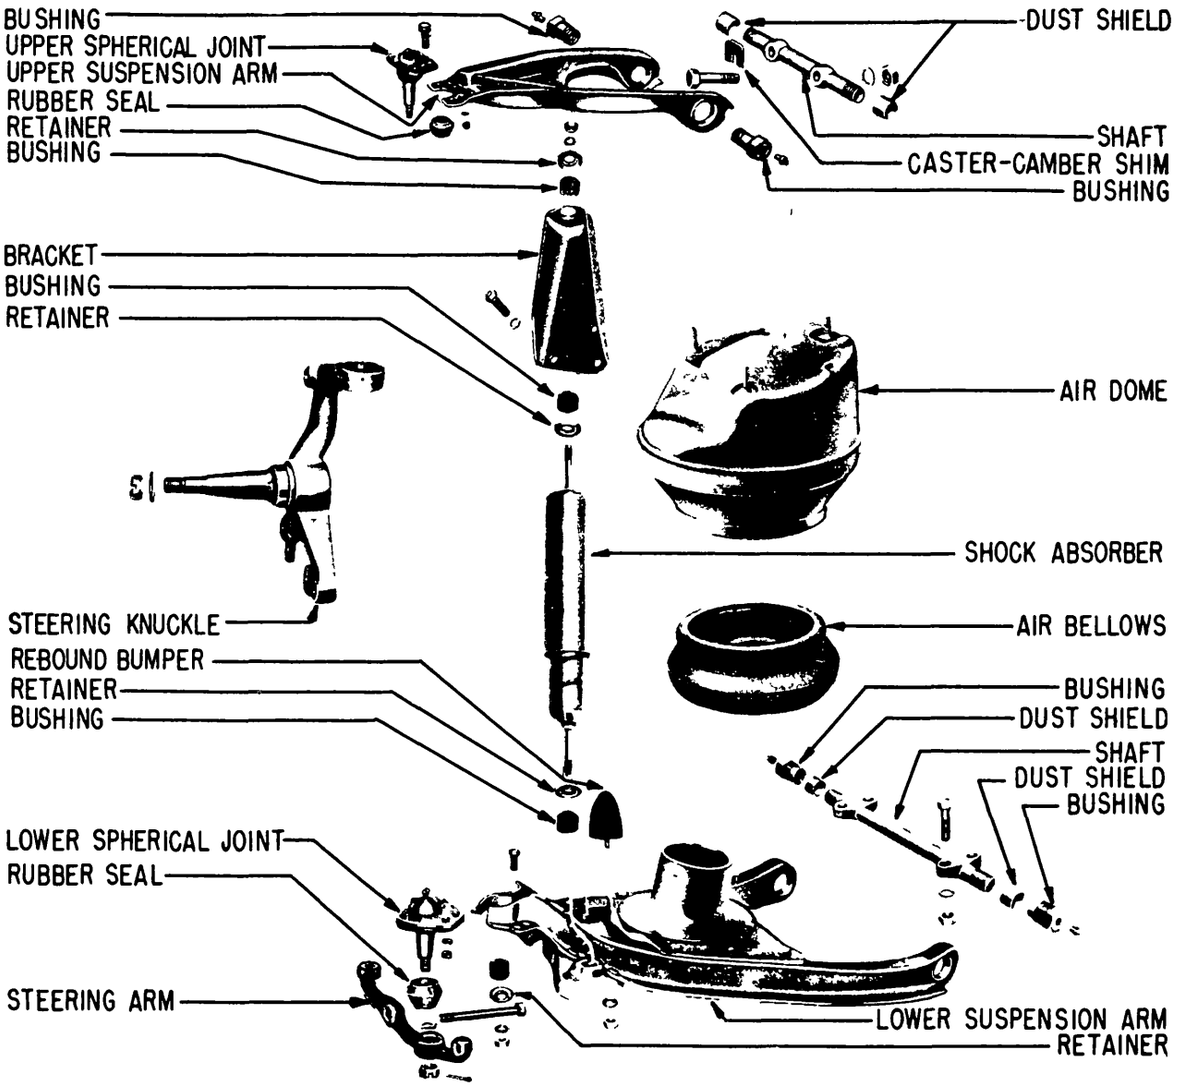
CADILLAC AIR SUSPENSION (C ntinu d)

ALL MODELS



Fr nt End Adjustm nt: Toe-In adjustment should be 1/16" ± 1/32" on all cars with air suspension. All other adjustment specifications are the same as for conventional cars with coil springs. S *"Front Suspension" on Car Mod l pag .*

1958 MODELS

Lin Pr ssur Regulat r: Raise car and place jack stands under front and rear frame side members, then exhaust air from system by opening drain cock on bottom of accumulator tank. Disconnect high pressure air line to front air springs at fitting on lift valve, making certain that "0" ring seal remains in lift valve seat. Connect Air Ride Hose & Fitting, Tool J-7143, to lift valve front high pressure line fitting, routing hose so it does not contact exhaust manifold. Close drain cock and replenish air supply in accumulator tank so pressure is above 125 lbs. (Series 60 & 62), 150 lbs. (Series 75). Check pressure with Gauge J-6840. Run engine at slow idle to maintain pressure during adjustment. Depress service valve stem on end of Air Ride Hose, J-7143, momentarily allowing air to escape (this actuates regulator valve to insure it is not stuck). Check regulated air pressure at service valve end of Air Ride Hose, using Air Pressure Gauge, J-5880. Pressure should be 125 lbs. ± 5 lbs. (Series 60 & 62), 150 lbs. ± 5 lbs. (Series 75). If pressure not within these limits, proceed as follows: Remove rubber regulator boot from top of lift valve, then using a short screwdriver, rotate regulator screw (clockwise to increase pressure, counterclockwise to decrease pressure). Depress valve stem on Air Ride Hose to actuate regulator valve, then check pressure. If not correct, repeat the above procedure. Replace rubber boot on regulator valve and remove Air Ride Hose and checking gauge. *(NOTE* - It will be necessary to exhaust air from system before removing Air Ride Hose).

1959-60 MODELS

Lin Pressur Regulator: Raise car and place jack stands under front and rear frame side members, then exhaust air from system by opening service valve on bottom of accumulator tank. Disconnect high pressure air line to front springs at fitting on air lift valve, making certain that "O" ring seal remains in lift valve seat. Connect Air Ride Hose & Fitting, Tool J–7143 to lift valve front high pressure line fitting, routing hose so it does not contact exhaust manifold. Close service valve and replenish air supply in accumulator tank so pressure is above 175 lbs. Check pressure with Gauge J–6840. Run engine at slow idle to maintain pressure during adjustment. Depress service valve stem on end of Air Ride Hose, J–7143, momentarily allowing air to escape (this actuates regulator valve to insure it is not stuck). Check regulated air pressure at service valve end of Air Ride Hose, using Air Pressure Gauge, J–6840. Pressure should be 125 lbs. ± 5 lbs. (Series 60, 62 & 64); 150 lbs. ± 5 lbs. (Series 67). If pressure not within specifications, proceed as follows: Remove rubber regulator boot from top of lift valve, then using a screwdriver, rotate regulator screw (clockwise to increase pressure, counterclockwise to decrease pressure). Depress valve stem on Air Ride Hose to actuate regulator valve, then check pressure. If not correct, repeat the above procedure. Replace rubber boot on lift valve and remove Air Ride Hose and checking gauge. *NOTE – It will be necessary to exhaust air from system before removing Air Ride Hose.*

CADILLAC FRONT SUSPENSION ASSEMBLY

TROUBLE SHOOTING

Air Pressure Warning Light Remains On: Low pressure in system or grounded switch or connecting wire.

Car Will N t R turn T L v l P siti n (Air Pr ssur Normal): Front or rear leveling valve control links not adjusted properly. Leak or obstruction in high or low pressure lines.

Air System Too Sensitive (Resulting In Excessive Leveling Action): Leveling valve dashpot does not operate properly.

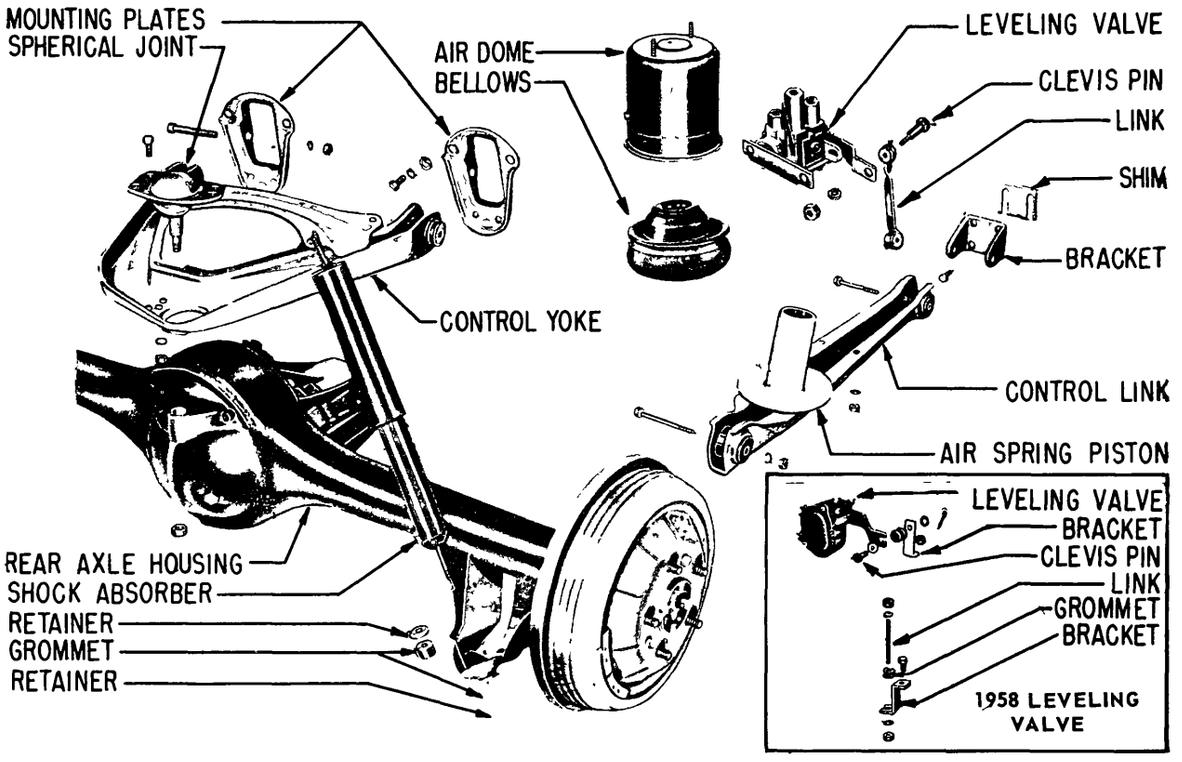
Air Spring Inoperative: Leakage in bellows, air dome, air lines, or insufficient air pressure. Defective leveling valve, lift valve, or orifice valve.

R ad Sh cks: Incorrect standing height, if not due to shock absorbers, tires, or front suspension parts.

CONTINUED ON NEXT PAGE

CADILLAC AIR SUSPENSION (C ntinu d)

REMOVAL & INSTALLATION



AIR COMPRESSOR: Removal - Remove power steering reservoir cover and syphon off all fluid. Disconnect hydraulic hoses at pump and cap the ends. Remove two screws retaining pump to rear face of air suspension compressor. Pull pump off splined compressor shaft and discard "0" ring seals. Disconnect fresh air inlet, then disconnect high pressure fitting on compressor. Remove drive belt and pulley, then remove two screws holding compressor to bracket, and remove compressor.

Installation: Reverse removal procedure and note the following: Adjust belt tension (see above), and check all high pressure fittings for leakage.

FRONT SPRINGS: Removal - Raise car and place jack stands under front and rear frame side members and remove wheel. Exhaust air from system (open drain cock on bottom of accumulator tank). Disconnect front shock absorbers at lower suspension arm and remove lower spherical joint cotter pin and nut. Strike steering arm with a hammer in area of spherical joint to break joint loose. Raise lower suspension arm until spherical joint is free, then allow suspension arm to swing down. Push on one side of rubber bellows until bead unseats from air dome, then pull bellows out of dome, being careful not to overstress bead or damage rubber seal. To remove air dome, disconnect air line at dome (two lines on right side). Remove three nuts retaining air dome to frame spring tower, and remove air dome.

Installation: Reverse removal procedure and note the following: Coat outside of bellows with silicone to prevent rubber to metal contact, then insert bellows completely inside the air dome, being careful not to overstress bead or damage rubber seal. Position bellows with bead seat up, then grasp bellows with both hands and pull into position. *(NOTE* - An alternate method is to disconnect dome air line and orifice valve, then using an air hose, bellows can be forced into position). Whichever method is used, make sure that bellows is seated properly in air dome. Check for air leakage.

REAR AIR SPRINGS: Removal - Raise car and place jack stands under front and rear frame side members. Exhaust all air from system (open drain cock on bottom of accumulator tank), then push on one side of rubber bellows until bead unseats from air dome. To remove air dome, disconnect air line at dome and remove two nuts retaining air dome to frame spring tower.

CADILLAC AIR SUSPENSION (REAR) WITH 1959-60 LEVELING VALVE

Installation: Reverse removal procedure and note instructions for installation of front bellows (above).

FRONT LEVELING VALVE: Removal - Raise car and place jack stands under front and rear frame side rails, then exhaust all air from system (open drain cock on bottom of accumulator tank). Remove two screws securing top of leveling valve bracket to front frame crossmember (screws may be reached through engine compartment). Disconnect adjusting link at control arm *(CAUTION* - Do not disturb adjusting nuts). Remove remaining bracket mounting bolt and remove leveling valve and bracket.

Installation: Reverse removal procedure, using new square cut tube fitting gaskets at air line fittings. Check fittings for leakage.

REAR LEVELING VALVE: Removal - Raise car and place jack stands under front and rear frame side rails, then exhaust all air from system (open drain cock on bottom of accumulator tank). Disconnect adjusting link at control arm, then disconnect three lines from leveling valve (a slight amount of air may discharge). Remove bolts retaining valve to frame spring tower and remove valve.

Installation: Reverse removal procedure and install new "0" ring seals at air line fittings. Check fittings for leakage.

LIFT VALVE: Removal - Raise car and place jack stands under front and rear frame side rails, then exhaust all air from system (open drain cock at bottom of accumulator tank). Disconnect Bowden cable at lift valve and disconnect five air lines at valve. Remove two bolts retaining valve to frame member and remove valve.

Installation: Reverse removal procedure and note the following: Use new "0" ring seals on all fittings. Connect Bowden cable, making sure that control handle on instrument panel is all the way in and that control lever on lift valve is all the way down. Check lines for leakage.

OVERHAUL

LEVELING & LIFT VALVES: *Se "Air Suspensi n L veling & Manual C ntr l Valves"*

AIR COMPRESSOR: *Se "Air Suspension Air Compressors"*

1957-58 CADILLAC ELDORADO BROUGHAM AIR SUSPENSION

Cadillac Eldorad Br ugham (1957-58)

►CHANGES, CAUTIONS, CORRECTIONS

►*AIR COMPRESSOR OIL INLET FITTING PRODUCTION CHANGE:* **Starting with Engine No 5770-122962, a new oil inlet fitting, Part No 5534103 is used in production and is recommended for installation on previous cars to prevent varnish deposits blocking the inlet fitting orifice**

►*REAR AXLE PINION ANGLE ADJUSTMENT (To Prev nt Pr pell r Shaft Vibration): See "Cadillac Rear Suspensi n".*

►*AIR SUSPENSION ELECTRICAL CIRCUIT CHANGE:* **Wiring changes were made in later production cars to include a new 25 ampere fuse in air compressor and lockout solenoid feed circuits Fuse is located under dash, near fuse block Protective relay-to-ground has been rewired through generator armature instead of through oil pressure tell-tale switch**

►*TOWING CAUTION: Instructions for various methods of towing car are diff rent as noted below. NOTE -When towing with front or rear wheels raised off the ground, disconn ct battery strap to prevent any leveling action.*

Air in Susp nsi n Syst m (Front End Raised) - Hook chain around front bumper mounting bar through opening in underside of impact bar above fog lights (both sides). Attach both ends of chain to tow truck spreader bar. Place protective padding around front bumper bar extensions, hold a 6 ft length of 2" pipe under bumper bar guards parallel with front bumper Then raise front end of car with truck hoist until spreader bar and chains are bearing against length of 2" pipe and front end of car is raised sufficiently for towing purposes *CAUTION - Check rear end to assure ground clearance at spare tire w ll.*

N Air in Susp nsi n System (Front End Raised) - Attach tow chains as for "Air in Suspension System" above, then remove front wheels and lower front end of car until there is 6" clearance between lower edge of rear license plate holder and ground *Disconnect propeller shaft if being towed more than a few blocks.*

R ar End Rais d - Turn front wheels to straight ahead position and tie steering wheel securely to prevent movement of front wheels while towing Hook chain around rear bumper outer mounting bar through opening under rear bumper exhaust ports (both sides) Place protective padding on under side of rear bumper outer impact bars where chain contacts, and connect chain to spreader bar of tow truck Raise rear end of car with tow truck *CAUTION - Make certain that front bumper is clear of ground.*

All Wheels on Ground - Hook chain around front bumper mounting bar through opening on underside of impact bar above fog lights *CAUTION - Do not tow car at speeds over 10 MPH. Disconnect propeller shaft if being towed more than a few blocks.*

►*HOISTING CAUTION:* Use lifting equipment that engages suspension, axle, or wheels. When using a frame contact hoist, special adapters must be used on hoist rails to assure engagement with frame at a point 34" to rear of front wheel centerline *(CAUTION - Do not allow adapters to contact any portion of No. 2 body hanger)* and at extreme tips of widest crossmember which is approximately 97" to rear of front wheel centerline. In no case should rear contact points be less than 40" apart

►*RAISING REAR OF CAR CAUTION:* Never raise rear end of car with rear shock absorbers disconnected as it is possible to raise rear end off its suspension and result in separation of rear air spring assemblies

►*SERVICING CAUTION: Do not open any door or turn ignition on when any wheel of the car is off the ground, such as changing a tire or when car is on a hoist.*

►*AIR FILTER LOCATION & CLEANING NOTE:* Three pourex filters located in the high pressure air line fitting at top left side of control solenoid and in the two exhaust line fittings at lower right front and bottom of unit must be cleaned at six-month intervals (more often if car is operated in sandy or desert areas) *See "Overhaul" below for cleaning procedures.*

►*AIR COMPRESSOR OIL FILTER LOCATION & CLEANING NOTE:* A pourex type filter located in the compressor oil inlet fitting must be cleaned each time the engine oil filter is changed *See "Overhaul" below for cleaning procedures.*

DESCRIPTION

DESCRIPTION: This new suspension consists of pressurized diaphragm units replacing the conventional coil and leaf type springs Air, under 110-130 lbs pressure, is controlled by three leveling valves (two at the rear and one at front) and maintains car level at a pre-determined height from the ground regardless of load The front suspension is basically the same as on conventional models having upper and lower control arms connected to steering knuckle by spherical joints. The rear suspension consists of two lower control links and an upper control yoke which are connected between car frame and rear axle housing. A pressure of 110-130 lbs. is maintained in a 500 cu. in. accumulator tank by an electrically driven, low capacity, piston type compressor mounted on the car generator An oil pressure switch in engine oil line prevents compressor from operating except when engine is running Solenoid valves control air flow to and from the air spring units when car ignition is turned on or when a door is opened

OPERATION

OPERATION: Leveling - (All Doors Closed - Igniti n Off) - No leveling occurs. Restriction solenoid and lockout solenoid are closed. High pressure air from accumulator passes through restriction in restriction solenoid and stops at closed lockout solenoid. Lockout solenoid prevents movement of air to and from air springs

Any Door Open - Ignition On or Off - Both the restriction solenoid and lockout solenoid are open which allows high pressure air to flow unrestricted to the three leveling valves. If weight is added, raising leveling valve arm, the inlet passage is opened allowing air to flow to air spring. If weight is removed, leveling valve arm is lowered, opening the exhaust passage and allowing air to escape from spring

All Doors Closed - Ignition On - *(NOTE - Two-second delay dashpots in leveling valves prevent any leveling action taking place when wheels move rapidly up and down. Intake or exhaust action occurs only when car is above or below normal standing height for a sustained period of more than two seconds).* The restriction solenoid is closed and the lockout solenoid open. Air to or from the springs is metered as it passes through the restriction solenoid as regulated by the leveling valves

Door Open - Ignition On - When more weight is added to one side, or when car is parked on an uneven surface, both the restriction and lockout solenoids are open. High pressure air from the accumulator flows unrestricted through control solenoid to leveling valves and levels the car as required by change in weight distribution.

Air C mpr ssor: This unit is a low capacity, piston type

CONTINUED ON NEXT PAGE

CADILLAC ELDORADO BROUGHAM (C ntinu d)

compressor having an integral electric motor controlled by a pressure switch. Pressure is maintained in the accumulator at 110-130 lbs. The compressor is lubricated from the engine oil system which provides a restricted flow of oil into compressor reservoir. A standpipe in the compressor reservoir returns overflow to engine oil pan. The compressor electrical circuit is energized only when engine is running due to the feed circuit being connected to engine oil pressure tell-tale switch.

C ntr l Solenoid: Consists of two lockout solenoid valves and two restriction solenoid valves. One of each type valve is in the inlet circuit and the other in the exhaust circuit to the leveling valves. The lockout valves, when closed, prevent flow of air to or from the leveling valves. The restriction valves, when open, provide fast leveling (with car standing), and slow leveling (with car moving). Both lockout valves open together as do the two restriction valves. Operation of the valves is controlled by ignition switch and door switches.

Accumulator Tank: This tank stores enough air at high pressure to re-level the car from curb weight to a five passenger load without additional air from the compressor. A pressure switch on the accumulator actuates a red light on instrument panel when pressure falls below 82 lbs. pressure (required for car leveling). A petcock at lower side of tank permits periodic draining of dirt and moisture. A "Schrader" valve located in a tee fitting in air line leading from the air compressor is provided to fill accumulator with a service air hose.

R stricted "Tee" Check Valve: Due to a single leveling valve being used for both front air springs, a check valve is provided to allow rapid flow of air between front springs and control solenoid for fast leveling, and at the same time restrict the air flow between the front air springs during car roll or cornering. This valve is mounted on frame front crossmember just to right of left hand radiator support bracket.

TROUBLE SHOOTING & DIAGNOSIS

► *TROUBLE SHOOTING & DIAGNOSIS NOTE: The following trouble shooting & diagnosis data indicates conditions and corrections peculiar to Cadillac Air Susp nsion only. Conditions arising from incorrect wheel alignment, loose or worn steering linkage, spherical joints, shock absorbers, or worn tires should be corrected in the usual manner.*

ROAD SHOCKS: May be caused by incorrect standing height or wrong type or size of tires. *See "Adjustment" below.*

AIR PRESSURE WARNING LIGHT REMAINS ON: Check and correct any air leaks. Check operation of air compressor and solenoid. Check for grounded switch or connecting wire.

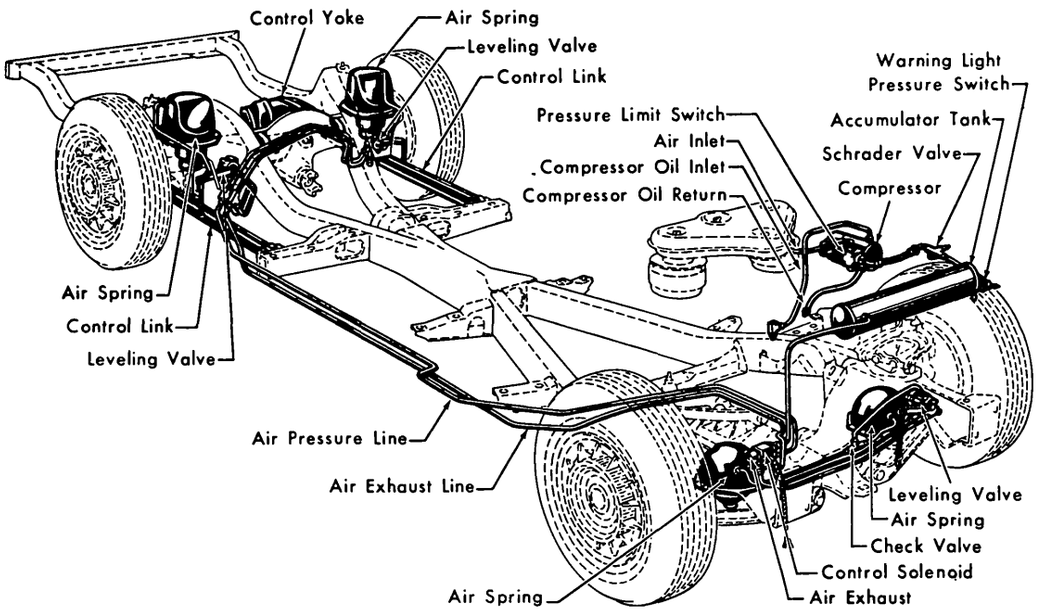
AIR COMPRESSOR OPERATES CONTINUOUSLY: Pressure control switch diaphragm ruptured. Air leak in system. Valve plate in compressor head worn or broken. Pressure limit switch not functioning. Compressor relay defective.

CAR WILL NOT RETURN TO LEVEL POSITION (AIR PRESSURE NORMAL): Front or rear leveling valve control links not adjusted properly. Kink, leak, or obstruction in high or low pressure lines. Air compressor relay will not actuate. solenoid. Control solenoid not operating.

NO LEVELING ACTION WITH EITHER FRONT DOOR OPEN: An open circuit may exist between front door dome light switch and control solenoid relay. Control solenoid not operating.

NO LEVELING ACTION WITH EITHER REAR DOOR OPEN: An open circuit may exist between rear door transmission interlock switch and control solenoid relay. Control solenoid not operating.

AIR SYSTEM TOO SENSITIVE (EXCESSIVE LEVELING ACTION): Leveling valve dashpot does not delay valve action (replace leveling valve). Control solenoid restriction valve not operating. Defective dome light switch at front door hinge or transmission interlock switch at rear door.



AIR SPRING INOPERATIVE: Air leak in diaphragm, air dome, or air lines. Defective leveling valve, control solenoid, pressure switch, compressor, or compressor relay. Insufficient air pressure. Defective restriction "Tee" valve. Loose electrical connections.

HARD RIDING: Insufficient lubrication. Tires over-inflated. Shock absorbers faulty. Standing height incorrect. Scuffed air spring diaphragm, Insufficient air pressure.

BOTTOMING OF REAR SPRINGS: Incorrect standing height. Worn or defective rear suspension linkage. Insufficient air pressure in system.

ADJUSTMENT

FRONT WHEEL ALIGNMENT: Alignment and adjusting procedures are the same as for conventional models. *See "Cadillac Front Suspension".*

CADILLAC ELDORADO BROUGHAM AIR SUSPENSION SYSTEM

STANDING HEIGHT: *NOTE - Air pressur in accumulator tank should be maintained at 90 lbs. or abov wh n checking standing height. All wh ls must b on a level surface when checking or adjusting standing h ight.*

Checking: *NOTE - Normalize position of air springs by working the bumper up and down with a car door open, permitting car to assume its normal standing h ight.*

Front of Car - Measure distance from top of left lower control arm to center of the outer lower rivet on front of frame. This measurement should be 3 5/8" ± 1/16". If not within specifications, adjust as outlined below.

Rear of Car - Measure distance from top of rear axle housing to underside of frame at a point directly above the axle housing. This measurement should be 4 13/16" ± 1/16". *(CAUTION - The rear standing height must be within 1/8" on both sides of car).* If not within specifications, adjust as outlined below.

Adjusting: **Front of Car** - Loosen adjusting nut on leveling valve adjusting link at connection on lower control arm. Raise or lower adjusting link until measurement between left lower control arm and center of rivet is 3 5/8" ± 1/16". Allow sufficient time for leveling action to take place, then tighten adjusting nuts and recheck measurement. Check standing height on right side. If measurement varies more than 1/4", check and adjust rear standing height.

Rear of Car - Loosen adjusting nuts on leveling valve adjusting link at connection on lower control link. Raise or lower adjusting link until measurement between top of axle housing and underside of frame is 4 13/16" ± 1/16" on both sides of car. Allow sufficient time for leveling action to take place, then tighten adjusting

CONTINUED ON NEXT PAGE

CADILLAC ELDORADO BROUGHAM (C ntinu d)

nuts and recheck measurement. Recheck front standing height and readjust if necessary.

OVERHAUL

►*REAR UPPER CONTROL YOKE PRODUCTION CHANGE:* The spherical joint used on early production models has been replaced with a rubber bushing on later cars. The grease fitting formerly used with the spherical joint has been replaced with a threaded plug. Under no circumstances should the plug be replaced with a grease fitting on cars with rubber type bushings.

►*AIR SUSPENSION TUBING NUT TIGHTENING CAUTION:* Overtightening of the tubing nuts will damage the "0" ring seal, causing an air leak. Nuts should be tightened to 5-10 ft. lbs. for proper seating.

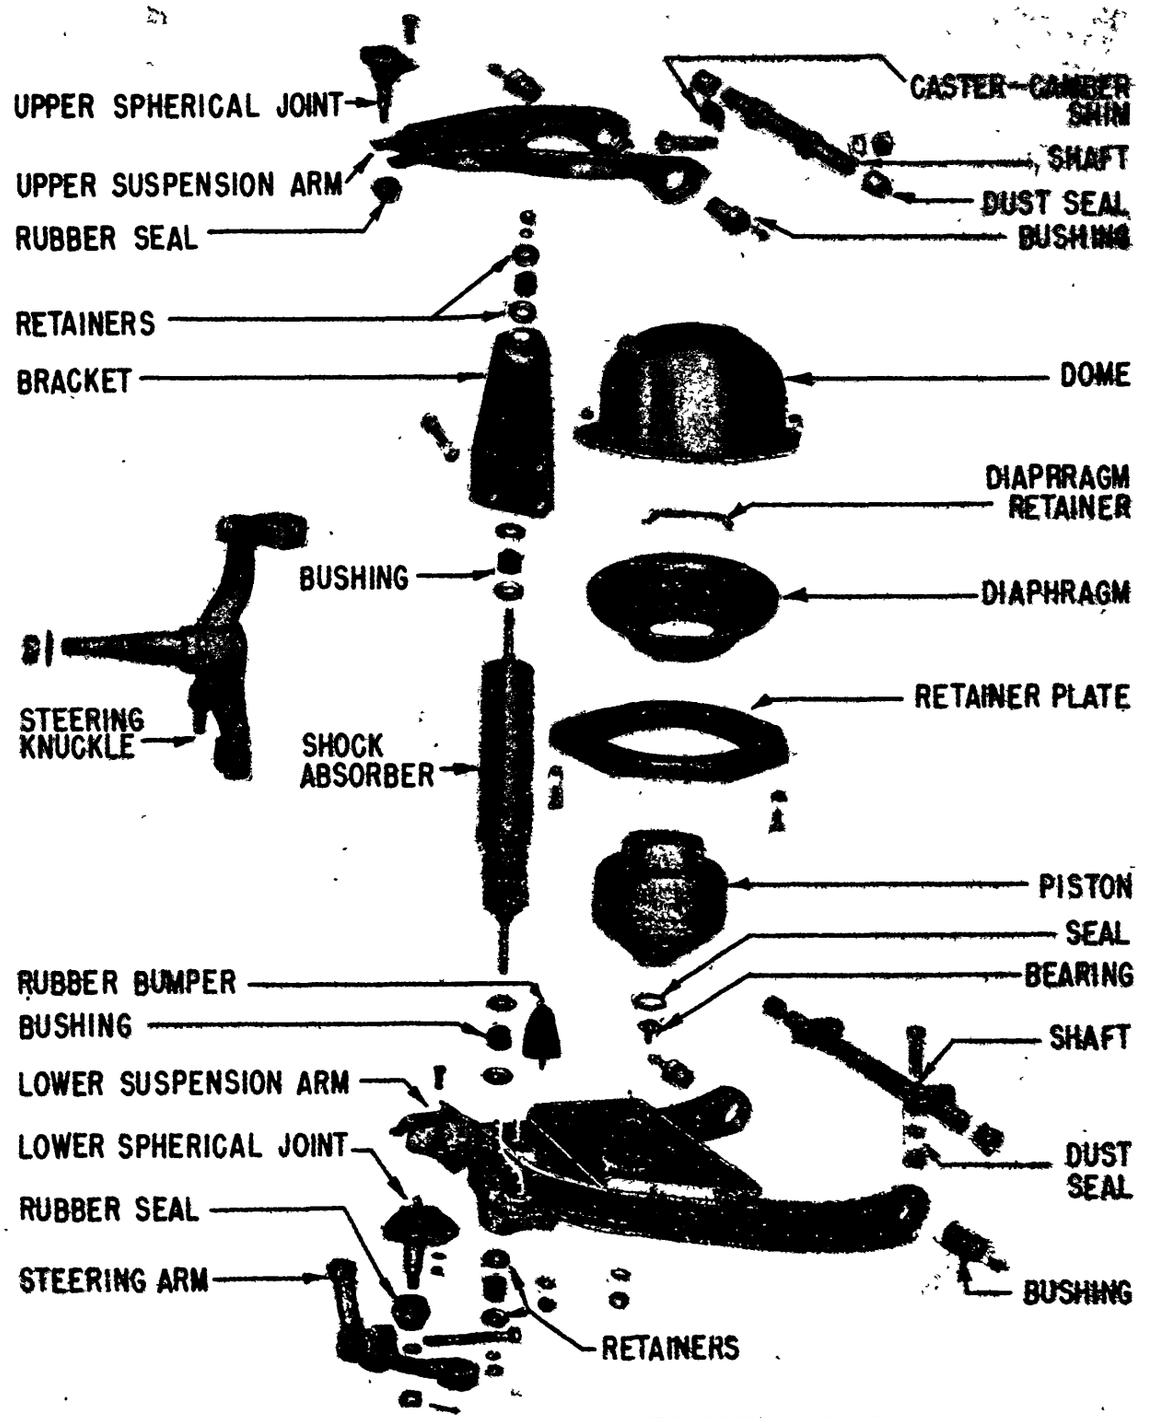
►*AIR SUSPENSION TUBING NUT FITTING CAUTION:* Whenever any air line fitting is disconnected, the "0" ring seal, Part No. 1467287, should be replaced. After tightening, each fitting should be checked for leakage

►*RAISING REAR OF CAR CAUTION: Never raise rear end of car with rear shock absorbers disconnected as it is possible to rais rear nd off its suspension and result in s paration of r ar spring assemblies.*

►*SERVICING CAUTION: Do not open any door or turn ignition on wh n any wh el of car is off the ground.*

FRONT SHOCK ABSORBER: Removal - Raise front of car and place jack stands under lower control arms. Turn wheel for access to shock absorber and remove shock upper retaining nut, retainer, and rubber grommet at frame tower mounting bracket *(NOTE* - Upper stem is square at top so it may be held from turning). Remove shock lower retaining nut, lockwasher, retainer, and rubber grommet at mounting bracket and remove shock. **Installati n:** Reverse removal procedure.

SPHERICAL JOINTS: Rem val, Checking & Installation - Same as for conventional type suspension. *See "Cadillac Front Suspension".*



REAR SHOCK ABSORBER: Removal - Raise rear of car and place jack stands under rear axle housing. Remove upper and lower retaining nuts and lockwashers and remove shock. *CAUTION - Under no circumstances should rear of car be raised in such a manner that rear suspension is in rebound position with shocks disconnected* **Installati n:** Reverse removal procedure.

UPPER CONTROL ARM: Removal - Disconnect battery ground strap. Raise front of car and place jack stands under lower control arms, and remove wheel. Remove cotter pin and nut from spherical joint stud. Strike steering knuckle with a hammer in area of spherical joint to break joint loose. Remove mounting bolts at mounting shaft and remove upper suspension arm with shaft.

Disass mbly & R ass mbly: Same as conventional type. *S e "Cadillac Front Suspension".*

Installation: Install arm in position on frame mounting bracket and tighten bolts to 130-140 ft. lbs. Use original caster and camber shims until alignment checked. Position spherical joint stud in steering knuckle hole, install nut and tighten to 50-60 ft. lbs. Install wheel and connect ground strap to battery.

CONTINUED ON NEXT PAGE

CADILLAC ELDORAD BR UGHAM FRONT SUSPENSION ASSEMBLY

CADILLAC ELDORADO BROUGHAM (C ntinu d)

LOWER CONTROL ARM: Removal - Raise front of car and place jack stands under frame side rails. Remove wheel. Disconnect stabilizer linkage from lower control arm. Disconnect leveling valve adjusting link at lower control arm and pull down on leveling valve control arm to exhaust air from front springs (battery must be connected and a door open). Disconnect battery ground strap, close all doors and remove air piston bearing retainer nut at lower suspension arm. Disconnect air line and remove Schrader valve from front air dome, using Valve Core Remover and Installer Tool J-6888. Disconnect shock absorber at lower control arm and remove lower spherical joint cotter pin and nut. Strike steering arm in area of joint to break it loose, then remove four shaft mounting bolts at frame front crossmember and remove lower control arm.

Disassembly & Reassembly: Same as conventional type. *See "Cadillac Front Suspension".*

Installation: Install mounting shaft on frame crossmember and tighten bolts to 60-70 ft. lbs. Guide spherical joint stud into steering knuckle and install nut. Tighten to 50-60 ft. lbs. and install cotter pin. Connect shock absorber at lower control arm. Install Schrader valve and connect air line in front dome. Install air spring piston bearing retainer nut at bottom of lower control arm Connect leveling valve adjusting link and stabilizer link at lower control arm. Connect battery ground strap and open car door. Install wheel, remove jack stands and lower front end of car. Replenish air supply in accumulator tank through Schrader valve. Check air line fitting on front dome for air leaks by using a soapy water solution. Check standing height and adjust as necessary (see above). Check wheel alignment.

STEERING ARM: Removal & Installation - Same as conventional type suspension. *See "Cadillac Front Suspension".*

REAR WHEEL & BRAKE DRUM: Removal - Raise rear of car and place jack stands under rear axle housing. Place jack under rear bumper on side that wheel is to be removed and raise car sufficiently to remove wheel. *(CAUTION - Do not disconnect rear shock absorber for removal of rear wheel).* Remove brake drum.

Installation: Reverse removal procedure.

AIR COMPRESSOR: *NOTE - If air compressor defective, replace it with a new unit. Do not attempt repairs other than replacement of pressure switch, diaphragm, relay, or oil inlet fitting.*

R moval - Disconnect battery ground strap and exhaust air in accumulator tank at Schrader valve. Disconnect oil inlet and return lines at compressor. Disconnect air cleaner hose at inlet side of compressor. Disconnect harness lead (black) at relay on compressor. Remove two bolts securing compressor to mounting bracket on top of generator and remove compressor.

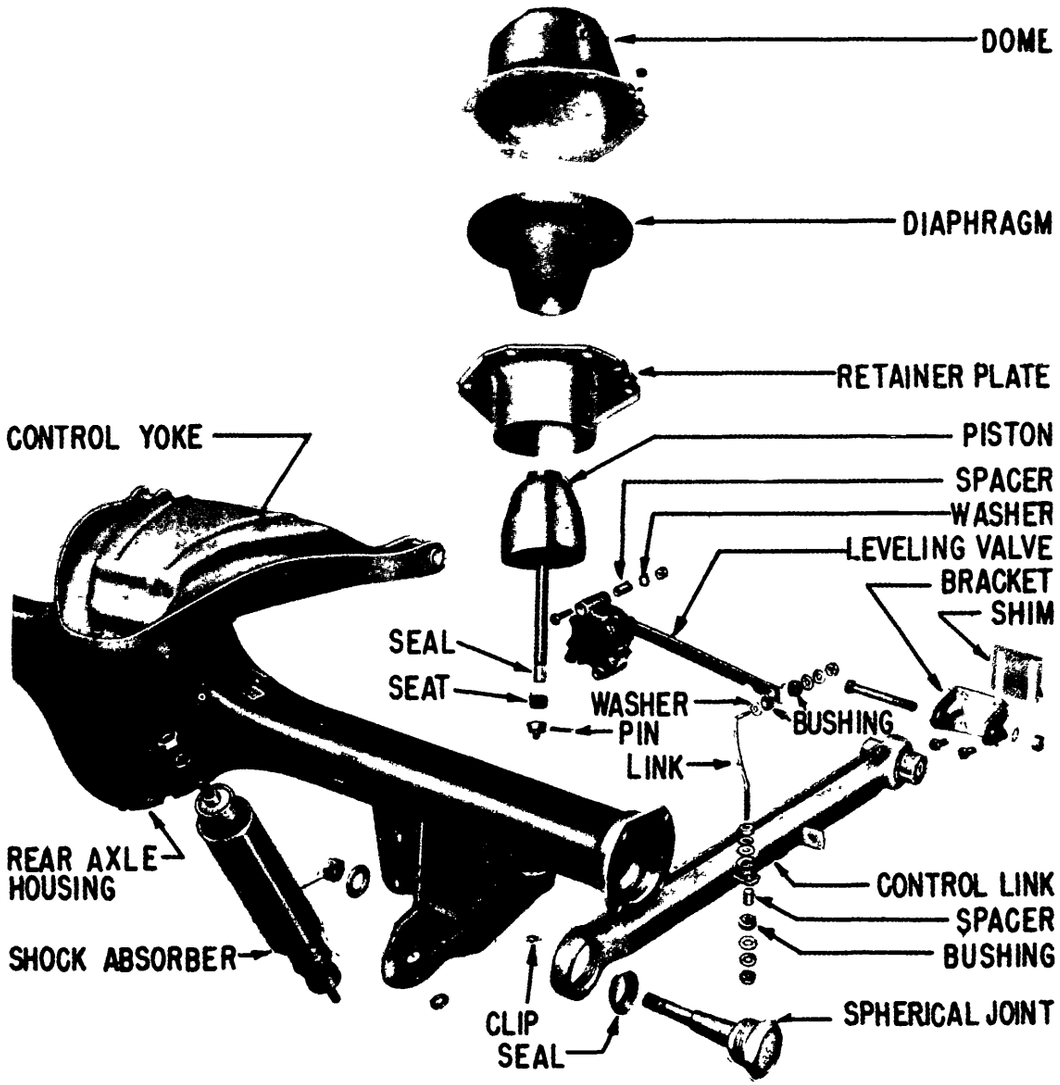
Installation: Reverse removal procedure using a new "0" ring seal at accumulator tank air line. Replenish air supply in accumulator tank through Schrader valve.

AIR COMPRESSOR RELAY: Removal - Disconnect motor lead (black) at relay, and three pressure switch leads (green, white, and pink), at relay. Disconnect harness lead (black) at relay. Remove relay.

Installati n: Reverse removal procedure.

AIR COMPRESSOR PRESSURE SWITCH: Removal - Disconnect three pressure switch leads (green, white, and pink) at relay. Remove two screws securing pressure switch cover to mounting on air compressor head and remove switch cover. Remove four screws securing pressure switch assembly to air compressor head and remove switch assembly. Remove rubber diaphragm from air compressor head.

Installation: Reverse removal procedure, making certain that rubber diaphragm is installed with raised side facing pressure switch plunger.



AIR COMPRESSOR FILTER: *NOTE - A pourex filter in oil inlet fitting should be cleaned when filter changed.*

Removal: With engine **not** running, remove oil inlet line at top of air compressor and remove fitting *(NOTE - The filter is an integral part of fitting and should not be removed).*

Cleaning: Soak oil inlet fitting in grease dissolving solvent and wash thoroughly. Blow air through fitting with air hose and wipe dry.

Installation: Install oil inlet fitting on compressor and

CONTINUED ON NEXT PAGE

CADILLAC EL DORADO BROUGHAM REAR SUSPENSION ASSEMBLY

CADILLAC ELDORADO BROUGHAM (Continued)

connect inlet line. Run engine and compressor to check for oil leakage at fitting.

ACCUMULATOR TANK: Removal - Disconnect battery ground strap and remove radiator grille. Release air pressure in accumulator tank by opening pet cock at lower left side of tank. Disconnect two air line fittings at top of tank. Disconnect electrical lead on pressure switch at bottom left side of tank. Remove two accumulator tank attaching bolts from mounting brackets on each side of air conditioning condenser, and remove tank through grille opening, using care not to damage pressure switch.

Installation: *(NOTE - If new tank is being installed, check for air leakage before installation).* Reverse removal procedure using new "0" ring seals at ends of accumulator tank air lines. Replenish air supply in tank through Schrader valve. Test all fittings for leakage by using a soapy solution. Connect battery ground strap.

ACCUMULATOR TANK PRESSURE SWITCH: Removal - Disconnect battery ground strap and release air in tank by opening pet cock at lower left side of tank. Disconnect electrical lead at pressure switch and unscrew pressure switch from tank.

Installation: Apply permatex to bolt threads at bottom of pressure switch and install switch on tank. Connect electrical lead on switch. Replenish air supply in accumulator tank through Schrader valve. Check for air leakage using a soapy solution, then connect battery ground strap.

CONTROL SOLENOID: Removal - Disconnect battery ground strap, then raise front of car and place jack stands at outer ends of lower control arms. Exhaust air from accumulator tank at Schrader valve. Disconnect accumulator tank air line at top left side of control solenoid. Disconnect front and rear air spring high pressure and exhaust lines from control solenoid *(NOTE* - When exhaust lines are disconnected, front of car may lower slightly). Disconnect two electrical leads at relay on right front fender dust shield. Remove screws securing control solenoid to supporting bracket and remove solenoid.

Installation: Reverse removal procedure, using new "0" ring seals at ends of all air lines.

CONTROL SOLENOID FILTERS: *NOTE* - Three pourex filters, located in the high pressure air line at top left side of unit and in the two exhaust line fittings at lower right front and bottom of unit, are used to prevent foreign particles in air lines. These filters should be cleaned at six-month intervals (more frequently in sandy or desert areas).

Removal: Disconnect battery ground strap. Raise front of car and place jack stands at outer ends of lower control arms. Exhaust air from accumulator tank through Schrader valve. Disconnect high pressure line at top left side of control solenoid. Disconnect exhaust lines at lower right front and bottom of control solenoid. Remove air line fittings from control solenoid where air lines were previously disconnected and lift out filters.

Cleaning: Clean filters in suitable solvent and blow dry with air.

Installation: Reverse removal procedure using new "0" ring seals at ends of air lines. Check for leakage at all air line fittings using a soapy solution.

RESTRICTION CHECK "TEE" VALVE: Removal - Disconnect battery ground strap. Raise front of car and place jack stands at outer ends of lower control arms. Disconnect leveling valve air line at top of check valve *(NOTE* - All air will exhaust from front air springs and front end of car will settle into full compression in approximately five minutes). Wait for front end to lower, then disconnect front spring air line at check valve. Remove screw securing check valve to front frame member and remove check valve.

Installation: Reverse removal procedure using new "0" ring seals on ends of all lines. Replenish air supply in accumulator tank. Check for air leakage at all fittings using a soapy solution.

FRONT LEVELING VALVE: Removal - Raise front of car and open any door. Disconnect adjusting link at leveling valve control arm and pull down on control arm to exhaust air from front springs. Disconnect three air lines from leveling valve *(NOTE* - A slight discharge of air might take place). Remove two bolts retaining leveling valve to support bracket and remove leveling valve.

Installation: Reverse removal procedure using new "0" ring seals at ends of all lines. Lower car and leave any door open. Replenish air supply in accumulator tank. Check air line connections for leakage using a soapy solution. Check and adjust standing height (see above).

REAR LEVELING VALVE: Removal - Disconnect battery ground strap. Raise rear of car and place jack stands under rear frame side rails. Disconnect air line at rear spring air dome. Disconnect adjusting link at leveling valve control arm. Disconnect three air lines from leveling valve *(NOTE* - A slight discharge of air may take place). Remove two bolts retaining leveling valve to support bracket and remove valve. *(NOTE* - On right side only, remove two valve-to-support bracket spacers).

Installation: Reverse removal procedure, making sure to replace leveling valve-to-support bracket spacers on right side. Use a new "0" ring seal at ends of all air lines and check for air leakage. Check and adjust standing height (see above).

FRONT AIR SPRING (RIGHT OR LEFT): Removal - Remove lower control arm (see above). Remove three mounting bolts securing air spring assembly to front frame member and remove spring assembly.

Disassembly: Remove four attaching bolts securing retainer plate to dome, and separate retainer plate from dome. Remove "0" ring seal and phenolic resin bearing from bottom of piston. Remove piston and diaphragm from air dome. Remove diaphragm retainer from piston and lift diaphragm off piston.

Reassembly: Wipe inner surface of air dome and outer surface of piston with a clean cloth. Make sure that diaphragm contact areas are free from foreign particles or sharp edges. Apply DC-4 Silicone compound to outer edges of upper and lower diaphragm lips. Install diaphragm on piston and replace diaphragm retainer. Install piston and diaphragm assembly in air dome in as straight a position as possible, using care not to distort or bend out the upper lip of diaphragm. Install retainer plate on air dome and secure with four attaching bolts. Install Schrader valve core in air dome. Apply a liberal amount of heavy front wheel bearing grease in cavity at base of piston and install a new phenolic resin bushing and "0" ring seal.

Leak Test - Using a vise, install front air spring assembly in Holding Tool, J-6885, making sure that tool is securely attached as it will be subjected to extreme pressure. Insert Pilot Adapter, Tool J-6885-5, in hole at bottom of holding tool. Install Air Dome Valve Adapter, Tool J-6881, in air fitting in dome, making sure that fitting contains valve core. Introduce air slowly into air dome, guiding piston retainer bolt so that it seats properly in pilot adapter. Continue to add air until pressure builds up to 80-100 lbs., check air pressure with Pressure Gauge, Tool J-6840, and remove valve adapter tool. Remove complete assembly from vise, submerge in water and check for air leaks. Release all pressure in air dome by removing Schrader valve core. Remove spring from holding tool and install Schrader valve core in air dome.

Installation: Add a small amount of air to the air dome (approximately 5 lbs.) to prevent movement of diaphragm during installation. Reverse removal procedure using a new "0" ring seal at end of front spring line at air dome. Replenish air supply in accumulator tank and check for air leakage. Check and adjust standing height.

REAR AIR SPRING (RIGHT OR LEFT): Removal - Raise rear end of car, with any door open, and place jack stands under rear frame rails. Remove rear wheel *(CAUTION - Do not disconnect either rear shock absorber).* Disconnect adjusting link at leveling valve control arm and pull down on arm to exhaust air from rear spring. Disconnect battery ground strap. Disconnect air line at dome and remove Schrader valve core, using Valve Core Remover & Installer, Tool J-6888. Remove hairpin clip at bottom of piston rod, then push piston rod up and remove rod from socket in axle housing support bracket. Unscrew piston from diaphragm and remove piston assembly. Remove four mounting bolts securing rear air spring assembly to frame mounting bracket, and remove rubber bumper. Remove rear air spring assembly through wheel opening in fender

Disassembly: In the event piston is still attached to diaphragm in air spring, unscrew and remove it. Remove four attaching bolts securing retainer plate to dome and separate dome from plate. Remove rubber bumper. Remove diaphragm from air dome and tapered pin from lower end of piston rod. Remove seat and rubber seal.

Reassembly: Wipe inner surface of air dome with a clean cloth and make sure that diaphragm contact area is free from foreign particles or sharp edges. Apply DC-4 Silicone compound to outer edge of diaphragm lip, then install diaphragm in air dome in as straight a position as possible, using care not to distort or bend out the lip of diaphragm. Install retaining plate on air dome and secure with four attaching bolts. Install valve core in air dome. Install rubber seal on piston rod. Fill piston rod seat with heavy front wheel bearing grease, then install seat on rod and secure with tapered pin. Attach

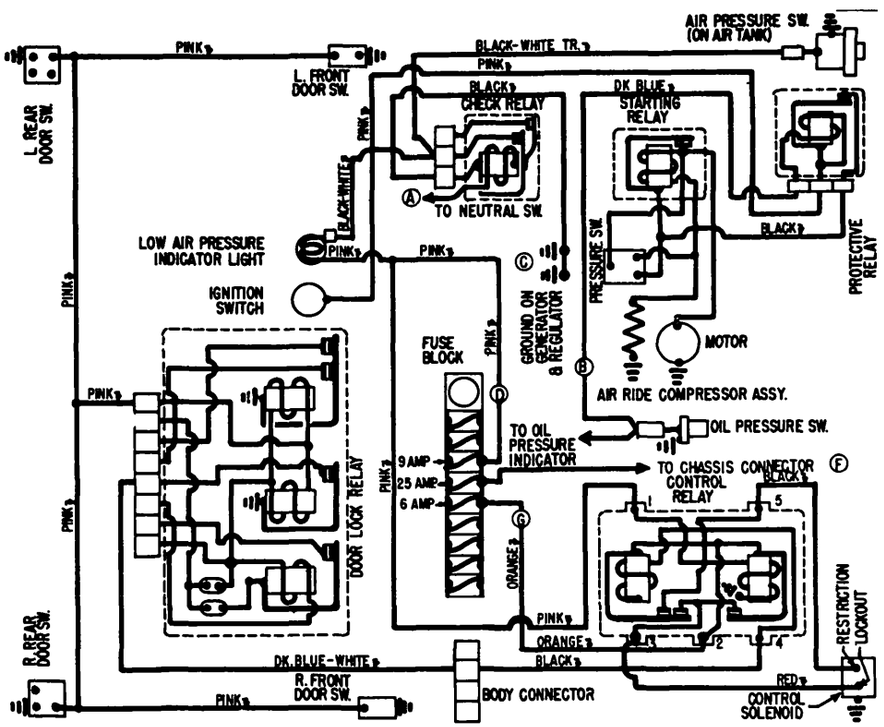
CONTINUED ON NEXT PAGE

CADILLAC ELDORADO BROUGHAM (C ntinu d)

piston to diaphragm, **tightening as much as possible by hand only.**

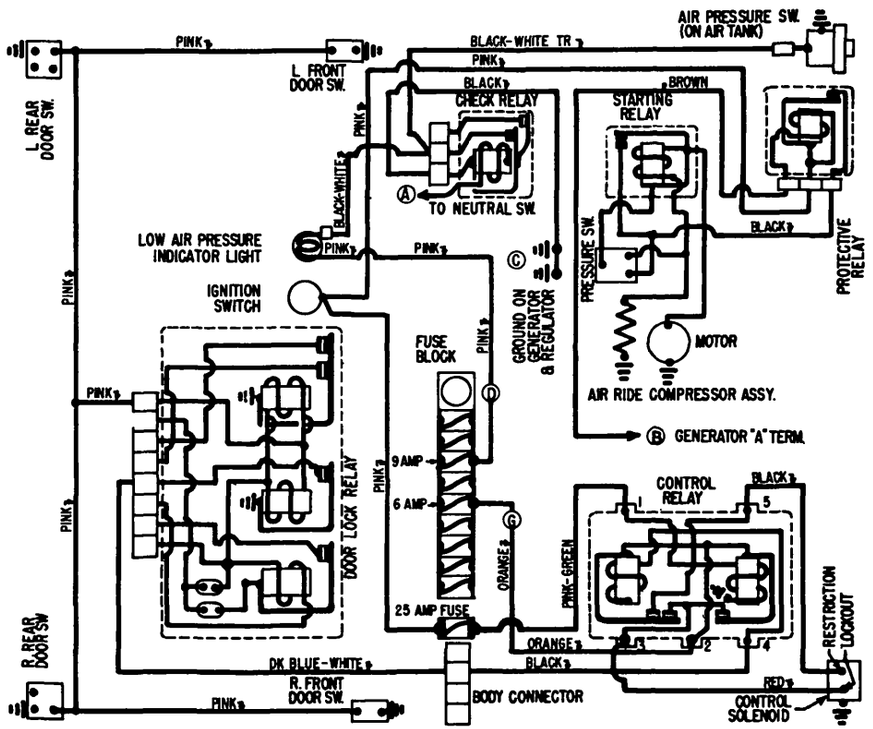
Leak Test - *See "Front Air Spring (Right or Left)" above.*

Installation: Add a small amount of air to air dome (approximately 5 lbs.) to prevent movement of diaphragm during installation. Reverse removal procedure, installing rear air spring as a complete assembly with piston securely attached to diaphragm. Use a new "0" ring seal at end of air line at air dome. Replenish air supply in accumulator tank and check for air leakage. Check and adjust standing height (see above).



REAR UPPER CONTROL YOKE: *NOTE - Early cars are equipped with a spherical joint at rear mounting of yoke. Later cars have a rubber bushing. The lubrication fitting used with the spherical joint is replaced with a threaded plug on later cars having the rubber bushing. Under no circumstance should the plug be removed and replaced with a grease fitting on cars with rubber type bushings.*

R moval: Raise rear of car, with one door open, and place jack stands under rear frame rails. When air pressure is exhausted in springs, remove battery ground strap. Disconnect both rear spring air lines at leveling valves. Center jack under differential housing as a support (do not raise housing). Disconnect rear end of upper control yoke by removing mounting bolts securing yoke to spherical joint or rubber bushing on top of differential housing. Yoke will spring up to its design height position *(CAUTION - Note this position by measurement as control yoke front attaching bolts must be torqued with yoke in this position when yoke is installed).* Remove control yoke front attaching bolts at frame crossmember just forward of rear axle. Remove yoke over top side of differential housing.



Installation: Place control yoke in position and install the two front attaching bolts (do not tighten bolts). Position yoke to same position as noted by measurement at removal and tighten front attaching bolts to 85-95 ft. lbs. Pull down on yoke and attach rear end to spherical joint or rubber bushing. Tighten bolts to 35-40 ft. lbs. Connect both rear spring air lines at leveling valves, using new "0" ring seals at ends of lines. Lower car, open any door, connect battery, and replenish air supply in accumulator tank. Check all air line fittings for leakage. Check and adjust standing height (see above).

REAR LOWER CONTROL LINK (RIGHT OR LEFT): Removal - Raise rear of car with one door open. Place jack stands under rear frame rails, and remove rear wheel. *(NOTE* - Rear end of control link is not in rebound position, 5" below design height). When air in rear springs is exhausted, disconnect battery ground strap. Center jack under differential housing to support it (do not raise housing). Disconnect rear spring air line at leveling valve. Loosen parking brake equalizer locknut and disconnect cable. Remove spring clip retaining parking brake cable at No. 4 body bracket. Draw parking brake cable through grommet in bracket on outer side of control link. Disconnect leveling valve adjusting link at control link. Measure distance from ground level to centerline of spherical joint at rear of control link. **Add 5 inches to this measurement** to compensate for rebound distance, and note total. When control link is installed, front attaching bolt must be torqued with control link at design height. Remove attaching bolt from front end of control link at body mounting bracket. Disconnect spherical joint at rear end of control link under rear axle housing and remove control link.

Installation: Install front end of control link first. Replace attaching bolt but do not tighten. Position control link at design height as determined at removal, and tighten front attaching bolt to 85-95 ft. lbs. Pull down on control link and attach rear end to spherical joint under rear axle housing. Tighten stud to 70-80 ft. lbs. Complete installation by reversing removal procedure, using new "0" ring seals in all air lines. Lower car, open door, connect battery, and replenish air supply in accumulator tank. Check for air leakage at all fittings. Check and adjust standing height (see above)

1957 CADILLAC ELDORADO BROUGHAM AIR SUSPENSION WIRING DIAGRAM

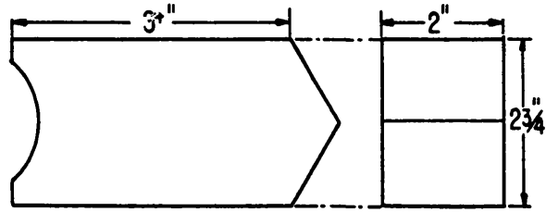
1958 CADILLAC ELDORADO BROUGHAM AIR SUSPENSION WIRING DIAGRAM

CHEVROLET LEVEL AIR SUSPENSION

Ch vr l t (1958-59)

►CHANGES, CAUTIONS, CORRECTIONS

►*SERVICE CAUTIONS:* Before working under the car, jacking it up, or raising it on a hoist, the following precautions must be taken to prevent personal injury or damage to the car.



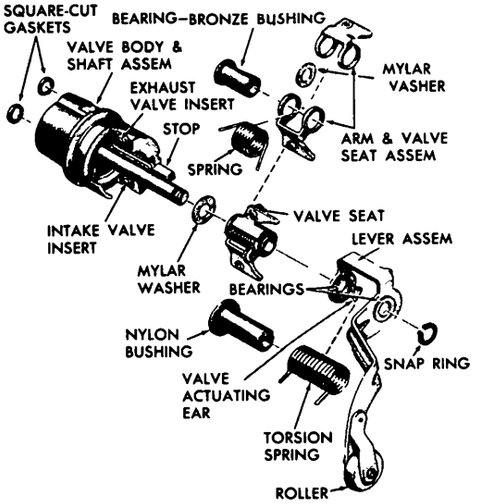
Raising Car (On a Jack) - With car at its normal operating height, close manual shutoff valve located on top of junction block at left side of engine adjacent to the accumulator tank. *CAUTION - Be sure valve is opened after removing from jack, as serious damage can result.*

Raising Ca (On a H ist) - When raising a car on a frame contact type hoist or on any hoist that does not support the car under all four wheels, the manual shutoff valve must be closed. *S e "Raising Car (On a Jack)" above.*

W rking Under Th Car - Always place jack stands under an air suspension car before using a creeper as a precaution in case air should be exhausted from system.

►*TOWING THE CAR:* **Air Suspension System Operating** Run engine and compressor long enough to fill system, then close manual shutoff valve. Raise car and proceed in the normal manner.

Air Suspension System Operating (Compressor Not Working) Fill system from a tow truck equipped with a compressor or storage tank. Remove cap from Schrader valve on the high pressure accumulator and apply pressure until system inflates to normal. Close manual shutoff valve on junction block and proceed in the normal manner.

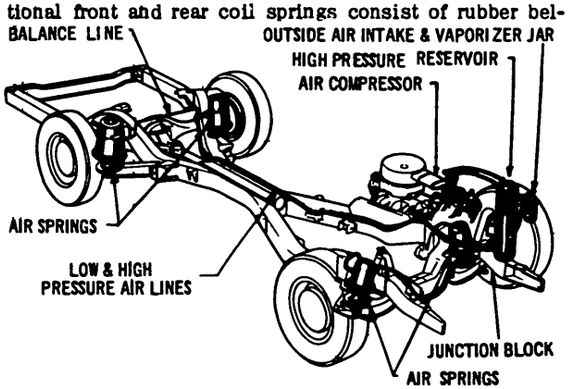


CHEVR LET REAR TOWING BLOCKS

Air Suspensi n System N t Operating: *NOTE* - With air pressure completely exhausted from system the body-frame assembly will not have more than 2-4" ground clearance. The car may be towed on a smooth road at a speed not exceeding 10 MPH. If necessary to move car over a rough or hilly road, proceed as follows:

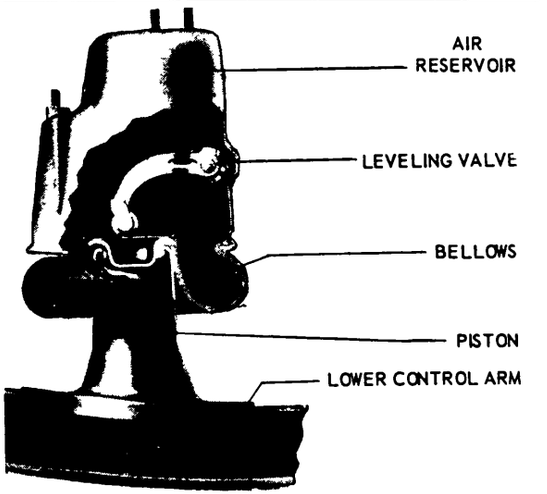
Fr nt End Rais d (Meth d No. 1) - Attach tow truck lifting chains to appropriate locations on frame or crossmember. Raise slightly to allow removal of front wheels, then lower chains slightly to give adequate clearance for towing. DO NOT tow for great distances or at speeds over 10-15 MPH. Check periodically to make sure chains have not slipped or that ground clearance has not changed due to type of load, shifting loads, etc.

Fr nt End Raised (Meth d N . 2) - Make two blocks, (see illustration), from a good hardwood that will not break or crack. Raise frame of car with a jack and place a block between rear axle housing and frame. Holes drilled at each end of block should be used to attach



CHEVROLET LEVELING VALVE ASSEMBLY

block to frame and axle housing. Attach chains to front cross member or frame and tow car in the usual manner, but at a reduced speed.



Rear End Raised - Install a cable loop around both frame side members at a point 5" forward or rear edge of frame to provide means of lifting rear of car. Raise car at front so that inner ends of lower control arms are pointing upward a slight amount, then using a piece of 2" x 6" board (channel or angle iron), securely attach under the crossmember and to outer portions of lower control arms. Use suitable "C" clamps, chain, or steel cable to attach this piece to control arms and crossmember. Lower car to ground and tow in the usual manner at a reduced speed.

►*1959 LOW PRESSURE BLOW-OFF VALVE PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* A new valve, Part No. 3769872 is being used in production and for service replacement to reduce blow-off pressure from 20—25 lbs. to 5—10 lbs. The new valve will reduce compressor drive belt squeal and increase durability of compressor belt.

DESCRIPTION: Air springs used to replace the conventional front and rear coil springs consist of rubber bellows and metal reservoir assemblies. These units are attached to the frame crossmember and lower suspension arms (front of car) and to frame side rail and lower control arms (rear of car). Normal riding height is maintained automatically by air pressure controlled by the height control valve in each of the front springs and in the left rear spring. Other basic components of the system operate as follows:

CHEVR LET AIR SUSPENSI N SYSTEM

CHEVROLET FRONT AIR SPRING ASSY.

Air Compressor: Single stage, single cylinder reciprocating type, driven by a belt from engine fan assembly. Compressor is lubricated by oil from the engine pressure oiling system which is introduced through a connection on the compressor bearing housing. Drilled passages in the compressor crankshaft provide lubrication to connecting rod and crankshaft bearings and to cylinder walls. Oil is returned to the engine crankcase by a line from the compressor sump.

High Pressure Accumulator Tank: Mounted in engine compartment on left side of car adjacent to manual shutoff valve. This tank is used to maintain a reserve supply of high pressure air and to trap moisture and oil in the system. A Schrader type valve on accumulator tank permits filling tank with air from an outside source. A drain valve at lower end of tank is provided to drain accumulated oil and water.

Manual Shutoff Valve & Junction Block: This valve is located in the junction block adjacent to accumulator tank in engine compartment and is provided as a means of shutting off low pressure side of system from compressor inlet and the low pressure safety valve. It is used for special purposes such as shipping, towing, using a bumper jack, or raising the car on any type hoist that does not support the car under all four wheels. Also included in the junction block is the high pressure safety valve, low pressure safety valve, and passages connecting accumulator tank, compressor, and leveling valves.

CONTINUED ON NEXT PAGE

CHEVROLET LEVEL AIR SUSPENSION (C ntinu d)

Fr nt Height Control (Leveling) Valves: Each of the front air spring assemblies contain a height control (leveling) valve mounted in the metal portion of the assembly. The valve is actuated by a lever assembly contacting the center of the air spring bellows. Vertical movement of the car causes the valve to admit or exhaust air from bellows assembly in relation to car loading requirements, and to maintain car in a level position.

R ar Height Control (Leveling) Valve: This valve is located in the left rear air spring assembly and operates in the same manner as for front height control valves. An intake and exhaust line interconnects left and right rear air springs and the rear height control valve controls pressure in both springs.

Vaporizer Jar: Located adjacent to accumulator tank in engine compartment. Make-up air drawn by the compressor from outside the system passes over alcohol in the bottle and prevents icing conditions in air suspension system during cold weather.

ADJUSTMENTS

ADJUSTMENTS: Air Compressor Drive Belt - Loosen compressor-to-bracket mounting bolts and nuts and move compressor until there ¼" deflection with a 15 lb. pull between fan and compressor. Hold compressor in position and tighten attaching nuts.

Fr nt End Alignment: Same as for cars with conventional coil springs. *See "Front Suspension" on Car Model page.*

DRAINING ACCUMULATOR TANK: Every 1000 miles, open drain valve located at bottom of tank and drain out accumulated water and oil *NOTE - This drain period supersedes previous recommended drain period of 5000 miles*

VAPORIZER JAR: For cold weather operation, fill jar half full with grain, wood, denatured, or methyl alcohol Every 1000 miles, when accumulator tank is drained, it will be necessary to bring the alcohol level in vaporizer jar to the one-half full mark *NOTE - It is not necessary to add alcohol to vaporizer jar between accumulator drain tank drain periods*

FRONT LEVELING VALVE EXTERNAL ADJUSTMENT (1959 MODELS): *NOTE - Front leveling valves have been revised to provide an external adjustment, permitting and "out of plane" car to be correct without removing valve* To adjust valve, loosen valve retaining nut and rotate the valve as follows **Left Front Valve** - Counterclockwise rotation of valve raises corner of car Clockwise rotation lowers it **Right Front Valve** - Clockwise rotation of valve raises corner of car Counterclockwise rotation lowers it After tightening nut, check for leakage around nut

REMOVAL & INSTALLATION

LOWER CONTROL ARM: Removal & Installation - Remove air spring (see below), then remove lower control arm in same manner as for coil spring cars *(see "Chevrolet Front Suspension")* Install by reversing removal procedure

UPPER CONTROL ARM: R m val & Installati n - Remove and install upper control arm in same manner as for coil spring cars *(s "Ch vrol t Front Suspensi n")* Install by reversing removal procedure

AIR COMPRESSOR: R m val - Disconnect air and oil lines at compressor and remove the four compressor to mounting bracket bolts, drive belt and compressor.

Installation: Clean oil supply line to compressor and if possible run engine for a few seconds to be certain oil supply to compressor is flowing freely. *(CAUTION - Extreme care must be used during this operation. Make sure engine crankcase is full and operate engine no longer than necessary to check oil flow).* Clean oil return line to engine crankcase, then install compressor by reversing removal procedure. *NOTE* - To maintain proper oil level in compressor, it is important that the oil return hose must not be higher than the opening into compressor.

LEVELING VALVE (FRONT OR REAR): Removal - Completely inflate air suspension system, then block up front control arms so there is more than 6¼" between base of rubber bumper and pad on frame that bumper contacts. On rear end, install spacer blocks (same as used for towing, see illustration). Bleed all air from system and disconnect air lines at leveling valve by slowly loosening the two (three on left rear valve) tubing fitting locknuts. Using a 1 9/16" deep socket (with an adapter for ½" drive) remove locknut on leveling valve at air bellows. Carefully withdraw leveling valve from air bellows by hand. Valves withdraw easily by rotating valve body slightly to allow for offset angle of lever. DO NOT force or use tool to remove.

Installation: *(NOTE* - Each leveling valve has the part number stamped on lever assembly and each are color coded as follows for further identification **Left Front** - Orange (Part No. 5539293), **Right Front** - Blue (Part No. 5539294), **Left Rear** - Gold (Part No. 5539295). Place new "0" ring gasket over lever assembly and slide into recess against shoulder of valve body (do not stretch "0" ring). Carefully insert valve into neck of air reservoir housing so that neck detent engages locating slot of valve body. *(CAUTION* - Spacing blocks must still be in place during installation of valves). With shoulder of valve body pressed firmly against neck, tighten valve retaining nut to 12-14 ft. lbs. Install new "0" ring seals in fittings and install air lines to valve. Tighten locknuts to 5-7 ft. lbs.

FRONT AIR SPRINGS: Removal - Place car on frame contact hoist or support frame with jack stands so front wheels swing down freely. Exhaust all air from suspension system (open drain valve at bottom of accumulator tank). Disconnect stabilizer bar from frame and control arm, then remove shock absorber lower mounting. Remove bolts attaching control arm cross shaft to frame and swing control arm down and away from crossmember. Remove leveling valve (see above). Remove two locknuts on top of frame (directly above air spring bellows assembly) and withdraw assembly from frame. Push bellows near the sealing lip using a hammer handle, until lip is approximately half way up into reservoir. This will place bellows almost crosswise in reservoir and then it can easily be rolled out. *NOTE* - The rubber bellows is serviced separately from reservoir. DO NOT reuse an old rubber bellows after removal as this operation will destroy rubber material and will not allow it to seat properly on sealing lip of reservoir.

Installation: Clean sealing surface of reservoir thoroughly, using steel wool (in a circular motion). Blow clean with air. Coat sealing lip of reservoir and bellows with a rubber lubricant, then using a length of common clothes line or rope (approx. ¼" diameter), wrap it once around rubber bellows above lip. Tie rope with a simple knot. Tuck "bulge" part of bellows, at red dot, under the sealing lip, then insert it into reservoir with red dot toward pivot (forward) end of suspension arm. Untie rope. While pushing sealing lip into reservoir, the seal must be pulled into position and against the retaining ring by a pulling manipulation on the rope. Set air spring bellows in place on suspension arm, then working through drilled hole in floor pan, and under floor pan, secure with four attaching locknuts. Plug drilled hole with plug, Part No. 1178365. Install new "0" ring seals on valve and insert leveling air spring assembly (see "Leveling Valve Installation" above). Check for leaks after car has been removed from hoist or jack.

REAR AIR SPRINGS: Removal - On 1958 Models, remove rear seat, seat back, rear floor covering and partition between trunk compartment and rear seat back Drill 1½" holes on each side of car at a point 4 5/32" from wheel housing and 12 15/32" forward of rear edge of raised portion of trunk compartment (Pass Cars) *NOTE - On 1958 Station Wag ns, there are dimples in production floor pans indicating locations to be drilled On 1959 Models, it is not necessary to drill floor pan* To remove bellows, inflate system and place wooden spacer blocks *(use Rear Towing Blocks' see illustration above),* between body mount and floor pan *NOTE* - If system cannot be inflated, jack up rear of car and install blocks Place car on a hoist (if frame contact hoist used, no spacer blocks will be required except to assist car onto hoist), then exhaust all air from system Remove air lines and 1 9/16" retaining locknut then remove leveling valve On 1958 Models work through drilled holes in floor pan and remove locknuts attaching bellows assembly to frame On 1959 Models, remove four body bolts and rear bumper bolts at corner being worked on Carefully pry up body and insert a 2" block between body mount and floor pan, then remove two locknuts on top of reservoir On all models, remove bellows assembly

Installation: Reverse removal procedures and note the instructions for installation of "Front Air Springs" above

HIGH PRESSURE ACCUMULATOR: R m val - Exhaust all air from accumulator, remove bolts holding horn relay and regulator to bracket on top of tank. Remove tank to junction block air passage line, and remove compressor discharge line and check valves. Remove two upper attaching bolts, washers, spacers, grommets, washers and nut. Remove lower attaching bolt and withdraw tank from under hood.

Installation: Reverse removal procedure and note the following Install new "0" ring seals in all fittings. Tighten attaching bolts to 7-9 ft. lbs.

JUNCTION BLOCK: Removal - Exhaust all air from high pressure accumulator, then remove seven air pressure lines and one hose from junction block. Discard insert seals. Remove mounting bolts and remove valve.

CONTINUED ON NEXT PAGE

Form 55 A

CHEVROLET LEVEL AIR SUSPENSION (C ntinu d)

Installati n: Reverse removal procedure. *NOTE* - Install new "0" ring seals in junction block.

TROUBLE SHOOTING

Entir Unit Will N t H ld Air: Leakage in system. Compressor not operating properly. Safety valve not operating properly. Schrader valve core loose or leaking. Drain cock leaking or not closed.

Impr p r Acti n At Air Spring Bellows: Broken, bent, or worn leveling valve. Pinched or plugged air pressure line to leveling valve. Plugged outlet on junction block. Ruptured air spring bellows.

Syst m Exhausts Wh n Jacking Up Car or When Placed n a Hoist: Manual shut-off valve open.

Unit Rais s t Full R b und Position: Manual shut-off valve closed with compressor operating.

Will N t Ris T D sign Height With Compressor Operating. Compressor discharge line not connected, or broken. Drain cock at bottom of high pressure accumulator tank open. High pressure accumulator tank to junction block line loose, broken or disconnected. Excessive number of leak points.

Rear Of Car High Or L w, Or One Front Corner High Or L w: Improperly adjusted leveling valve or valves. See "Front Leveling Valve External Adjustment" above. Leveling valve retaining nut tightened excessively. Leveling valve arm bent. Manual shutoff valve closed during car operation. Pinched or plugged air pressure line to leveling valve. Leveling valve not operating properly in freezing climate because of an icing condition in valve.

Car High At Whe ls: Manual shutoff valve closed during car operation. Improperly operating low pressure blow off valve. Leveling valve not operating properly in freezing climate because of an icing condition in valve.

Car S ttl In A Sh rt Tim : Small system leaks. High pressure tank check valve stuck open. Leakage in high pressure relief valve (in junction block). Accumulator drain cock open or leaking. Schrader valve core loose or leaking.

N Build-Up Of Air Pressure: Improperly operating compressor. Complete blockage in compressor outlet line. Large leakage in system. Diffuser on accumulator inlet fitting plugged with carbon. Accumulator drain cock open or leaking Schrader valve core loose or leaking.

Compressor Driv B lt Jumps Off Pulley: Improperly operating low pressure blow off valve. Complete blockage in compressor outlet line. Diffuser on accumulator inlet fitting plugged with carbon. Wrong pulley installed. Misalignment of compressor on its base. Very loose compressor drive belt.

Sl w Build-Up Of Air Pr ssur : Poor compressor efficiency. Restriction in compressor inlet system. Accumulator drain cock open or leaking. Schrader valve core loose or leaking. High altitude.

System Exhausts When Jacking Up Car Or When Placing On Hoist: Manual shutoff valve open.

Noisy Leveling Valve: Leveling valve inlet check valve not operating properly.

Excessive Accumulation Of Water In Accumulator Tank: Leaks in system. High climatic humidity.

Excessive Quantity Of Oil In Fluid Passed From Accumulator Tank: Restriction in compressor inlet system. Improperly operating compressor.

OVERHAUL

AIR COMPRESSOR: *See "Air Suspension Air Compressor".*

►*LEVELING VALVE BODY REPLACEMENT CAUTION:* After reassembly of valve, check endplay of actuating lever on shaft. This endplay should be .005-.015", measured at the snap ring. If endplay is greater, support valve assembly and slowly press shaft into body until endplay is within specifications.

LEVELING VALVES: Disassembly - *(NOTE* - Leveling valves are factory adjusted according to individual parts requirement. Keep parts separate and replace same parts in each valve). Using a small punch or suitable tool, release tension on torsion spring by depressing upper spring tang away from retaining tab on lever assembly. *(CAUTION* - Keep fingers clear of spring tang when releasing spring). Carefully remove lever assembly snap ring with Truarc pliers. Note position of lower spring tang and valve actuating ear of lever assembly in relation to stop of valve body and shaft assembly. Remove lever assembly, torsion spring any nylon bushing from shaft. Press arm and valve seat assemblies away from valve inserts and slide arms, spring mylar washer, and bearing off shaft. Note position of spring and arms before further disassembly. Remove mylar washer located at base of shaft. Remove "0" ring gasket from valve body recess and discard. Remove tube fitting gaskets and discard.

Reassembly: Check all parts for wear or breakage, then clean all parts quickly by dipping each part into solvent and immediately blowing dry. *(CAUTION - Do not use a solvent that is injurious to rubber).* Replace mylar washer on shaft of valve body and shaft assembly, then move it down to seat against valve body. Assemble arm and valve seat assemblies (spring, mylar washers, and bearing) as a unit before placing on shaft. Place this unit on shaft with pointed ends of arms away from valve body. Spread arms at least 180° and press unit down to seat against mylar washer and valve body. Release arms, permitting rubber valve seats to engage valve inserts. Be sure valve seats and and inserts are correctly aligned. Insert nylon bushing into torsion spring and place both between the two bearings of lever assembly, with wide base of bushing nearest valve actuating ear of lever. Place lever, spring and bushing on shaft of valve body. Carefully mount valve body in soft jawed vise with lever arm up *(CAUTION* - Use care not to damage valve body). Locate upper spring tang against retaining tab of lever, then using a small tubing or suitable tool, rotate lower spring tang nearly one full turn counterclockwise against tension and engage tang against valve body stop. Install Truarc snap ring into recess near end of shaft.

Checking Leveling Valve Operation: *NOTE – Use Tool J-7417 consisting of stepped gauges and a mounting fixtures for proper checking of leveling valves.* With leveling valve removed from car, clamp lower flange of mounting fixture in a vise, then slide valve body into large hole in fixture and tighten the thumb screw into keyway on valve body. Install large leveling valve attaching nut removed from the car. Connect an air line to threaded opening of inlet valve. *NOTE – The pipe fittings used for past model Chevrolet spark control lines may be used for the air line connections.* Select the proper gauge for the valve being tested and use the "inlet open" step on gauge to position nylon roller relative to the end of fixture. With gauge held against the roller, apply air to inlet valve. Air should be heard coming through the valve. Check "inlet closed" position in a similar manner. No air should be heard coming through valve. If a valve leak is heard on the "valve closed" position, check rubber valve seat for possible damage. Replace seat if necessary. Recheck valve operation in the checking gauge, and if necessary, carefully adjust valve opening by bending the metal actuating tab on valve seat assembly (in area that contacts valve lever). *NOTE – The small rubber button type seats are easily replaced by pulling them out with needle nose pliers. To replace these seats, set them in place and pull snugly against arm. Be sure that rubber shoulder on rubber seat is fully seated.*

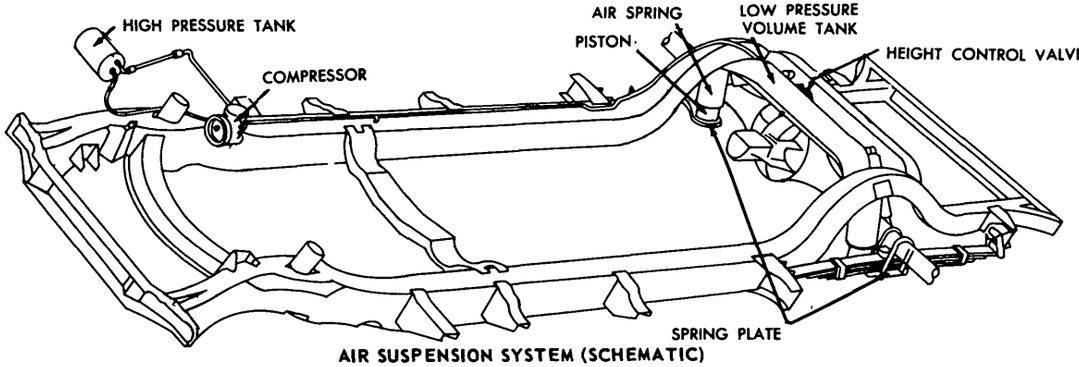
►*LEVELING VALVE LUBRICATION NOTE (After Overhaul):* After each valve is overhauled and assembled, add not more than 2 or 3 drops of SAE 20 oil to each of the following parts: Torsion spring, arm and valve seat spring, lever assembly bearing, arm and valve seat bearing, and lever assembly roller. *DO NOT ov r lubricate.*

JUNCTION BLOCK: *NOTE* - Each individual component (Schrader valve, manual shut-off valve, hose connection or high and low pressure safety valves) can be unscrewed from junction block for replacement or inspection.

FRONT END ADJUSTMENT: *See "Front Suspension" on Car Model pages.*

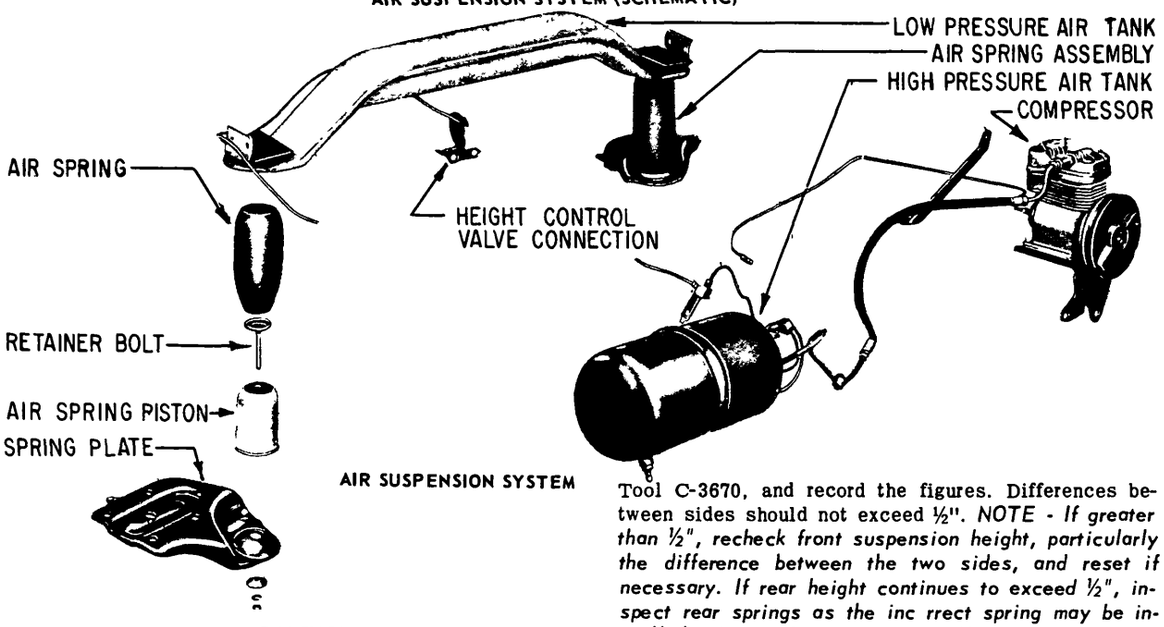
CHRYSLER, DE SOTO, DODGE, PLYMOUTH AIR SUSPENSION

Chrysler, DeSoto, Dodge, Plymouth (1959)



► *1959 COMPRESSOR RATTLE NOISE CORRECTION:* This noise, if caused by excessive end float of compressor crankshaft, can be corrected by installing Service Package, Part No. 2084466 as follows: Remove compressor from engine and remove rear plate. *NOTE – Remove base plate only if necessary for access to rear cover plate.* Remove old oil inlet connector from rear cover plate and install recessed connector supplied with package. Tighten to 130 inch lbs. Remove plug from end of crankshaft with tapping screw supplied with package. Set the 11-64" steel ball in chamfer at end of crankshaft, holding it in place with a small amount of heavy grease, then install spring in end of oil inlet connector. Use a new gasket and install rear cover plate on compressor with spring seated on steel ball. Tighten capscrews to 35 inch lbs.

DESCRIPTION: This air suspension system (on rear of car only) consists of an air piston and spring assembly mounted on an extension of the rear spring mounting plate directly forward of the rear axle assembly. The upper end of each air spring is connected directly to a transverse low pressure air tank which is mounted between frame side rails over the rear axle. A "bleed-feed" type height control valve connected to the low pressure air tank and linked to rear axle assembly at the center maintains a constant car height. Air is supplied to the system by a 2-cylinder reciprocating compressor mounted on the engine and driven by a belt from engine crankshaft. A high pressure air tank is mounted under the right front fender. *NOTE - Air compressor is lubricated by engine oil circulated from engine crankcase.*



OPERATION: With engine running at 1800-2000 RPM and car standing still, air pressure in high pressure tank is maintained at 220 lbs. ± 20 lbs. by the compressor. This high pressure air is supplied to the low pressure air tank and air spring assemblies through the height control valve to maintain the car at constant level under changing load conditions. The running pressure in air springs and low pressure air tank is approximately 20 lbs. (one passenger load and a full gas tank); 70 lbs. (six passenger load, except Station Wagons); 90 lbs. (nine passenger load, Station Wagons). A minimum valve incorporated in height control valve maintains a pressure of 8-15 lbs. in low pressure air tank and air springs to prevent damage to air springs when car is lowered to ground after being jacked up. The height control valve also has a high pressure relief valve which opens at 150 lbs. to protect system against extremely high pressures under excessive load conditions.

LUBRICATION: Air Compressor - Oil is circulated from engine oiling system and no special lubrication is required.

DRAINING HIGH PRESSURE AIR TANK: Drain tank at least once a month by depressing the non-removable

AIR SUSPENSION SYSTEM (SCHEMATIC)

AIR SUSPENSION SYSTEM

core in the drain valve. *CAUTION* - Should it become necessary to remove the valve, remove high pressure line at check valve first.

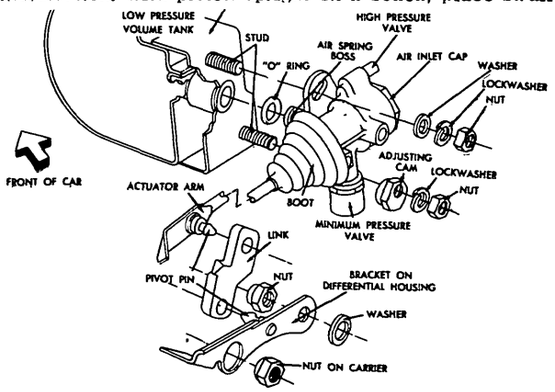
ADJUSTMENTS: Suspension Height - With front suspension height properly adjusted and within specified limits, tires at recommended pressure and gas tank full, place car on a level floor (with no passenger load), then proceed as follows: *NOTE - Rear suspension height is measured (both sides), once with load, and again without load. Both pairs of figures are compared as as well as averaged.* Run engine three to five minutes to stabilize pressure in system, then with engine running, add 150-200 lbs. of load to center of luggage compartment (height control valve should admit additional air to low pressure system causing car to return to original height). Measure height at both sides at a point between top of axle housing and highest part under the axle bumper straps, to rear of rubber bumpers, using Tool C-3670, and record the figures. Differences between sides should not exceed ½". *NOTE - If greater than ½", recheck front suspension height, particularly the difference between the two sides, and reset if necessary. If rear height continues to exceed ½", inspect rear springs as the inc rrect spring may be installed.* When difference is under ½", average the two figures for later use. Remove added weight from compartment and allow height control valve to bleed system for approximately 3 minutes. Measure rear heights and average the two figures. The difference between this average and the average previously obtained should not exceed ½". Adjust valve if necessary. Average the four measurements (do not average the two averages). The average should be 4¾"±1/8" (All models except Imperial); 4 3/8"±1/8" (Imperial). Adjust valve as necessary to obtain correct measurement.

Height Control Valve Adjustm nt: Loosen both attaching nuts, then rotate cam on lower attaching stud to adjust to correct car height. *CAUTION - Do not bottom cam tightly against valve body (low pressure volume tank port could be damaged).* Tighten attaching nuts to 100 inch pounds. Recheck rear suspension heights.

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH AIR SUSPENSION (C ntinued)

C mpr ssor B lt Adjustment: Without Air Conditioning - 9/16" (Used Belt), 5/16" (New Belt) deflection, all models, with a 5 lb. force midway between pulleys. **With Air C nditi ning** - ¼" (Used Belt), 1/8" (New Belt) deflection, except Chrysler Windsor & DeSoto Firesweep. 1/8" (Used Belt), 1/16" (New Belt) deflection, Chrysler Windsor & DeSoto Firesweep, with a 5 lb. force applied midway between pulleys. To adjust, loosen compressor bracket mounting bolts and move assembly as necessary.



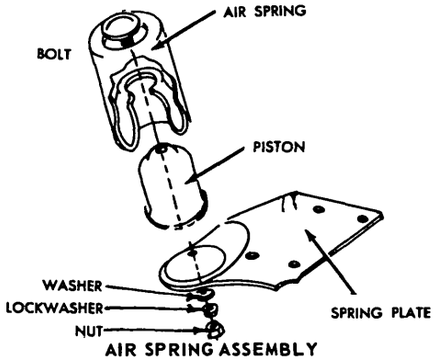
DISCHARGING THE SYSTEM: *CAUTION - Do not use from contact hoist wh n discharging the system.* Discharge high pressure system by depressing valve core in high pressure air tank drain and charging valve. DO NOT REMOVE VALVE FROM TANK. Discharge low pressure system by pulling the height control valve actuator arm off pivot pin on rubber linkage at the axle housing and moving the arm down.

REMOVAL & INSTALLATION

AIR SPRINGS & PISTONS: Removal – With car on hoist, discharge system. Remove nut holding air spring piston to spring plate, then raise piston off spring plate and remove air spring from lower pressure volume tank by pulling it outward and down. Remove piston mounting bolt and retainer assembly from piston, using a soft mallet. Push piston out of air spring by inserting a hammer handle into air spring. *CAUTION – DO NOT pull small end of air spring out to a fully extended position. Special tools are required to place it in the corr ct position.*

Insp cti n: Clean all parts, then inspect piston and mounting bolt assembly for nicks, burrs or cracks. Remove burrs with crocus cloth. Replace any piston showing indications of heavy cracks. Mounting bolt assembly must be snug fit in the piston and retainer section must seat solidly against piston. If necessary, peen piston around the bolt hole to obtain a snug fit. Inspect air spring for cuts, cracks, holes and excessive carcass wear. Small cracks in outer rubber cover are permissible provided there is no leak.

Installation: With piston upright on a bench, place small end of air spring over rounded end, then roll spring down to cover piston completely. Insert retainer bolt assembly and examine for snug fit in piston. Remove rear shock absorbers. *NOTE – Make hold-down straps or use Tool C–3694, and install them in place of shock absorbers. Strap will hold weight of body on leaf springs and assist in seating the air spring.* Position piston and air spring assembly on spring plate and install retainer bolt, washer, and nut. Tighten to 5 ft. lbs. temporarily. Coat mounting rim of air spring with diluted liquid soap solution. *NOTE – If both springs were removed from low pressure volume tank, it will be necessary to install both simultaneously to permit pressure build-up in tank.* Start engine, then hold air spring (or springs) tightly in position against tank seat (or seats) and operate control valve manually. Air pressure entering air springs will force spring up on its seat. Check seating of air spring on tank flange and seat of piston on spring plate. Align piston and tighten nut to 12 ft. lbs. Remove hold down straps and install shock absorbers. Connect actuator arm to rubber linkage, then check for air leaks.



HEIGHT CONTROL VALVE ASSEMBLY

HEIGHT CONTROL VALVE: Removal – Discharge system and remove high pressure line from valve and cap, then remove mounting nuts and valve assembly. *NOTE – Height control valves are serviced only as an assembly.*

Installation: Apply liquid soap to "O" ring on housing boss and install valve assembly on low pressure volume tank, inserting the boss in tank without damaging "O" ring. Install adjusting cam in housing at the lower mounting stud and install mounting nuts finger tight, then connect air line to valve end cap. Start engine and check valve for operation, then tighten mounting nuts to 7 ft. lbs. Connect actuator arm to rubber linkage and check for leaks. Check car height and adjust if necessary.

LOW PRESSURE VOLUME TANK: Removal – Discharge system, then remove air springs from tank. Disconnect air line at valve and cap. Disconnect actuator arm at rubber linkage, then loosen and lower right tail pipe only. Support axle and remove right rear wheel. Remove self-tapping screws (two on each side) holding tank to frame side rails. Remove tank from right side of car, then remove height control valve assembly and adjusting cam.

Installation: Install new "O" ring on height control valve air spring boss. Coat ring with diluted soap solution, then install valve assembly and adjusting cam. Tighten nuts to 7 ft. lbs. and install tank and tighten mounting screws to 13 ft. lbs. Connect air line to control valve and install air spring. Position and tighten right tail pipe, then install right rear wheel. Check system for leaks and adjust car rear height.

AIR SPRING ASSEMBLY

HIGH PRESSURE AIR TANK: Removal – Discharge system, then disconnect both air lines at tank and remove bolts holding tank cradle to car. Remove tank and bracket assembly, then remove bracket assembly and drain valve.

Instal lation: Install gasket and drain valve and tighten to 12 ft. lbs. Position tank and bracket assembly and install bolts. Tighten bolts to 7 ft. lbs. (¼"), 10 ft. lbs. (5/16"). Connect air lines to tank and check for leakage.

COMPRESSOR: Removal – Remove oil pressure line at rear of compressor. Remove air line from check valve, then remove oil return line at engine end. Loosen belt adjusting bolt, remove belt from compressor, then remove bracket bolt. Remove bolts holding compressor support to engine and remove compressor assembly from car.

Installation: With compressor attached to support, attach support to engine. Tighten bolts to 30 ft. lbs. Install compressor bracket and tighten bolts to 30 ft. lbs. Install belt, connect air pressure line, oil pressure and return lines. Start engine and check for leakage.

OVERHAUL

HEIGHT CONTROL VALVES: Serviced only as a complete assembly. Do not attempt overhaul.

COMPRESSOR: Only the following parts are available for service replacement: Cylinder head & gasket. Valve plate assembly & gasket. Pulley & Key. Bottom mounting plate & gasket. Front bearing, housing and oil seal assembly. Check valve assembly. Suction muffler felt. If piston, bearings, etc., are required, replace the complete compressor.

Cylinder Head Replacement: Discharge the system and remove air line from check valve, then remove cylinder head bolts. Remove cylinder head and valve plate assembly. *NOTE – If plate does not separate from head, tap plate lightly with a soft mallet. Do not pry apart.* Clean piston heads, top of cylinder block and head bolt holes, cylinder head and valve plate, using mineral spirits. Do not use a scraper. Inspect pistons and walls. If damaged, replace the compressor. If valve plate or cylinder head is damaged, replace. Remove check valve only if replacement is necessary. Use new gaskets when installing valve plate and cylinder head. Tighten bolts to 155 inch lbs. Connect air lines to check valve and then check for leaks and test compressor.

Valve Plate: *See "Cylinder Head Replacement" above.*

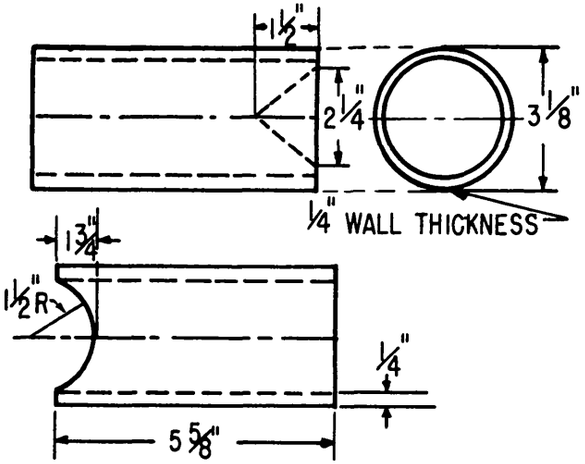
Pulley, Front Bearing Housing, Oil Seal Replacement: Remove compressor from engine. *NOTE – Original pulleys are a .002" press or interference fit on crankshaft. If pulley has been previously replaced, check to see if roll pin has been installed. If so, remove pin with a drift punch.* Remove pulley with tool PO–11, remove front bearing housing and seal assembly. Clean and inspect bearing and housing assembly. If damaged, replace the assembly. To reassemble, install front bearing housing using Tool C–3680 to protect oil seal. Tighten bolts to 17 inch lbs. Remove chrankshaft rear plate and install Tool C–3677 to support crankshaft while pressing pulley on crankshaft. Using an arbor press, press pulley into contact with flange on crankshaft. Remove tool and install rear cover plate. Tighten bolts to 17 inch lbs. *NOTE – A new pulley has a hole through one side of hub. Use this hole as a guide to drill a 5/32" hole in crankshaft and the opposite side of pulley hub.* Install a roll pin, then install compressor on engine.

FORD-AIRE SUSPENSION & MERCURY AIR CUSHION RIDE

Ford (1958)
Mercury (1958)

►CHANGES, CAUTIONS, CORRECTIONS

►*SERVICE CAUTIONS:* Before working under the car, jacking it up, or raising it on a hoist, the following precautions must be taken to prevent personal injury or damage to the car.



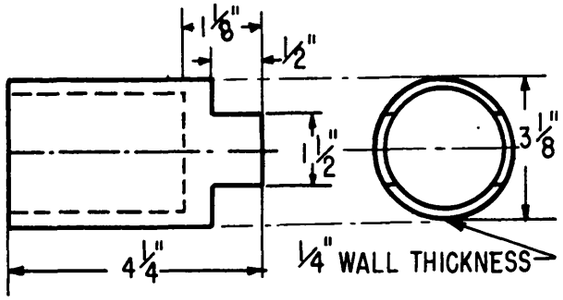
H isting Car: (Air Suspension Units Inflated): Hoisting equipment of the type that engages suspension, axle, or wheels *(see "Two-Post" hoist note below),* is preferred. When using a frame contact type hoist, make certain that proper adapters are used to prevent contact with rear shock absorbers or suspension links.

►*TWO-POST HOIST NOTE:* At the rear, make certain rear axle housing centers over hoist post center. Check where rear saddle jaws will contact rear axle. If necessary use special adapters to prevent damage to rear shocks, track bar, gas tank, etc. In instances where front air springs are extremely low or deflated the front hoist rail will contact oil pan and may result in damage to oil pan, oil pump and vacuum pump. If available, install shipping pedestals *(see "Hoisting Car, Air Suspension Units Deflated" below).* If pedestals not available, install small wooden blocks between lower suspension arm and hoist saddles to provide clearance for oil pan.

Hoisting Car (Air Suspension Units Deflated): Jack up car at front and rear and install shipping pedestals *NOTE* - These may be procured from car dealer . Front pedestals are installed between lower arm jounce bumper and its contact surface on side of upper spring "beehive" on frame. Rear pedestals are installed between rear axle housing and rear axle bumper. Lower jack and allow weight of car to rest on pedestals.

Working Under The Car - Before using a creeper or crawling under an air suspension car, place jack stands under the frame as a precaution in case air should be exhausted from the system.

Towing: When towing air suspension car on which air suspension is inoperative, special support blocks (see illustration, or use Tool T58P-5783-A which includes a special set of blocks) are required to prevent bumpers from scraping the ground, as follows: When towing car by front bumper, install rear blocks on frame just above rear axle housing. Upper half of block encases rubber bumper on frame. Lower half of block rests on and partially encircles rear axle housing. When towing car by rear bumper, install front blocks over rubber bumpers so bottom of block rests on front suspension arm. *(CAUTION - B for installing support blocks, raise front or rear of car as required, and place support jacks under car).* If car is to be towed from the rear for long distances, it is recommended rear axle and No. 4 crossmember be chained together to prevent damage to rear shock absorbers.



MERCURY REAR TOWING BLOCKS

►*PRESSURE REGULATOR FITTING LEAKAGE CORRECTION:* On early cars with air suspension, leakage at pressure regulator fittings can be eliminated by installing two seal washers, Part No. 370868-S in each port of regulator assembly. Two seals are being installed in fittings on later production cars.

►*FORD AIR COMPRESSOR MOUNTING BRACKET PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* A new mounting bracket, Part No. B8A-55205-B is now being used in production and is available for service replacement on earlier cars. If bracket distortion is encountered on early cars, replace bracket with the later type.

DESCRIPTION: Air springs, consisting of a hollow rubber cylinder within a metal container, and a piston assembly replace conventional front coil springs and rear leaf springs. Two rear suspension arms connected between rear axle and frame side members maintain fore and aft position of rear axle and absorb driving and braking forces. A track bar mounted across rear end of car connects rear axle housing and frame to prevent rear axle side motion. Car leveling and riding height are maintained by two leveling valves at front, and a single valve at rear. Valves are mounted on car frame and connected by linkage to rear axle housing (rear), and the two upper control arms (front). Fast leveling of the car is provided, when any door is opened, by switches

MERCURY FRONT TOWING BL CKS

located at each door which control an electric solenoid valve in the high pressure air line. Check valve located between the two rear air springs and at each front air spring prevent air pressure in air springs from completely discharging should leak occur elsewhere in the system. On Mercury, a low pressure warning light on left side of instrument panel operates when pressure in air tank drops below 125 lbs. Basic components of system operate as follows:

Air Compressor: Single cylinder, reciprocating piston type mounted on right front side of engine and driven off engine water pump pulley by a single "V" belt. The compressor is lubricated by engine oiling system through a line from filter outlet connection directly to compressor crankcase.

Air Reservoir: This tank, located under right front fender, has a check valve at inlet port to prevent air pressure being exhausted through compressor when engine not running, a filter at outlet port, and a Schrader type relief valve which also acts as a condensation drain valve.

Leveling Valves: Two leveling valve assemblies are located at the front, one at each spring, and a single leveling valve at rear which controls both rear springs. These valves are connected by mechanical linkage to front and rear suspension members and are used to maintain a constant car riding height by admitting air to, or exhausting air from, air springs to compensate for varying load conditions. Air is admitted to these valves either through the copper (low pressure) line at approximately 160 lbs. pressure, or through the nylon (high pressure) line at approximately 300 lbs. pressure, and is exhausted to atmosphere directly from an opening in bottom of the valve.

CONTINUED ON NEXT PAGE

FORD & MERCURY AIR SUSPENSION (Continued)

Check Valves: Located at each of the leveling valve assemblies and prevent air pressure in the air spring from dropping below approximately 65 lbs., due to air leakage at some other point in the system.

Restrictor Valve (Front): Located in the line between the two rear air springs and is connected to both the slow-leveling system and the fast-leveling system, controlling the flow of air between the two rear springs.

Pressure Regulator Valve: Supplies reduced air pressure from air reservoir to the leveling valves for slow-leveling operations.

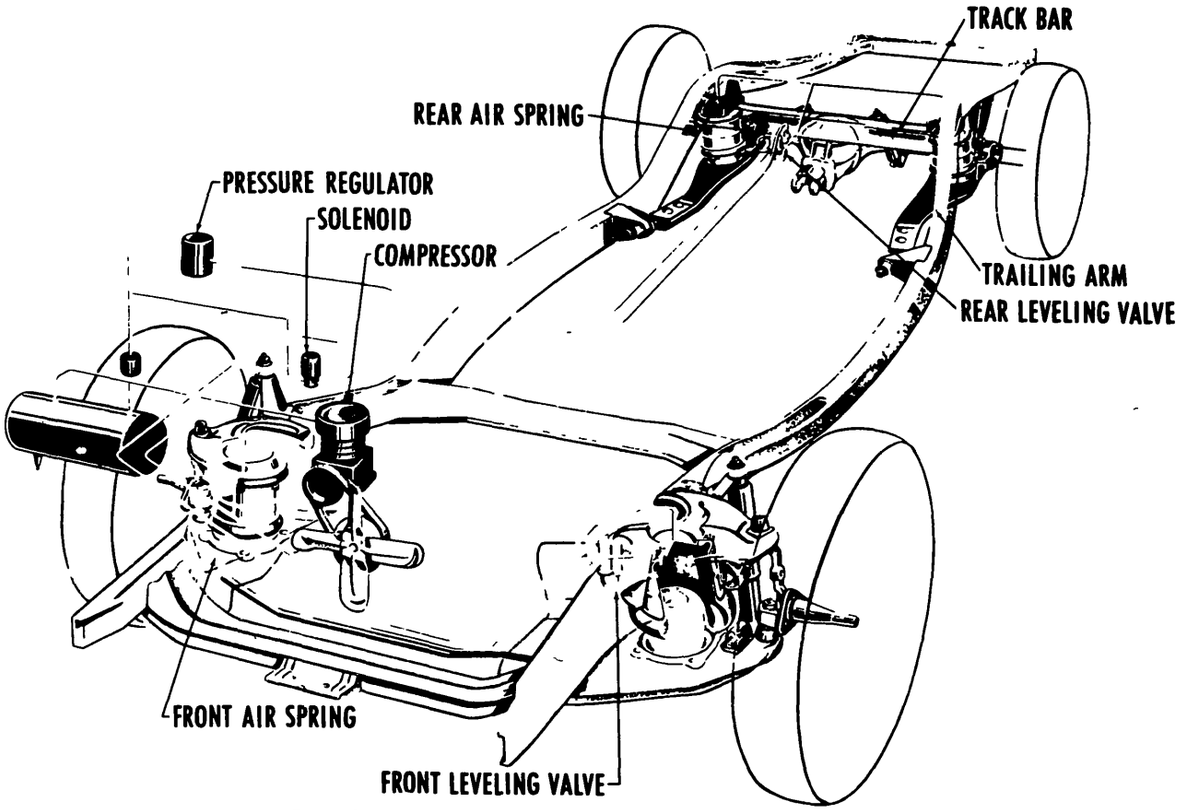
Solenoid Valve: This valve is electrically operated when a car door is opened and supplies high pressure air to the leveling valves for fast-leveling operation. The solenoid valve also operates as a pressure relief valve for the system and will open at 400 lbs. pressure should the system pressure become abnormally high.

Low Pressure Air Lines (Copper): These lines supply air from the pressure regulator to the leveling valves for slow-leveling operation.

High Pressure Air Lines (Nylon): These lines supply air from the solenoid valve to leveling valves for fast-leveling operation.

Air Springs: Each air spring consists of a pedestal (piston) which is connected to the lower control arm (front), or to the suspension arm (rear), a hollow rubber air spring, an air spring container, and an upper end plate and seal. The rear air spring assembly also contains a mounting flange which is used to bolt the air spring assembly to the frame side member.

DRAINING AIR RESERVOIR: Every 1000 miles, drain accumulated moisture, dirt, and oil from air reservoir under right front fender. Push in on valve stem (same as tire valve) located on under side of air reservoir.



AIR COMPRESSOR INTAKE FILTER: Ford - Clean filter every 8000 miles under normal operating conditions (every 2000 miles under dusty conditions), in solvent. Saturate "curled hair" element in engine oil and squeeze dry before installation.

Mercury: Clean filter every 4000 miles. Replace filter every 10,000 miles.

ADJUSTMENT

RIDING HEIGHT ADJUSTMENT: Adjust front and rear riding height by shortening or lengthening linkage connecting each of the leveling valves to suspension members. Riding height should be as indicated below. *NOTE:* Riding height at rear should be an average of the right and left hand sides.

Front: (Front) - 3 1/4" ± 1/16" measured between top edge of lower control arm bumper bracket and lower outside edge of spring pocket on the frame.
Rear - 4" ± 1/16" measured between top of rear axle housing and bottom of axle bumper bracket.

FORD & MERCURY AIR SUSPENSION SYSTEM (SCHEMATIC)

Mercury: (Front) - 4 11/32" (all models) measured between top of air spring lower plate and lower outside edge of spring pocket on frame.
Rear - 5.57" (122" wheelbase), 5.63" (125" wheelbase) measured between top of rear axle housing and bottom of axle bumper bracket.

AIR COMPRESSOR BELT ADJUSTMENT: Loosen air compressor mounting bracket and adjust belt so there is 1 2" deflection with normal thumb pressure midway between the two pulleys.

FRONT END ADJUSTMENT: Same as for cars with conventional coil springs. *See "Front Suspension" on Car Model pages.*

TROUBLE SHOOTING

Car Settles Down: Leakage in system. Check system with a Freon leak detector.

Car Remains High: Check adjustment of leveling valves. If valve is defective and will not exhaust air, remove, disassemble, and clean valve. See "Leveling Valves". *NOTE* - A sticking "Tee" check valve will also cause the above condition. Remove valve and blow out the passages. If valve continues to stick, replace valve.

Car Remains Low: Check leveling valve adjustment. Check reservoir check valve. If valve is sticking, disconnect pressure line at tank and push valve off its seat to clean it. If valve continues to stick, replace it. A sticking "Tee" check valve will also cause the above condition. Remove valve and blow out passages. If valve continues to stick, replace valve. Check compressor at 1200 RPM. If output is less than 275 lbs., replace or repair compressor. Check pressure regulator valve. With engine running, pressure should be approximately 160 lbs., with gauge connected to low pressure line at either front leveling valve.

Car Remains Low at Rear (or on one side only at rear): Remove and clean restrictor valve by blowing out all passages. Replace valve if it continues to give trouble. Check operation of leveling valves.

Car Does Not Respond Immediately on Fast Leveling (Operates Satisfactorily on Slow Leveling): Check operation of solenoid valve. Remove solenoid pressure line from either front leveling valve and install a 400 lb. gauge. With engine running to maintain full reservoir pressure, and one door open, pressure on gauge should be approximately 275-375 lbs. If no pressure is indicated on gauge, disconnect solenoid valve bullet connector and connect to positive terminal of battery. Ground valve mounting bracket to negative terminal of battery and check pressure gauge. If gauge reading is within specifications, door contact switches should be checked. If no pressure exists, replace solenoid valve.

CONTINUED ON NEXT PAGE

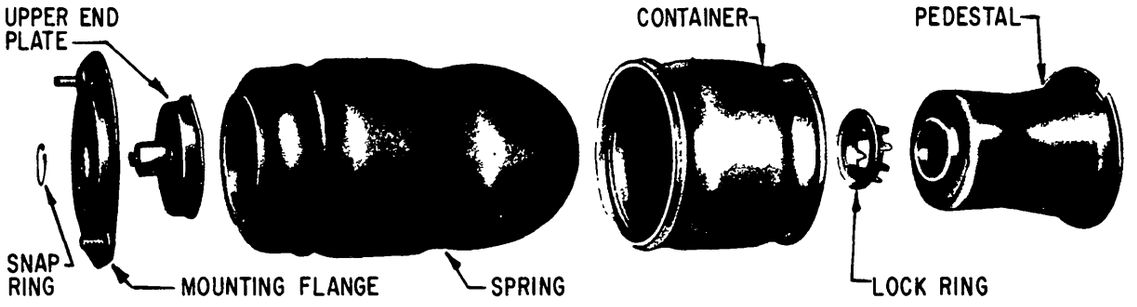
FORD & MERCURY AIR SUSPENSION (C ntinu d)

Car Rolls Excessively on Turns: Check restrictor valve piston to determine if it is sticking in fast leveling position. Replace valve if trouble continues after cleaning.

REMOVAL & INSTALLATION

LOWER CONTROL ARM: Removal & Installation - Raise and support car, then exhaust air from system. Disconnect air spring pedestal from lower control arm and remove arm from car in same manner as for coil spring cars *(see "Ford & Mercury Front Suspension")*.

REAR SUSPENSION CONTROL ARMS: Removal & Installation - *See "Ford & Mercury Rear Suspension (Air Suspension Cars)".*



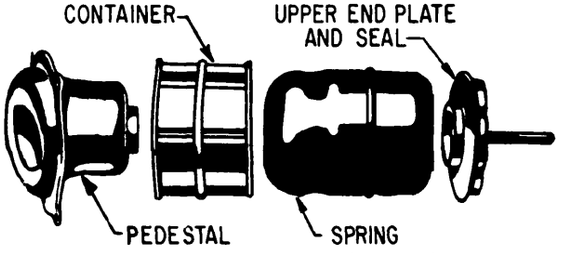
AIR COMPRESSOR: Removal - Exhaust all air from system by opening drain valve on air reservoir. On Ford models, disconnect air outlet tube. On Mercury models, disconnect oil supply line, oil outlet line, and air outlet line. On all models, loosen compressor adjusting strap bolt and compressor mounting bracket bolts, then remove belt. *NOTE* - On air conditioned cars, remove air conditioner compressor belt before removing air compressor. On Ford models, rotate compressor to gain access to compressor crankshaft rear end plate. Remove rear end plate retaining screws. On all models, remove compressor from engine.

Installation: Reverse removal procedure and note the following: On Ford, install a new "O" ring seal in crankshaft rear end plate. On all models, tighten mounting bolts to 12-15 ft. lbs.

FRONT AIR SPRING (FORD): Removal - Raise and support front of car with jack stands placed under frame side rails. Disconnect air line at top of spring and allow air pressure to slowly escape *(CAUTION* - Do not remove fitting with spring under pressure). Remove spring nut and rubber insulator from upper end of spring seal plate, then remove four nuts, bolts and lockwashers holding pedestal to lower control arm. Push pedestal up into spring until bottom of pedestal is above lower control arm, then remove air spring.

Installation: Position spring assembly between upper and lower control arms, making sure the locating slot on upper end plate seal is lined up with corresponding tab on upper control arm. Secure pedestal to lower control arm. Slide rubber insulator and spring nut over air line fitting on upper seal plate fitting, then connect air line fitting to air spring.

FRONT AIR SPRING (MERCURY): Removal - Support car on jack stands placed under each frame side rail adjacent to No. 1 crossmember. Remove wheel, then loosen stabilizer retaining bolt to allow front suspension to drop into full rebound position. Disconnect air line at "Tee" check valve, allowing air to be exhausted from air spring assembly. Remove upper suspension arm rubber bumper retaining nut; and raise the lower suspension arm. Remove rubber bumper, then drop the lower arm. Remove upper and lower air spring retaining nuts. Compress spring and pedestal assembly; rotate ½ turn, and remove by sliding lower pedestal toward rear of car.



FORD & MERCURY REAR AIR SPRING ASSEMBLY

Installation: Compress spring and pedestal assembly as far as possible, then insert tube up through hole in top of upper spring seat. Slide lower pedestal assembly into approximate position on lower suspension arm. Holding air spring in place against upper seat, place rubber insulator and Tinnerman nut on air tube of locator assembly, and tighten until they seat firmly against upper seat. Raise lower suspension arm and attach rubber bumper to upper suspension arm. Secure pedestal assembly to lower suspension arm and tighten to 22-28 ft. lbs. Tighten stabilizer bar retainers to 22-28 ft. lbs. Attach air spring line to "Tee" check valve. Place shipping pedestal (towing blocks) between lower suspension arm and frame to prevent complete collapse of air spring when car weight is placed on wheels. Install wheel. Remove support stands, then start and run engine. Remove blocks when spring is inflated. Check for leakage, then check and adjust riding height.

REAR AIR SPRING (FORD): Removal - Loosen, but do not disconnect, air line at top of spring to allow pressure to bleed out. After pressure has escaped, disconnect air line. Remove brass adapter and copper washer from spring and discard washer. Remove lower mounting nut, then remove both nuts retaining upper spring mounting pad to frame. Remove air spring assembly.

Installation: Position rear spring assembly between the frame and rear suspension arm, making sure that locating slot on pedestal is lined up with corresponding tab on rear suspension arm. Install nuts securing upper mounting plate to frame, then install lower mounting nut. Install air line adapter and a new copper gasket. Connect air supply line to spring.

REAR AIR SPRING (MERCURY): Removal - Raise car and support with jack stands under each frame side rail adjacent to No. 5 crossmember. Blow dirt from around air spring, then disconnect air line at spring side of check valve to exhaust air from spring. *(NOTE* - With rear suspension in rebound position, no air will be lost from rest of system). Disconnect air line from air spring assembly. Remove nuts and lockwashers attaching air spring assembly to upper rear spring mounting bracket, then remove nut and lockwasher attaching air spring to trailing arm assembly. Support rear axle with a hoist and remove rear shock absorbers, then remove air spring from car. *(CAUTION* - Do not allow suspension to exceed full rebound position).

FORD & MERCURY FRONT AIR SPRIN ASSEMBLY

Installation: Position air spring assembly between upper frame support and trailing arm assembly, then loosely attach air spring to upper frame support. Attach air spring lower mounting stud to trailing arm and tighten to 22-28 ft. lbs. Tighten air spring to upper frame support being careful not to twist air spring assembly. Connect air line to spring assembly and to check valve. Place towing block (see above) between trailing arm and frame to prevent complete collapse of air spring when car weight is placed on the wheels. Remove support stands and lower car. Operate engine and inflate air spring, then remove towing block. Check for leakage, then adjust riding height.

LEVELING VALVE (FORD & MERCURY): R m val - Raise car and support with jack stands at front and rear of frame side rails. Open drain valve on air reservoir and exhaust all air from system. Disconnect actuating lever from leveling link, then depressurize air spring. Disconnect high and low pressure lines at leveling valve. Remove nuts from mounting brackets and remove leveling valve.

Installation: Reverse removal procedure, then adjust riding height of car.

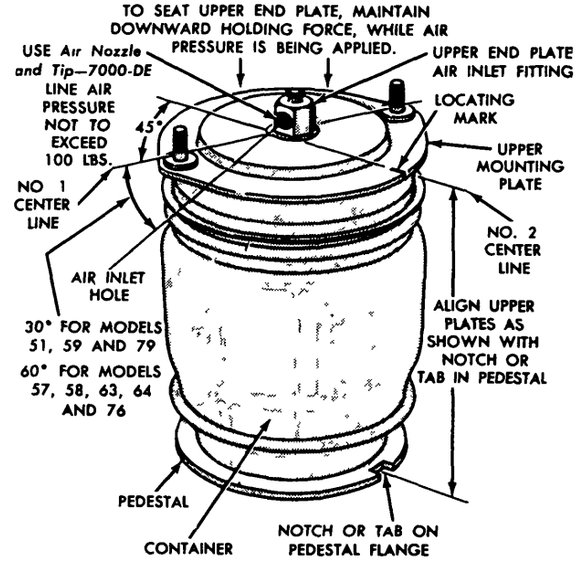
SHOCK ABSORBER REMOVAL (REAR): When rear shock absorbers have been removed, car should be raised only by picking it up underneath rear axle assembly. Raising the car at any point which will allow rear suspension to hang freely would result in damage to air spring assemblies.

OVERHAUL

AIR COMPRESSOR: *See "Air Susp nsion Air C mpr s- sor".*

LEVELING VALVE: *Se "L v ling & Mannual Control Valv s".*

CONTINUED ON NEXT PAGE



FORD & MERCURY AIR SUSPENSION (C ntinued)

AIR SPRING (FRONT): Disassembly - Remove upper end plate and seal from spring assembly by pulling plate off spring. Remove container from spring, then remove pedestal from spring. If pedestal does not come off easily, it can be forced off with a screwdriver between pedestal and spring. Clean all metal parts in solvent and dry with air. Check end plate seal and pedestal for burrs or sharp edges and remove if necessary. Wash air spring with soap and water and dry with a clean cloth. Inspect air spring for wear at ends and around the container area. If excessive wear is found, replace air spring.

R ass mbly: Apply a generous amount of RuGlyde on lower end of spring and on pedestal retaining lip. Position spring on pedestal and push spring down until lower opening is flush with upper opening. Place assembly in a vise to hold edge in place, using the vise to seat one side of spring on pedestal lip *(CAUTION* - Be careful not to damage bead on air spring). Insert a blunt screwdriver between spring opening and pedestal, and push spring into place. Remove assembly from vise and pull spring back to normal shape, then install container. Again push spring assembly down over pedestal. Apply a generous amount of RuGlyde at critical area and position upper end plate over spring opening. *(NOTE* - Notch in pedestal and notch in upper end plate must be in alignment). With one person holding air spring assembly, carefully and slowly inflate air spring until upper end plate seats in spring. If leaking air indicates that upper end plate is not sealing properly to permit assembly, relocate the plate for a more satisfactory seal.

AIR SPRING (REAR): Disass mbly - Remove snap ring from upper end of spring assembly and remove upper mounting plate. Remove end plate by pushing the plate inside spring, then turning plate on edge, and pulling it back out of spring. Position spring assembly in a vise by clamping vise at pedestal base. Insert a blunt screwdriver between pedestal and spring to force spring from Pedestal. *(CAUTION* - Do not damage air spring). Remove pedestal, then remove container from spring. Wash all metal parts in solvent and blow dry with air. Inspect end plate and pedestal for burrs or sharp edges and remove as necessary. Clean air spring with soap and water, then wipe dry. Inspect for wear at end plate and container area. Replace if necessary.

Reassembly: Slide container over air spring, then apply a generous amount of RuGlyde to lower end of spring assembly and position spring on pedestal. Push pedestal all the way through air spring until lock ring surface is exposed. Place spring assembly in a press, using Tool T56T-4221, then press spring down on pedestal seat. Install lock ring and bend tabs toward outside of spring, using water pump pliers. Push pedestal back through spring to its normal position and install upper end plate in spring. While holding end plate by the fitting to prevent dropping it in spring, push spring down over pedestal. Make a prominent locating mark on edge of mounting plate at the No. 2 centerline (see illustration for locating points). Position mounting plate over end plate fitting so centerline No. 1 is at either 30° or 60° to the air inlet, according to the model as indicated in illustration. *(NOTE - Mounting plate is machined to position over hex at 30° intervals).* Grasp edge of mounting plate

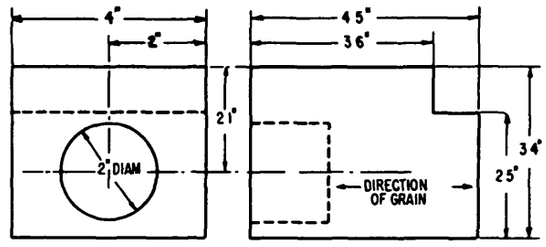
FORD & MERCURY REAR AIR SPRING ASSEMBLY

and turn complete assembly until locating mark (centerline No. 2) is aligned with notch or tab on pedestal (see illustration). After properly positioning upper end plate and upper mounting plate, hold upper end plate by the fitting and pull up to position the fitting firmly in mounting plate hole. Apply air pressure to fitting until end plate has seated in spring, then install snap ring.

OLDSMOBILE NEW-MATIC RIDE

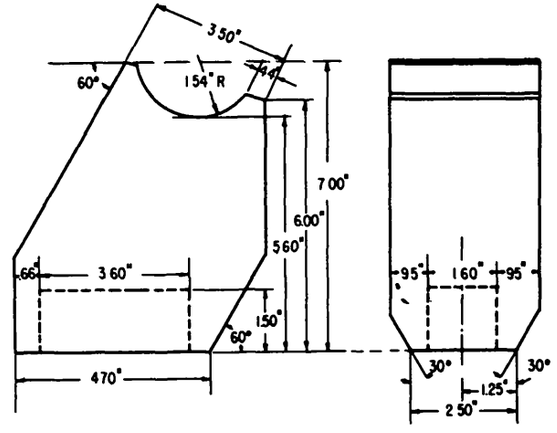
Oldsm bil (1958-59)

►CHANGES, CAUTIONS, CORRECTIONS



►*SERVICE CAUTIONS:* Before disconnecting air lines, working under car, or raising car on hoist, the following precautions must be taken to prevent personal injury or damage to car.

Raising Car (On a Jack) - Raise car in same manner as with conventional suspension (**do not** pull out on air suspension manual lift knob). When jack is lowered at right or left front of car, front end will follow jack down to slightly below normal, but will automatically raise to correct level. When jack is lowered at right or left rear, only the side supported by the jack will follow jack to slightly below normal position.



Raising Car (On Twin-P st Hoist) - Use caution to prevent left hand yoke of rear hoist contacting hydraulic brake hose or junction block on rear axle housing.

Raising Car (On Fram -Contact Hoist) - Wheels will drop and exhaust air from air springs. When hoist is lowered, car frame may continue to rest on hoist until air springs are inflated (it may be necessary to start engine for sufficient pressure). *CAUTION* - Do not pull out on air suspension manual lift knob while car is in a raised position.

►*TOWING THE CAR: (CAUTION - D not tow car with rear wheels on ground unless propeller shaft is disconnected).* When towing with front or rear wheels off ground, with air in suspension system, check air pressure in tank which should be above 100 lbs. Hook up tow chains or cables *(CAUTION - Do not attach chains to suspension arms at front of car).* Raise car and remove wheels from raised end, then lower car to horizontal position. DO NOT tow car at speeds in excess of 30 MPH. If air is exhausted from system, or body of car carries too low while towing, raise body of car (at end which is on ground) and install towing blocks (see illustration) as follows: At the rear, position radius of blocks

OLDSMOBILE FRONT TOWING BLOCKS

OLDSMOBILE REAR TOWING BLOCKS

on axle housing and align hollow in blocks with rubber bumper on frame. At the front, position hollow of block over rubber bumper on lower control arm. Lower body on blocks making sure that rubber bumpers enter hollows

CONTINUED ON NEXT PAGE

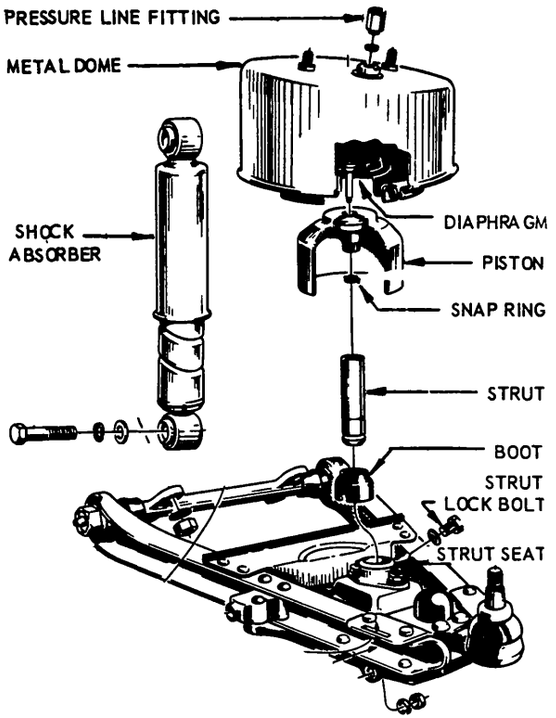
OLDSMOBILE NEW-MATIC RIDE (C ntinued)

in blocks at rear of car or that frame rests on right angle offset of block at front of car. If rear end of car is raised, steering wheel must be centered and tied in position. *CAUTION - Distance from bottom of tire to ground at raised end should not be more than 6", and towing speed should not exceed 30 MPH.*

Disconnecting Air Lines - When removing tubing connections from units on the car, loosen connection and allow pressure to leak down slowly before removing the fitting.

Working Under Car - Always place jack stands under car frame as a precaution in case air should be exhausted from the system.

►*1958 HIGH PRESSURE AIR VALVE (IN SEPARATOR) HANGING UP CORRECTION:* A restriction in air flow due to high pressure check valve hanging up can be corrected as follows: Exhaust all air pressure by opening drain valve on separator, then remove high pressure check valve plug. Remove spring and high pressure check valve. *NOTE - Check valve may not come out with its spring, in which case, force valve out by using air pressure through bottom of drain valve opening while holding a cloth over check valve opening.* Use a sharp knife or razor blade and cut off 1/8" from square end of check valve, then sand a 1/16" radius using fine sandpaper, around diameter of cut area on valve. Reinstall valve, spring, and plug, making sure that parts are clean.



DESCRIPTION: *NOTE - 1958 and 1959 systems are different as indicated below:*

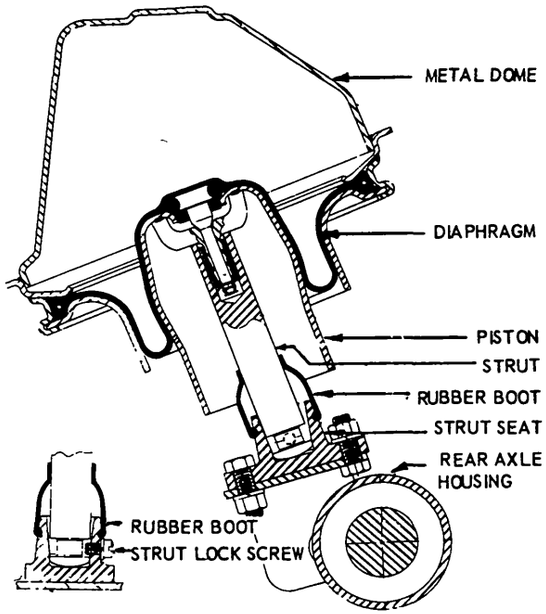
1958 Models; Air springs, consisting of an air chamber and rubber diaphragm assembly attached to frame and a piston assembly attached to lower control arm (front), axle housing (rear), replace conventional coil springs at front and leaf springs at rear. Normal riding height is maintained automatically by air pressure controlled by two height control valves (rear), one control valve (front). A manually operated elevator valve assembly located on left side rail is operated by a control cable and knob on instrument panel. This valve, when actuated by the control knob, provides air to all four springs when conditions require car body to be raised above normal height. When raised to full rebound position, the car body will be raised approximately 4 inches. Basic components of the air suspension system operate as outlined below.

1959 Models: Same design as used for 1958 models (above) except for changes to allow for an "open" type air circuit (air exhausted from air springs is not returned to compressor through a low pressure circuit). Basic components of the air suspension system operate as outlined below.

OPERATION: Except as noted, 1958 and 1959 systems and components are similar.

Air Compressor: Two cylinder reciprocating type with a rated capacity of .5 cu. ft. per minute with 250 lbs. pressure at 1250 compressor RPM. Compressor is lubricated with a two stage vane type pump which draws oil from a reservoir in the power steering pump. A relief valve limits lubrication pressure to approximately 24 lbs.

OLDSMOBILE FRONT AIR SPRING



Air Filter & Check Valve Assembly (1959 Models): This combination unit is located in the system between high pressure side of compressor and high pressure tank at a point adjacent to manual valve. The filter unit removes water and solid particles which are collected in bottom of reservoir shell. A drain cock, located in bottom of shell, should be opened every 2,000 miles to drain filter shell.

High Pressure Reserve Tank (1958 Models): Mounted on frame behind right rear wheel. This tank is used to maintain a reserve supply of high pressure air and serves to trap moisture. A Schrader type valve is provided in rear of tank for discharging accumulation of water and oil.

High Pressure Tank (1959 Models): Located on left frame side rail at rear of car. The high pressure tank supplies pressure to air spring to compensate for uneven weight distribution when compressor is not operating. A drain cock is provided on end of tank to remove moisture. Moisture from bottom of tank leaves the drain cock through a permanently positioned metal tube. Drain moisture from tank every 2,000 miles.

Low Pressure Air Tank (1958 Models): Mounted on frame behind left rear wheel. This tank is used to receive air released from air springs by the height control valves to be returned to compressor. Use of this tank provides a silent discharge of air from air springs as well as to reduce amount of outside air taken into system.

Separat r Assembly (1958 Mod ls): Mounted on frame ahead of left front upper control arm. This unit has five functions as follows: Filters incoming air. Separates

OLDSMOBILE REAR AIR SPRING

oil, moisture, and foreign matter. Prevents air in high pressure tank from exhausting through compressor when engine not running. Limits pressure in low pressure system air tank to approximately 70 lbs. maximum. Prevents air in low pressure tank from exhausting through compressor when engine not running.

Manual Override Valve: This valve consists of a pressure regulator and a manually operated elevator valve (lift valve) and is located at left front of car. The pressure regulator regulates air pressure from the high pressure tank down to 155–165 lbs. The manually operated elevator valve which is controlled by a cable connected to a handle located beneath the instrument panel, allows the car to be raised to the full rebound position.

Rear Height Control Valves: There are two rear height control valves mounted on the frame (one at each side) and actuated by linkage connected to the rear axle housing. They act not only to control height of rear of car but also to maintain proper height of the right and left side of car to maintain it in a level position.

Front Height Control Valve: The single front height control valve is mounted on the number one crossmember and is actuated by linkage connected to the front stabilizer bar. Its function is to increase or decrease air pressure in the front springs to compensate for differences in car loading to maintain proper car height. Rotation of the front stabilizer bar operates the linkage to actuate the height control valve

Air Springs: Each unit consists of a metal air dome and a rubber diaphragm assembly attached to the frame, and a piston and strut assembly that is attached to lower control arms in the front and the axle housing in the rear. Pressure in the air springs is controlled automatically

CONTINUED ON NEXT PAGE

OLDSMOBILE NEW-MATIC RIDE (C ntinued)

by the height control valves to compensate for differences in car loading.

LUBRICATION: Check fluid level in power steering pump every 2,000 miles and maintain level at "Full" mark on filler neck of power steering pump reservoir. *CAUTION – Use only Synthetic Fluid, GM Part No. 577080 to replenish reservoir.*

Piston Strut Seat: Lubricate front and rear seats every 26,000 miles using Special Lubricant, Part No. 571035, as follows:

Front - Raise front of car so wheels are hanging free, then disconnect air spring line from front height control valve (shortest adaptor on height control valve) Remove strut retaining bolt from strut seat and disengage rubber boot. Remove strut seat attaching bolt, and seat. Wash out seat and end of strut with clean solvent and blow dry with air. Reinstall strut seat and lubricate with ¼ ounce of Special Lubricant, Part No. 571035. Reinstall strut in seat using a new boot. Connect air line, using a new seal and slowly lower car. Operate engine if necessary to bring car to normal riding height.

R ar – Raise and support car at frame to relieve weight from wheels. Loosen pressure line at the air spring and allow air pressure to exhaust. Pull dust seal away strut seat and loosen seat setscrew almost to limit of its threads. Remove strut seat attaching bolts and remove strut seat by raising strut into piston for clearance. Clean strut and strut seat and lubricate with ¼ ounce of Special Lubricant, Part No. 571035. Reinstall strut in seat using a new boot. Connect air line using a new seal and slowly lower car. Operate engine if necessary to bring car to normal riding height.

AIR INTAKE FILTER (1958): Clean air filter on the separator assembly every 4,000 miles (more often if car is operated under dusty conditions). Unscrew filter from separator and wash in a petroleum base solvent. *CAUTION - Do not use compressed air to dry filter as this will separate filtering material.*

AIR INTAKE FILTER (1959): Drain filter every 2,000 miles. To drain unit, open drain cock on bottom of reservoir shell until air pressure has expelled water and oil. *NOTE - If there is no pressure in filter, momentarily start engine to build up pressure, then stop engine and drain unit.*

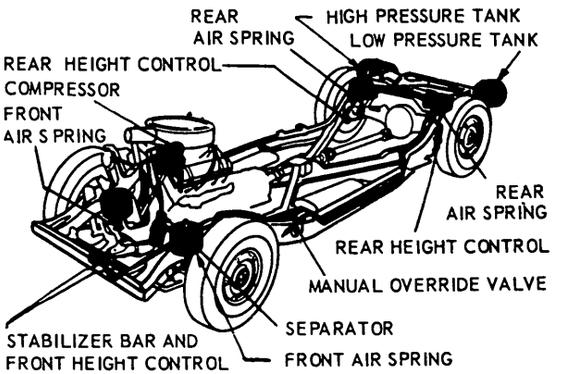
DRAINING SEPARATOR ASSEMBLY (1958): Drain water and oil accumulation from separator assembly every 2,000 miles as follows: Open drain valve on bottom of separator assembly and allow air pressure to force out water and oil. Close drain valve when discharge of water and oil stops.

DRAINING HIGH PRESSURE AIR TANK (1958): Drain water and oil accumulation from tank every 4,000 miles as follows: Remove cap from Schrader valve at back end of tank and depress valve stem until discharge of water and oil stops.

DRAINING HIGH PRESSURE AIR TANK (1959): Drain tank every 2,000 miles as follows: Open drain cock located at rear end of tank until air pressure has expelled all water and oil.

ALCOHOL VAPORIZER (Dealer Installed Unit): Check fluid level every 2,000 miles during winter months and fluid added to keep jar ¾ full. Use a non-permanent type anti-freeze (colorless methyl alcohol) to replenish fluid. Every 2,000 miles, check, and if necessary, clean vaporizer air inlet filter. Clean filter in solvent and blow dry with air (low pressure).

Vaporizer Spring Maintainenc : After the winter season, drain vaporizer and remove vaporizer-to-compressor hose and the rubber cap from carburetor air cleaner hose connection. Place hose and cap in trunk compartment. Reinstall short air cleaner-to-compressor hose.



Vaporizer Fall Maintainence: Remove short air cleaner-to-compressor hose and install the rubber cap on air cleaner hose connection, then install vaporizer-to-compressor hose. Fill jar ¾ full with colorless methyl alcohol.

ADJUSTMENT

ADJUSTMENTS: Compressor Belt – Use Gauge 33–70 to check belt tension. *NOTE – Pointers on sleeve of tool must index with groove on tool plunger.* To adjust, loosen idler pulley bracket bolts and insert a flex handle in the ½" square hole provided in idler pulley bracket and pivot bracket until pointers on Gauge 33–70 index with line on tool plunger. Tighten idler pulley bracket bolts to 20–28 ft. lbs. Check the other belt. If it is outside gauge limits, replace both belts as a matched set.

Elevator Valve (1958 Models): *NOTE - Elevator valve is not serviced other than by replacement or by adjustment of control cable and stopscrew. DO NOT attempt to change adjustment of pressure regulator adjusting screws. This is set in production to 145-155 lbs. and must not be changed.* To determine if elevator valve lever stopscrew requires adjustment, disconnect low pressure line identified by stamping on valve("To L.P. Tank"), from valve. **Air will exhaust from low pressure line.** If air exhausts from elevator valve, it will be necessary to adjust actuating lever stopscrew and cable (see below). If valve stopscrew adjustment is correct, adjust cable (see below).

Cable Adjustment - Remove actuating lever and spring from elevator valve and check freeness of cable in housing. If cable binds, remove kinks in housing and make sure cable is free. Reinstall actuating lever and spring. Loosen cable housing clamp at body floor pan or frame and remove excessive slack from cable by sliding housing through clamp, then tighten clamp. To recheck, pull out elevator handle on instrument panel slightly. There should be 1/8" free movement in cable and no air should escape while cable is moved 1/8".

1958 OLDSMOBILE AIR SUSPENSION SYSTEM

Pull out elevator valve handle about half way. Air should escape from elevator valve at disconnected fitting. Release elevator lever handle slowly and allow spring tension to draw cable through housing to close valve. Air should not escape from valve. If air escapes, the cable is binding or actuating lever is incorrectly adjusted. Recheck if necessary. To check if valve seats properly in elevated position, pull elevator valve cable all the way out. Air should blast out of elevator valve momentarily, but should stop after check valve has seated for elevated position. If air does not stop, repeat the above adjustment. Also check for defective check valve in elevator valve, in which case elevator valve assembly must be replaced. Replace low pressure line to elevator valve and install valve baffle.

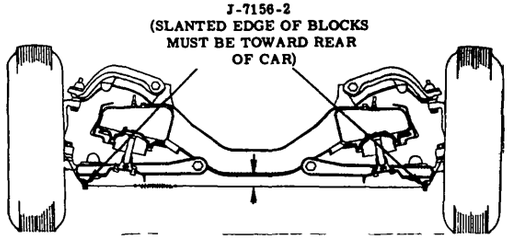
Lever Stopscrew Adjustment - Raise car and remove elevator valve baffle plate, then remove actuating lever and spring and check freeness of cable (see above). Loosen locknut on stopscrew and turn screw in until air just starts to escape from elevator valve. Back off screw until leak stops, **then back off an additional tw complete turns.** Tighten locknut on stopscrew, making sure screw does not turn. Adjust cable (see above).

Elevator Valve Cable (1959 Models): *NOTE - If elevator valve cable is properly adjusted, there shoul be no free travel of elevator handle.* Operate elevator handle to be sure it is not restricted by air lines. If necessary, bend lines to obtain clearance. Loosen cable conduit clamp and disengage conduit from clip. With elevator handle on instrument panel pushed all the way forward, slide conduit forward at clamp until cable is slack at operating lever. *NOTE - In some cases it may be necessary to adjust cable at operating lever setscrew to obtain slack.* Pull conduit rearward until operating lever just moves, then push conduit forward until lever just stops. With conduit held in this position, tighten clamp. Secure conduit in clip and check elevator operation. *NOTE - There should be no free travel at elevator handle.*

Pressure Regulator (1959 Models): Connect Gauge J-7065 to high pressure tank valve, then operate engine, if necessary, to build up at least 200 lbs. in tank. Shut off engine and remove gauge. Disconnect front and rear height control valve exhaust lines at manual override valve, then connect Gauge J–7065 to the exhaust port at rear of manual override valve. *NOTE - Plug the front port as follows:*

Assemble a flare nut, ferrule and rubber seal onto a 1½" length of copper tubing. Seal ends of tube by crimping and folding, then install in the exhaust port. Pull elevator valve operating lever rearward and check gauge reading. Pressure should be 155–165 lbs. If not, adjust as follows: Remove rubber boot, hold elevator valve operating lever rearward and turn adjusting screw until reading on gauge is 155–165 lbs. *NOTE – Clockwise rotation of screw increas s air pressure.* Install rubber boot and remove gauge and special plug. Reinstall exhaust lines and check for leaks.

Carrying Height: *NOTE – It is recommended that rear carrying height be adjusted first whenever it is necessary to adjust both front and r ar carrying h ight. Wh n ch cking and adjusting, maintain a pr ssur of 175 lbs. of air in high pr ssur tank.*



CONTINUED ON NEXT PAGE

OLDSMOBILE NEW-MATIC RIDE (Continued)

Rear – Raise car and place floor stands under axle housing. Raise rear of car and hold in this position for at least 10 seconds, then release rear of car. The car should settle below normal height, then raise through valve action until it returns to normal height. Check distance from bottom edge of the piston to bottom edge of air spring diaphragm retainer with Gauge J–7156–1 or Magnetic Gauge J–7156–7. This checking must be done on the inboard side with the gauge parallel to centerline of air spring piston. If the dimension is not 1½" ± 1/16", adjust as follows: Loosen height control valve operating lever lock screw and turn the eccentric (located adjacent to lockscrew) to exhaust some of the air from air spring to lower car below normal carrying height. Slowly turn eccentric in opposite direction until car rises to proper carrying height. *CAUTION – Always raise the car for final carrying height adjustment.* Tighten lockscrew on operating lever and recheck carrying height. Repeat this procedure with opposite rear height valve, then recheck adjustment on both rear height control valves.

Front – Position a jack at front edge of front crossmember and raise the car. With both wheels in a straight ahead position, attach hooks of Gauge J–7156–2 (see illustration) to steering plain arms. *NOTE – Gauge cable must be installed so that its spring is beneath right hand lower control arm.* Position gauge blocks on underside of lower control arms in the flat between ball joint rivets and rubber bumper nut. The slanted edge of each block must face rear of car. Slowly lower floor jack. *NOTE – If the car is on a hoist, the front of the car must be raised at bumper or crossmember for approximately one minute, then release front end of car. The car should settle below normal height, then raise through valve action until it returns to normal height.* Check front carrying height between top edge of gauge cable and center of frame crossmember with Magnetic Gauge J–7736 or a steel rule. Distance should be 1" (1958); 1 19/32" (1959), plus or minus 1/16". If not, adjust height control valve in same manner as for rear height adjustment (see above). *NOTE - If eccentric has been turned for maximum adjustment, and the front carrying height is still incorrect, additional adjustment can be obtained by loosening locknut and bolt holding the lever to stabilizer bar. Radially reposition lever on stabilizer bar and tighten bolt and locknut.*

Front End Alignment: Same as for cars with conventional coil springs. See "Front Suspension" on Car Model pages.

OLDSMOBILE AIR SUSPENSION
(CHECKING FRONT CARRYING HEIGHT)

TROUBLE SHOOTING

On Or M r Air Springs G D wn (Will pump up in 10 minutes or less): Internal leak at high pressure check valve in the air filter. Internal exhaust leakage. External leak in system. A leak under any of the above causes plus a leak at the intake adapter check valve.

One or More Air Springs Go Down (Will not pump up): If one or two springs are down, check height control valve action. Compressor output low. Internal exhaust leakage. External leak in system. Restriction in high pressure system. To check for restriction in high pressure system, install Gauge J–7056 on high pressure tank. If pressure does not increase with engine at fast idle proceed as follows: Stop engine and disconnect high pressure hose at compressor. Disconnect line from tank to air filter assembly at the filter, then inject compressed air into high pressure hose. If air does not flow from air filter assembly, check for a restricted bronze filter or check valve in filter assembly. If air flows from filter, check for a restriction in high pressure line from air filter to manual override valve.

Car Will Not Elevate: Elevator valve cable out of adjustment. Compressor output low. External leakage in exhaust lines. Low regulated pressure. Internal leakage in elevator valve. Restricted exhaust lines.

Car Will Not Return From Elevated Position or Rides High: Elevator valve cable out of adjustment or binding. Restricted exhaust lines. Improper height control valve action. Incorrect carrying height.

Car Rides Hard: Incorrect carrying height. Bind in suspension members.

REMOVAL & INSTALLATION

AIR COMPRESSOR: Removal - Loosen compressor pulley nut and remove fan belts, then remove pulley nut from compressor shaft. Disconnect hoses from compressor, then position a small flat pan under power steering pump hoses and disconnect hoses from pump. Cap and plug fittings and hoses. Disconnect right and left rear auxiliary brackets, then loosen left rear brace-to-cylinder head stud so brace can be rotated out of way. Remove compressor mounting bolts and remove compressor and pump assembly.

Installation: Reverse removal procedure.

HEIGHT CONTROL VALVE (FRONT): Removal - Support front of car with jack stands placed under frame side rails so front wheels are hanging freely. Loosen all tubing connections at height control valve so all air pressure will be exhausted. *(NOTE* - Use a wrench to hold adaptors when loosening fittings). Disconnect link from height control lever, then carefully remove the tubing connections from height control valve. *(CAUTION - Use care as pressure may not be exhausted).* Tape ends of tubing, then remove height control valve.

Installation: Reverse removal procedure and note the following: Install low pressure line to medium length adaptor but do not tighten before installation of valve assembly. Check carrying height and adjust control valve eccentric as necessary (see "Adjustments").

HEIGHT CONTROL VALVE (REAR): R m val - Support rear of car with jack stands placed under frame side rails so rear wheels are hanging freely, then remove valve in same manner as for front height control valve (see above).

Installati n: Same as for front height control valves (see above).

ELEVATOR VALVE (1958): Rem val - Raise car and remove elevator valve baffle plate, then loosen five tubing connections to allow air to completely exhaust, and disconnect lines from valve. Loosen cable wire setscrew, then disconnect valve from bracket and remove.

Installation: Position valve on bracket at frame side rail and install and tighten bolts. Install air lines, using new "O" ring seals. Install cable wire to lever, then with lever pulled back against its stop, remove slack from cable wire and tighten setscrew. Lower car so springs are lower than normal but not supporting entire weight of car. Start engine and build pressure in system to approximately 100 lbs. Raise car and check all previously loosened fitting.

MANUAL OVERRIDE VALVE (1959): Rem val - Pull low pressure hose from valve, then loosen line connections at valve and allow all air to escape before disconnecting lines. Remove the two manual override valve attaching bolts and nuts and turn valve assembly so operating lever return spring is accessible. Disconnect return spring from lever and bracket, then loosen operating lever screw and slide lever from shaft. Remove valve assembly from car.

Installation: Reverse removal procedure and note the following: Tighten valve to bracket attaching bolts to 8 ft. lbs. Use new seals on line connections. Check all points for leakage, then adjust elevator valve cable.

AIR FILTER & CHECK VALVE (1959): Open drain cock and drain all water and oil from reservoir shell. Disconnect high pressure line at connector, then raise front of car and loosen lines at check valve retainer. Allow pressure to exhaust, then disconnect line. Remove three bracket-to-frame attaching bolts and block bracket away from frame. Remove three bracket-to-filter attaching bolts and remove air filter (with high pressure line) from car. Remove high pressure line from filter.

SEPARATOR (1958): Rem val - Loosen all air hoses and pipe fittings at separator and permit air to exhaust, then disconnect hoses and pipes from separator. Remove separator attaching bolts and remove separator.

Installation: Reverse removal procedure and operate engine to bring system up to operating pressure. Check for leakage at all connections.

AIR SPRING (FRONT): R m val - Support front of car at frame so weight of car is off front wheels, then remove wheel assembly. Loosen pressure line fitting at air spring and permit pressure to exhaust. Pull dust shield from strut seat and loosen strut seat setscrew almost to limit of threads. Disconnect shock absorber and stabilizer from lower control arm. Disconnect lower ball joint from steering knuckle using Tool J-6446 (same as for standard suspension). Disconnect air pressure line from air spring, then remove the 2 air spring mounting nuts and remove spring, piston and strut assembly. Tape lower end of strut to protect retainer groove and hardened end. Unscrew strut from

CONTINUED ON NEXT PAGE

OLDSMOBILE NEW-MATIC RIDE (C ntinu d)

piston, using a strap wrench to hold piston and a pipe wrench to turn strut. Pull retainer from air spring diaphragm pilot and remove piston.

Installati n: Clean strut and strut seat and lubricate seat with one ounce of special lubricant, Part No. 571035. Reverse the removal procedure and tighten strut to piston to 40-45 ft. lbs. and air spring nuts to 20-30 ft. lbs. Run engine to bring system up to operating pressure and leak test all fittings.

AIR SPRING (REAR): R m val - Support rear of car at frame so that weight is off rear wheels and support axle housing with jack stands, then remove wheel assembly. Loosen pressure line fitting at air spring and permit air pressure to exhaust. Pull dust shield from strut seat and loosen strut seat setscrew almost to limit of threads. Tape lower end of strut to protect retainer groove and hardened end. Unscrew piston strut from piston using a strap wrench to hold piston and a pipe wrench to loosen strut. Disconnect shock absorber at lower mounting, then remove pressure line from air spring and remove air spring mounting bolts. Push piston into air spring and remove piston strut. Remove piston and air spring as an assembly. Pull retainer for air spring pilot and remove piston.

Installation: Follow same procedure as for installation of front air spring (see above).

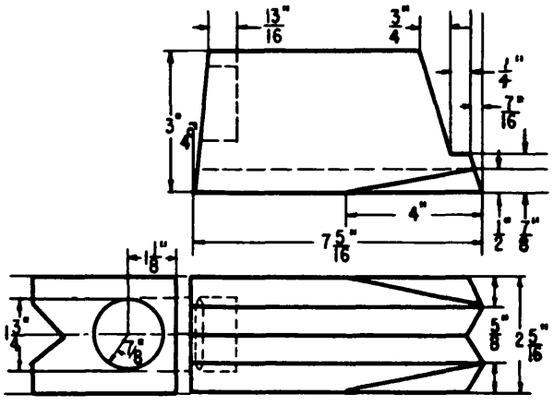
PONTIAC EVER LEVEL AIR RIDE

P ntiac (1958-59)

►CHANGES, CAUTIONS, CORRECTIONS

►*SERVICE CAUTIONS:* Before working under the car, jacking it up, or raising it on a hoist, the following precautions must be taken to prevent personal injury or damage to the car.

Raising Car (On a Jack): Raise car to its maximum height by starting engine and pulling out "Car Lift" knob located on underside of instrument panel to left of steering column before jacking. After car fully raised, shut engine off, then proceed with jacking the car. *NOTE* - Car can be returned to its normal riding level by pushing in "Car Lift" knob.



Raising Car (On a H ist): Always use jack stands under outer ends of axle or frame when supporting air ride car on a hoist.

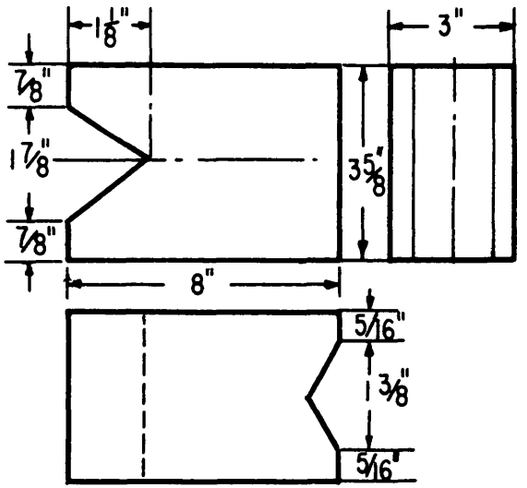
W rking Und r Car: Always place jacks under an air ride car before using a creeper as a precaution in case air should be exhausted from system.

►*TOWING THE CAR:* **Air Ride System Operating** - Pull out "Car Lift" knob and raise car to maximum height before towing.

Air Rid Syst m N t Op rating - Raise end of car (which will ride on the ground), using jack or hoist (see above) until wheels just begin to leave ground. *(CAUTION - Do not rais car furth r than necessary since bumper fac plat on opposit nd will be against ground).* Block car with safety stands, then insert blocks, Tool J-7299 between lower control arm and frame at front, Tool J-7315 between frame and axle at rear. If blocks are to placed at front (car being towed with front end on ground), these blocks must be between control arm rubber bumper and bumper pad on frame. Place bottom end over bumper first, then index "V" groove of block against upper end of steering knuckle to hold top of block in position. Rubber bumper will keep lower end of block in place. If blocks are to be placed at rear, position blocks so "V" notch at top is indexed with and centered on rubber bumper. *(CAUTION* - If block is positioned too far forward, it will bear against air cylinder retaining bolt). Remove safety stands and carefully lower car making sure blocks remain in position. Raise opposite end of car for towing. *CAUTION - Tow car cautiously as sharp bumps can result in s rv r damag t car.*

►*1958 TWO CYYLINDER AIR COMPRESSOR HEADREPLACEMENT CAUTION:* When one or both cylinder heads are replaced, install Spacer Gasket, Part No. 5549900, in addition to regular gasket, Part No. 5540189. Before replacing a complete air compressor, install the new spacer gasket under both cylinder heads.

PONTIAC FRONT TOWING BLOCKS



►*1958-59 AIR COMPRESSOR VENT FILTER SCREEN REMOVAL NOTE (TO DECREASE "COKING"):* Remove and discard screen whenever pulley nut is removed.

DESCRIPTION: *NOTE - 1958 and 1959 air suspension systems are similar, however, location of circuits and some of the components are different.* These systems consist of four rubber air springs, air compressor, height control valves, manual valve, and air reservoir tank. Operation is automatic and the car is maintained at its normal height above road level under varying load conditions. A "Car-Lift" knob on instrument panel is provided to raise car above rebound stops for tire changing or for additional road clearance. Basic components of systems are the same for 1958 and 1959 except as indicated below.

Air Compressor (1958-Early 1959): Single stage, two cylinder, reciprocating type mounted either integrally with power steering pump or as a separate unit. Lubrication for these units is obtained from power steering pump reservoir or from separate compressor oil reservoir.

Air Compressor (Late 1959): Single stage, single cylinder, reciprocating type mounted on front of engine and driven by either power steering pump belt or by a separate belt. This unit is lubricated by engine oil under pressure from engine main oil gallery.

Air R s rvoir: High pressure air reservoir tank is mounted in right front fender compartment and is provided with inlet and outlet openings at the top and a drain valve at bottom. A valve at inlet opening permits filling system from an outside source.

PONTIAC REAR TOWING BLOCKS

Manual Valve: Mounted on outrigger at left side (1958); right side (1959) side of frame back of front wheel. This valve contains a pressure regulator which maintains a pressure of 125-135 lbs. (1958); 130-140 lbs. (1959) when car is moving or a pressure of 145 lbs. (1958); 150-160 lbs. (1959) when car is standing. A manually operated "override" valve controlled by "Car Lift" knob in drivers compartment provides regulated air pressure to air spring to raise car body above normal operating level.

Air Pressure Relief Valve: This valve is located in the lower of two "tees" attached to frame near left (1958); right (1959) rear height control valve. The purpose of this valve is to prevent reservoir pressure (approximately 250 lbs.) from reaching air springs in the event of manual valve failure. Relief valve opens at approximately 165-175 lbs.

►*HEIGHT CONTROL VALVE NOTE: 1958 and 1959 height control valves are different types.*

Height Control Valves: There are three height control valves; one at the front and two at the rear. The front valve is mounted on the frame front crossmember and its operating link is connected to a clamp on the stabilizer shaft. The rear control valves are mounted on the rear

CONTINUED ON NEXT PAGE

PONTIAC EVER LEVEL AIR RIDE (Continued)

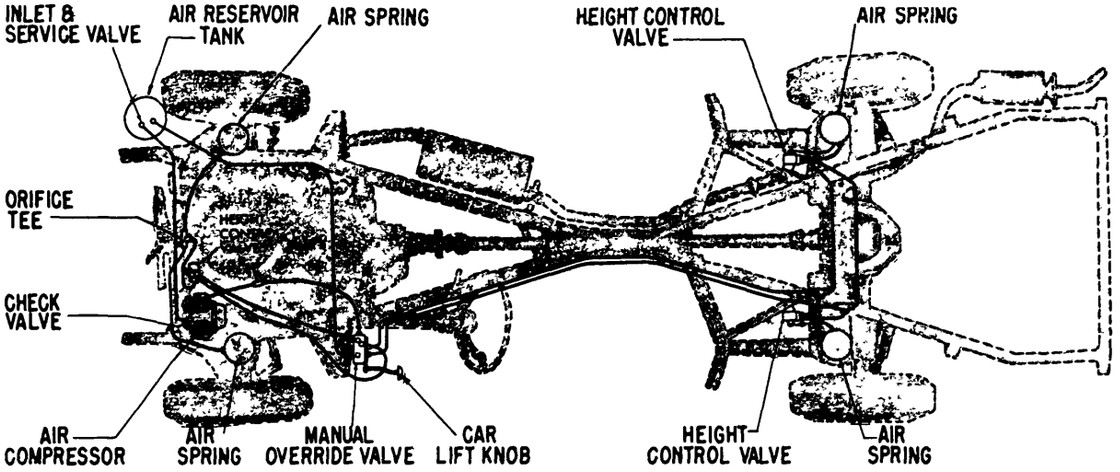
lower control arm brackets and are operated by links to the lower control arms. These valves control the car height by controlling the flow of air in or out of the individual air springs.

Air Springs: Each air spring consists of a metal cylinder, closed at the upper end and sealed at the lower end by a rubber diaphragm, making an air tight compartment. Each spring rides on a piston attached to a lower control arm in a manner to cause the piston to bear on the center of the air spring diaphragm.

LUBRICATION: Air Compressor (Two Cylinder) - *NOTE - It is not necessary to change lubricant in air compressor unless it is removed for repairs.* Check fluid in reservoir (or in power steering reservoir if so equipped) every 2,000 miles and add special fluid, Part No. 532186, as necessary to bring level up to "Full" mark on indicator.

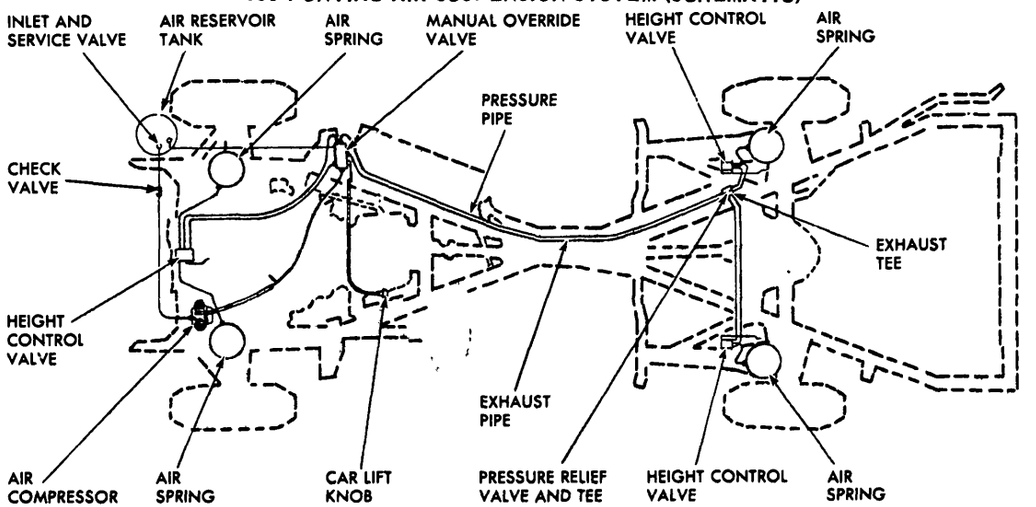
Single Cylinder: This compressor is lubricated by a line from engine oiling system and special lubricating procedures are not required.

DRAINING AIR RESERVOIR TANK: Every 2000 miles, open the drain valve at bottom of reservoir and drain sediment.



VALVE CLEANING: Clean the Manual Control and Leveling Valves every 25,000 miles as follows:

Manual Valve: Remove valve from car, then insert temporary plugs in all openings. Clean valve exterior with solvent and blow dry with air. Remove intake filter and retainer assembly. Remove and discard the "O" ring. Clean filter in solvent or replace filter. Install retainer, using a new "O" ring, and tighten to 45-55 inch-pounds. *(NOTE* - Use shim stock or suitable sleeve over retainer threads to prevent damage to "O" ring when installing). Remove exhaust filter plate and gaskets and discard gaskets. Cover valve body opening while cleaning parts. Clean plate and retainer in solvent and blow dry with air. Install plate and new gaskets and secure in valve body with fitting tightened to 5-8 inch-pounds. Check manual valve lever and spring, then install assembly on the car.



Height Control Valves: Remove control valve from car, then insert temporary plugs in three pipe adapters. Clean exterior of valve with solvent and blow dry with air. *(CAUTION - Do not use pipe plugs in the adapters).* Remove three adapters and discard the "O" rings. *(NOTE* - Hold intake valve stem firmly with open end wrench while removing intake adapter, do not remove intake valve). Remove temporary plugs, then clean adapters in solvent and blow dry with air. Install new screens. Install new "O" rings on intake valve stem and exhaust adapters using a suitable sleeve to prevent damage to "O" rings. Check tightness of intake valve stem which should be 12-15 inch-pounds. Apply a film of SAE 20 oil to "O" rings and install adapters. Tighten to 12-15 inch-pounds.

ADJUSTMENT

ADJUSTMENTS: Manual Valv - There are no adjustments within the manual valve. If valve has been removed and reinstalled or there is evidence the sliding valve (double acting) is not seating properly (indicated by low air pressure at height control valves), make sure stop screw in the override lever contacts flat on lever spring bracket when "Car Lift" knob is in the closed position.

1958 PONTIAC AIR SUSPENSION SYSTEM (SCHEMATIC)

1959 PONTIAC AIR SUSPENSION SYSTEM (SCHEMATIC)

Trim Height: Run engine 3-5 minutes to insure 145 lbs. pressure in reservoir tank, then check and adjust trim height as follows:

1958 MODELS

Front - Check distance between upper end of rubber rebound bumper and contact surface on frame crossmember. This distance should be 3½ - 3¾" (all models). To adjust, loosen one control link clamp U-bolt nut and rotate clamp on stabilizer shaft as required to obtain the proper trim height. Tighten the nut securely.

Rear - Check distance (vertically) between top of rear axle housing and lower side of frame crossmember. This distance should be 4" - 4¼" (Exc. Station Wagon); 4½" - 4¾" (Station Wagon). Adjust by rotating height control valve operating arm eccentric bolt as necessary to obtain correct trim height.

1959 MODELS

Front – Check distance between frame and rear top surface of lower control arm. This distance should be 2 7/8". To adjust, loosen one control link clamp U-bolt nut and rotate clamp on stabilizer shaft as required. Tighten nut.

Rear – Check distance (vertically) between frame bumper bracket beside rubber bumper and axle housing. This distance should be 4 1/8" (all models). To adjust, loosen height control lever retaining screw, then turn cam with a screwdriver or box end wrench, then tighten retaining screw.

Front End Adjustment: Same as for cars with conventional coil springs. *See "Front Suspension" on Car Mod l pag .*

Compressor Belt: Adjust belt tension to 50 ft. lbs., using

CONTINUED ON NEXT PAGE

PONTIAC EVER LEVEL AIR RIDE (C ntinued)

torque wrench in square hole provided in compressor front support (rubber mounted compressor). On rigid mounted compressors, apply a spring scale midway between crankshaft and compressor pulleys and adjust idler pulley until deflection in belt is 1/4" with a 6 lbs. pull.

Manual Valv C ntr l Cabl : *(NOTE* - There is no adjustment within manual valve. If manual valve has been removed and reinstalled or there is evidence the sliding double-acting valve is not seating properly indicated by low pressure at height control valves, make sure stopscrew in override lever contacts flat on lever spring bracket when car lift knob is in closed position). If stopscrew does not contact bracket, loosen control cable clampscrew, then move cable to permit screw to contact bracket, and tighten clampscrew. *(CAUTION - Stopscr w must not b adjusted since it is factory set to pr v nt l v r ov rriding shaft of cam when valve is clos d).*

TROUBLE SHOOTING

N Air In Syst m: Compressor drive belt slipping or broken. Check valve plugged or stuck open preventing air flow to tank or permitting leak back from tank. Ruptured or plugged hose or pipe between compressor and reservoir tank or between tank and manual valve. Leakage at tank service valve or pipe connections. Manual valve diaphragm ruptured. Manual valve sliding valve stuck in neutral position or defective. Manual valve lever retaining screw loose. Manual valve control cable or lever stopscrew out of adjustment. Plugged filter in manual valve inlet retainer. Compressor output below normal, broken rings or reed intake valve.

Car Ab v Trim Height (Will not come down): Shipping or towing block in place. Sliding valve stuck against exhaust port in plate of manual valve or port is plugged. Intake valve cores in all height control valves fail to close. Exhaust valve cores in all height control valves fail to open. Plugged orifice tee at front, and/or exhaust tee at rear.

Fr nt f Car D wn r L w r Than Specified Trim Height: Front height control valve not properly adjusted. Plugged intake valve in front height control valve. Height control valve adapter screens plugged. Leak between air spring diaphragm and piston. Leak at pipe connections. Control link clamp loose on front stabilizer shaft.

Fr nt f Car Can b Rais d To Override, Then Not L w red: Plugged orifice tee. Intake valve core in front height control valve fails to close. Exhaust valve core in front height control valve fails to open.

R ar f Car D wn or L wer Than Specified Trim Height: Rear height control valves not properly adjusted. Plugged intake valves in height control valve. Leak at crimp of air spring cylinder.

R ar of Car Can b Raised To Override, Then Not Low r d: Plugged exhaust tee at rear. Intake valve cores in both rear height control valves fail to open. Exhaust valve cores in both rear height control valves fail to open.

On Sid of Car Low r Than Oth r Sid : Rear height control valves not properly adjusted. Plugged or defective intake or exhaust valve at one height control valve.

On R ar Spring High, Opp sit Diag nal Fr nt Spring Low: Orifice in rear height control valve exhaust adapter plugged. Intake valve core in rear height control valve fails to close. Exhaust valve core in rear height control valve fails to open. Intake and exhaust pipes to rear height control valve crossed.

Car Rolls: Orifice tee at front not restricting flow of air between springs.

Oil In System: Vent passage in compressor crankshaft and pulley nut plugged, permitting piston ring blow-by.

REMOVAL & INSTALLATION

AIR COMPRESSOR: Proceed as follows for the various models:

1958 Models (Removal) - Disconnect air hoses at compressor. On power steering cars, drain oil from reservoir, then disconnect hoses from unions at rear of steering pump and cap the fittings. Loosen adjusting strap bolts (early cars), or idler pulley (later cars) and remove drive belt, then remove compressor.

Installation - Reverse removal procedures and note the following: If compressor is rubber mounted, do not tighten mounting bolts until after belt tension has been adjusted.

1959 Models (Removal, Two Cylinder Compressor) - Disconnect air hoses at compressor, then disconnect two hoses at rear of power steering pump and cap openings to prevent oil from draining. Release tension on drive belt by loosening idler pulley bracket bolts. Remove belt, then remove compressor and power steer-pump assembly.

Installation - Reverse removal procedure making sure that any spacers are installed in same location from which they were removed.

1959 Models (Removal, One Cylinder Compressor) - Disconnect hoses from compressor, then loosen idler pulley adjusting bolts and remove drive belt. Disconnect oil pressure pipe from compressor rear bearing cover. Disconnect oil drain pipe from side of compressor (other end of pipe connects to long hollow fuel pump attaching bolt). Loosen compressor mounting bracket brace bolt at manifold, then remove compressor from bracket. *NOTE - It may be necessary to remove fuel filter before removing compressor.*

Installation - Reverse removal procedures.

HEIGHT CONTROL VALVE (FRONT): Removal - Disconnect link from clamp at front stabilizer shaft, then remove pipes from valve adapters (tag pipes to insure correct connection when installing). Remove bolt and screw holding valve to mounting bracket or two valve bracket-to-frame attaching bolts and remove valve.

Installation: Reverse removal procedure and tighten pipe nuts to 5-10 ft. lbs. *CAUTION - Do not overtighten pipe nuts.*

HEIGHT CONTROL VALVE (REAR): Removal - Disconnect operating lever from link, then disconnect pipes from valve adapters (tag pipes to insure correct connection when installing). Remove valve to bracket attaching bolts and remove valve.

Installation: Reverse removal procedure and tighten pipe nuts to 5-10 ft. lbs. *CAUTION - Do not ov rtight n pipe nuts.*

MANUAL VALVE: R m val - Remove clamp securing control wire to bracket, then disconnect the high pressure and exhaust pipes at manual valve. Remove bolt securing manual valve to frame outrigger and remove valve.

Installation: Reverse removal procedure and adjust valve control cable (see "Adjustment" above).

RESERVOIR TANK: Removal - Discharge pressure from tank, then disconnect inlet and outlet pipes. Remove fender and tank assembly from car, then remove tank from fender.

Installation: Reverse removal procedure. If inlet valve is replaced, use a new "0" ring between tank and valve nut.

AIR SPRING (FRONT): Removal - Place jack stands under forward end of each frame side rail, then raise front end of car (on side from which spring is to be removed), a sufficient distance to permit removal of wheel and tire. Disconnect pipe from air spring cylinder, then disconnect stabilizer shaft link from lower control arm. Remove shock absorber and remove nut from lower control arm ball stud. Force lower ball stud assembly off steering knuckle, using Tool J-6627. Swing steering knuckle assembly out to clear lower control arm and lower the control arm. Remove two air spring cylinder to frame attaching bolts and the nut securing cylinder to upper control arm bracket, then withdraw air spring assembly. Piston can be removed from lower control arm by removing attaching bolts and plate.

Installation: Secure air spring to frame with two bolts and to upper control arm bracket with nut, then connect pipe to air spring cylinder. Raise lower control arm and swing steering knuckle into place. Use a floor jack and raise lower control arm, making sure piston is properly centered in diaphragm. (Coat lip of diaphragm with silicone grease to aid assembly of head of piston into diaphragm). If necessary, use air pressure in air spring to facilitate seating of spring piston in diaphragm, or guide hole in diaphragm over pilot on head of piston with a heavy screwdriver. Secure ball stud with nut and tighten to 60-95 ft. lbs., then install cotter pin. Install shock absorber and connect stabilizer shaft link to lower control arm. Install wheel and lower car to floor. Adjust trim height (see above).

AIR SPRING (REAR): Removal - Disconnect height control valve link from lever, then raise rear end of car high enough to permit piston to clear diaphragm *(CAUTION* - Use care not to break rubber hose at rear axle housing cover). Remove piston to lower control arm attaching nut and self tapping screw and slide piston off control arm. Disconnect pipe from air spring cylinder, then remove two air spring cylinder to frame bolts and withdraw air spring assembly.

Installation: Reverse removal procedure and note the following: Tighten bolts to 20-35 ft. lbs. When installing piston, the self tapping screw must be toward rear. Align air spring with piston using shims as required (with car at proper trim height).

OVERHAUL

AIR COMPRESSOR: *S "Air Susp nsion Air Compr ssor"*

LEVELING VALVES & MANUAL VALVE: *Se "Air Suspension L veling & Manual Control Valv s"*

RAMBLER AIR SUSPENSION

Rambler (1958-60)

►*TOWING & HOISTING NOTE:* No special procedures are required when either towing or hoisting cars equipped with air suspension.

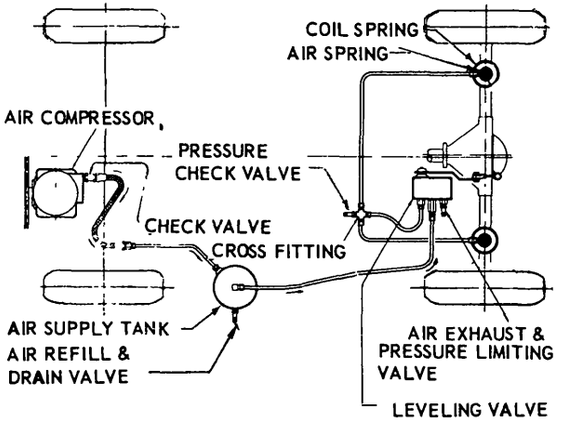
DESCRIPTION: The air suspension system consists of a neoprene air spring mounted within "low rate" conventional type coil springs on the rear axle assembly (front coil springs are not equipped with air suspension) a single cylinder air compressor, air reservoir, and a leveling valve. Operation of the system is automatic, maintaining the car at its normal height above the road under varying load conditions.

OPERATION: Basic components of the air suspension system operate as follows:

Air Compressor: Single cylinder reciprocating type rated at 1 cubic foot of air per minute at 150 lbs. pressure, at 50 MPH. The air compressor is belt driven by a double pulley on power steering pump (Series 20 & 80), and by a double pulley fan hub (Series 10). Oil is piped from engine lubricating system for compressor lubrication.

Air Reservoir: This is a 300 cubic inch capacity tank located under the left front fender. In addition to inlet and outlet fittings, the reservoir is equipped with a combination (Schrader type) refill and drain valve, located at bottom of tank, and an air filter.

L veling Valve: A single leveling valve located on car body at the rear, and connected to rear axle assembly by an adjustable link, controls the amount of air entering or leaving the two air springs. A delay or "dwell" feature included in leveling valve prevents leveling action during slight operating motions of car suspension system. This feature allows approximately 1/2" movement vertically in either direction from normal trim height before valve will open to admit or exhaust air. Operating height of car is controlled by adjustment of the leveling valve connecting link.



Air Springs: These assemblies mounted within the "low rate" conventional type coil springs consist of a neoprene air bag, an upper spring seat assembly (through which air is admitted to the air bag), and an air spring piston. A check valve at air spring outlet in the leveling valve prevents air pressure in air spring from dropping below approximately 18 lbs. pressure. This prevents air spring from being entirely deflated if body is jacked up.

LUBRICATION: Air Compressor - Oil from engine lubricating system is piped to the compressor and additional lubrication is not required.

DRAINING AIR RESERVOIR: Every 1000 miles, depress the Schrader type valve located at bottom of reservoir and allow trapped moisture to be exhausted.

AIR FILTER CLEANING: Remove air filter cover and clean air filter element every 2,000 miles.

ADJUSTMENTS: Trim Height - Measure distance between top of rear axle tube to the flat portion of top coil of spring. This distance must be 9 13/16" to 10 7/16" (sedan); 10 9/16" to 11 3/16" (station wagon). If adjustment is required, loosen eccentric bolt locknut on leveling valve arm and rotate eccentric bolt to move arm up or down until correct spring height is obtained.

RAMBLER AIR SUSPENSION SYSTEM (SCHEMATIC)

TROUBLE SHOOTING

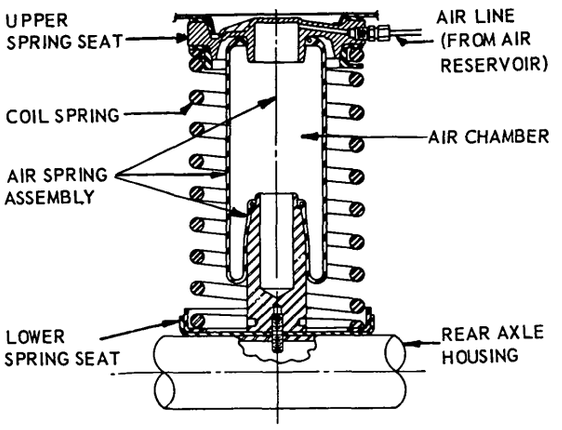
Loss Of Tank Pressure & Car Settles While Parked: Check for leakage at air springs, height control valve, or supply lines from valve to air spring.

Loss Of Tank Pressure & Car Stays At Trim Height While Parked: Leakage at compressor check valve. Leaking intake valve core in height control valve allowing air supply to air springs, which moves height control valve arm, to exhaust (this condition of cycling exhausts or lowers tank pressure to air spring pressure). Check for leakage at tank, fittings, or supply lines.

Slow Trimming: Check for low air reservoir pressure, leakage in lines or at valves, low compressor output, or for restrictions at all fittings.

Failure To Return To Within ½-1" Of Normal Trim Height: Check height control valve operation and adjustment. Check for inoperative intake or exhaust valve cores, restrictions in air exhaust or intake orifice fittings, or restrictions in air spring fittings and lines.

Hard Or Soft Ride: Check tire pressure, shock absorber operation, spring height, or for control valve operation.



REMOVAL & INSTALLATION

AIR COMPRESSOR: Removal - Discharge air pressure in system by opening drain valve on supply tank, then disconnect air line at compressor. Loosen drive belt and remove oil connections on compressor. Remove compressor from mounting flange and remove base plate and gasket.

Installation: Reverse removal procedure.

HEIGHT CONTROL VALVE: Removal - Raise rear of car on a hoist or jack. Drain air from system by opening drain valve on supply tank, then disconnect and remove height control valve to rear axle link Remove air exhaust and pressure limiting valve from height control valve, then disconnect air supply line. Disconnect air supply line from height control valve to air spring cross "tee". Remove height control valve from bracket, noting position of valve in relation to slotted hole in bracket.

Installati n: Reverse removal procedure and adjust height control valve. See "Adjustments" above.

RAMBLER AIR SPRING ASSEMBLY

AIR SPRINGS: Removal - *(NOTE* - Height control valve lever arm to rear axle link must be removed whenever shock absorbers, coil springs, air springs, or rear axle are to be removed). Exhaust all air from system by opening drain valve on supply tank. *(NOTE* - Height control lever arm must be moved into exhaust position to completely exhaust air from spring and wired in that position whenever air springs are to be removed). Raise car on a hoist or jacks and remove height control valve to rear axle link. Disconnect air spring lines from each upper spring seat and the shock absorbers at their mounting bracket studs, then lower axle assembly. Coil spring, upper spring seat, and air spring may be removed as an assembly by using a spanner type wrench on the air spring piston to turn it out of the lower spring seat. Pry air spring from upper spring seat with a screwdriver blade. Pull air spring piston out as far as it will go, then place air spring on a bench with only the piston projecting over the edge. A sharp downward twist will remove piston from air spring.

Installation: Invert small end of air spring by turning it inward, apply liquid soap to air spring and piston and insert piston into inverted end of air spring. Place air spring assembly and piston into an arbor press with piston on the bottom, then use Tool J-7480 and J-872-5 in press so bead ring of air spring is positioned over lip end of air piston (Pilot of installing tool is indexed into position and the lip of the tool contacts bead area). Install air spring on upper spring seat by assembling both spring seats and coil spring, then install on axle assembly. Apply liquid soap solution to seat and air spring and index upper bead with the upper seat; raise axle assembly and pump air into air spring to seat the bead. Complete installation by reversing removal procedure.

OVERHAUL

AIR COMPRESSOR: *See "Air Suspension Compressors"*

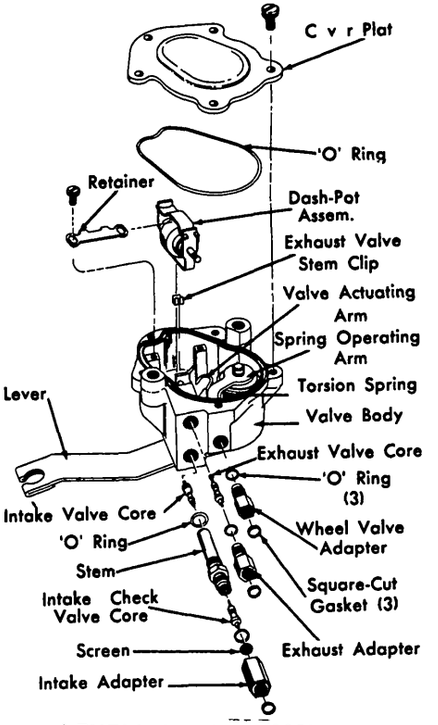
LEVELING VALVE: S *"Air Suspension Leveling & Manual Valves"*

G.M. AIR SUSPENSION VALVES

Buick (1958-59)
Cadillac (1958-60)
Oldsmobil (1958-59)
Pontiac (1958-59)
Rambler (1958-60)

►*RAMBLER NOTE: Manual valve not used on Rambler models.*

DESCRIPTION: L v ling Valve (1958 Buick, Cadillac, Oldsmobil , P ntiac & 1958-60 Rambler) - Leveling valves on all models are similar in design except for shape of operating lever and slight differences in valve assemblies. Dashpots, built into valve housing, are used on all Cadillac models and on early Pontiac models (not used on later Pontiac models).



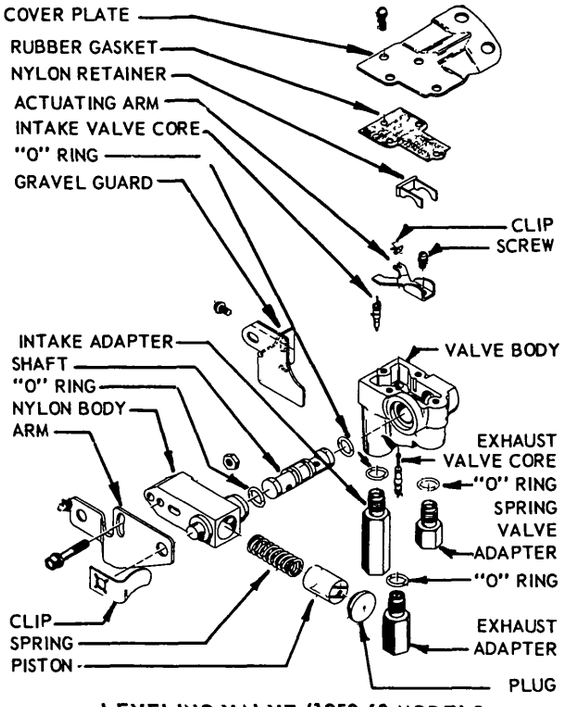
L v ling Valv (1959 Buick, Cadillac, Oldsmobile, & P ntiac): Valve design is changed from type used on 1958 models and overhaul procedures are different. Valves for all 1959 models are similar in design except for shape of operating lever and slight differences in valve assemblies.

Lev ling Valv (1960 Cadillac): Rear leveling valves are same as used on 1959 Cadillac. Front leveling valve is similar in design to 1959 models except that it utilizes two port adapters (one to each wheel suspension bellows) in place of the single valve adapter previously used. A rubber umbrella-type check valve core is used in intake valve adapter in each leveling valve instead of tire-type core previously used.

Manual Valv (All Mod ls, Exc. Rambler): Cable operated valve and pressure regulator assembly. Valve assembly design is similar on all models except for mounting and control lever.

OPERATION: Height C ntr l Valve - As car loads, height valve body lowers and valve operating lever moves upward in relation to valve causing valve actuating arm to open intake valve permitting air to enter and pass through to air spring. As air spring fills and raises car body to normal level, valve operating lever moves down allowing intake valve to close. An intake check valve prevents air returning into intake pipe from control valve if reservoir tank is low in pressure. As car unloads, air springs tend to expand, raising car body and in turn rotating operating lever below its normal position. This causes actuating arm to open exhaust valve permitting air to exhaust from air spring, through the control valve and return to the compressor. Air will exhaust from spring until operating lever assumes its normal position and closes the exhaust valve. A lash band of approximately 3° prevents hunting in normal operation.

Manual Valve: The regulator controls air pressure from reservoir tank to height control valves and springs. When pressure on regulator diaphragm builds to its designed pressure, the spring pressure is overcome permitting valve to close against its seat in valve body. As air pressure between regulator and height control valve drops, the spring expands, opening the valve and the pressure build-up cycle repeats. The override section of valve supplies regulated air pressure to air springs when it is desired to raise car body above its operating level. In normal operation, one end of two-way sliding valve is firmly seated against valve body



LEVELING VALVE (1958 MODELS & 1959-60 RAMBLER)

preventing regulated air from entering exhaust lines and allowing free air flow in exhaust side of system through the exhaust port to air compressor. When override lever is raised by pulling out on knob on instrument panel, the sliding valve moves off its seat in valve body and at the same time closes the exhaust port. This permits regulated air to reverse flow through exhaust lines, height control valves, and into springs, increasing pressure in the air springs and raising the car.

REMOVAL & INSTALLATION: *See individual car model air suspension data.*

LEVELING VALVE OVERHAUL
1958 MODELS & 1959-60 RAMBLER

DISASSEMBLY: *(CAUTION - Location and number of screens used in leveling valves is different for individual models. Care must be taken at disassembly to note location of screens for proper installation).* Clean exterior of height control valve with water and brush (do not use solvent). Remove valve cover screws and lockwashers, then remove cover and "0" ring. On leveling valves having a dashpot, remove dashpot retainer screws and carefully disengage dashpot shaft from slot in valve actuating arm. Rotate dashpot slightly and remove. On all valves, remove high pressure (longest) adaptor, then remove high pressure stem and "0" rings. Remove high pressure Schrader valve front stem using Tool J-6888. Remove low pressure adaptor (medium length) and "0" ring from valve body. *(NOTE - If low pressure Schrader valve is to be removed, remove copper*

LEVELING VALVE (1959-60 MODELS EXCEPT RAMBLER)

clip from end of valve, using care to prevent damage to clip so it can be reused, then remove Schrader valve using Tool J-6888. Remove air spring adapter (shortest) and "0" ring from valve body. Leveling valve cannot be dismantled further as actuating lever, torsion spring, and outside operating lever are pressed into the shaft and are not serviced separately. Valve shaft seal is vulcanized to shaft and to housing and cannot be removed. *(CAUTION - Do not force actuating lever as this will damage vulcanized shaft seal).*

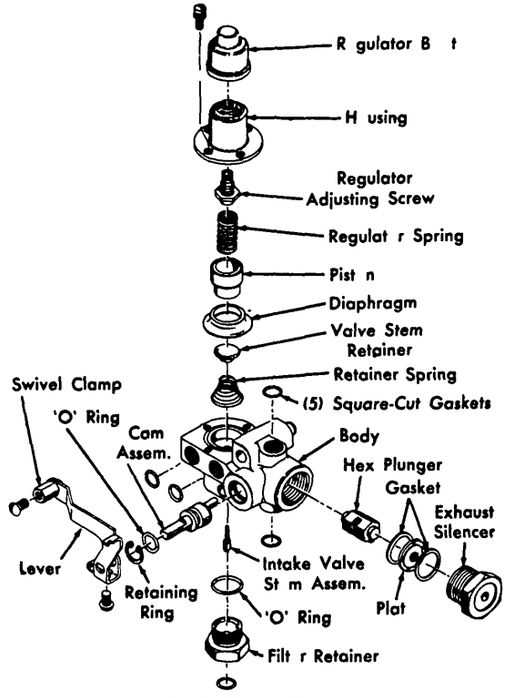
CLEANING & INSPECTION: Clean interior of valve body with compressed air (do not use solvent or gasoline). Clean valve adaptors with solvent and compressed air. Inspect high and low pressure adaptors to be sure orifices are not plugged. Inspect screens. If plugged and cannot be cleaned, replace screen (if part of adaptor assembly, replace adaptor). Inspect valve cores for damaged sealing surfaces. Discard all "0" rings.

REASSEMBLY: *(CAUTION - Install all screens in same location from which they were removed at disassembly).* Clamp hex head of valve stem in vise, using soft jaws. Install both intake and check valve cores in stem with Tool J-6888, tightening each to 2½-3 inch lbs. (see illustration for valve identification). Install new "0" ring under hex head of valve stem using a suitable sleeve if available, to prevent damage to "0" ring. Start stem by hand into valve body and tighten to 12-51 inch lbs. Install exhaust valve core in body using Tool J-6888 and tighten to 2½-3 inch lbs. Spread ears of clip and as-

CONTINUED ON NEXT PAGE

G.M. AIR SUSPENSION VALVES (C ntinu d)

semble immediately behind exhaust valve stem head. Brace valve stem with screwdriver and, using Tongnose pliers, pinch ears together. *(NOTE* - Do not install clip too tightly as it must rotate freely on valve stem). Install new "0" ring on each adaptor, using suitable sleeve to prevent damage to seal. Apply film of SAE 20 oil on "0" rings to aid in air-tight seal. Install intake adaptor and exhaust adaptor, then install air spring adaptor and tighten all adaptors to 12-15 inch lbs. *(NOTE - Be sure and install screens in same locations noted at disassembly).* On valves with a dashpot, place dashpot into valve body and engage recess of dashpot shaft in slot of valve actuating arm. Retainer tabs must hold dashpot firmly against two shoulders of valve body recess. If necessary, manually operate lever assembly slightly to allow dashpot body to seat against shoulders. *(CAUTION* - Use care not to damage exhaust valve stem). Install retaining screws and tighten. Check position of intake and exhaust valve cores (not intake check valve) to be assured they open at correct time as follows: Connect hose, J-7143, to air pressure line and reduce pressure to 10-20 lbs. (Do not exceed 20 lbs.). Connect other end of hose tightly to exhaust adaptor. Place .049" end of gauge, J-7148-1 between middle ear of actuating arm and its stop opposite to valve cores. Insert wedge, Tool J-7148-2 between other side of arm middle ear and stop. Wedge should hold gauge, J-7148-1 so it will not fall out. Press slightly against exhaust core at seal seat using a thin screwdriver. A slight air leakage should be heard. Remove wedge and gauge. Place .053" end of gauge, J-7148-1 between middle ear of actuating arm and stop opposite to valve cores. Insert wedge on other side of arm and again press lightly against core seal seat. This time no air leakage should be heard. If leakage is heard in this test (with gauge and wedge still in place), bend upper ear of actuating arm slightly toward valve core seat using Tool J-7148-3. Press lightly once more against core and seal seat. If no leakage is heard, bending of arm was sufficient; however, if leakage still exists, bend ear a little more. Remove wedge and gauge and reverse their positions placing .049" gauge between actuating arm middle ear and stop on valve core side. Transfer air hose from exhaust to intake adaptor and increase air pressure to 50-80 lbs. Slight leakage should be heard and, if not, bend lower ear toward intake valve core until leakage is heard. Remove wedge, insert .053" end of gauge and replace wedge in same location from which it was removed. No air leakage should be heard; however, if leakage does exist, bend lower ear away from valve core with Tool J-7148-3 just enough to stop it. Place new "0" ring in valve body groove and apply a light coating of SAE 20 oil. Install cover and tighten screws to 20-25 inch lbs. Check for leakage, then remove air hose.



LEVELING VALVE OVERHAUL 1959-60 MODELS (EXC. RAMBLER)

DISASSEMBLY: Remove cover plate and discard gasket, then remove intake and exhaust valve adapters and wheel valve adapter. Discard the "O" rings. *NOTE – Do not remov exhaust or intake valve cor s unless d f ctiv . If defectiv , remov nylon r tain r, valve actuating arm r tainer screw, lockwasher, and actuating arm.* Remove exhaust valve core clip and then remove valve core from outer side of valve body, using Core Remover & Installer, Tool J–6888. *NOTE – exhaust valve core is the longer core.* Remove intake valve core from inner side of valve body with Tool J–6888. Remove leveling valve arm assembly by pulling assembly away from valve body. Discard the "O" ring. Remove screw securing gravel guard to body and remove guard. Remove spring clip from arm body by prying off with a screwdriver. *CAUTION – Be careful not to break plastic body or pivot point.* Remove rubber plug end from end of plastic body, then depress spring loaded piston (use Tool J–7796, Cadillac; J–8424, Oldsmobile to depress piston), and remove shaft from body. *CAUTION – Use care when depressing piston as it is spring loaded and could be ejected with great force.* Remove piston and spring from plastic body, then discard shaft "O" ring seals. Remove adjusting bolt from arm assembly and remove arm.

INSPECTION: Inspect all parts for defects or damage and replace as necessary. Clean all parts with solvent and dry with low pressure air.

REASSEMBLY: Use Valve Core Remover & Replacer, Tool J–6888 with a torque wrench, install both cores in valve body and tighten to 2½–3 inch lbs. *NOTE – Intake valve core is the shorter core and must be installed in smaller valve seat, inside valve body. The exhaust valve core must be installed in counterbored valve seat from outside the valve body.* Use a new "O" ring and install intake flow valve over intake valve core in valve body, then tighten to 12–15 inch lbs. Do not damage "O" ring. Install wheel valve adapter with a new "O" ring and tighten to 12–15 inch lbs., then install gravel guard on valve body. Reassemble leveling valve arm by reversing disassembly procedure, then lubricate arm spring with several drops of engine oil and install assembly in valve body, using a new "O" ring seal on arm shaft. Lubricate shaft bearing surfaces with petrolatum, then position arm shaft with slot up and install actuating arm so that tab with slotted end is under the exhaust stem core and install exhaust valve core clip. Install nylon retainer with radius over arm shaft and secure actuating arm with screw and lockwasher. *NOTE – Whenever intake or exhaust valve core is removed and replaced it is necessary to check adjustment of respective tabs on valve actuating arm.* Install new rubber gasket on valve body and install cover plate. Tighten retaining screws to 10–15 inch lbs. Check valve for leakage.

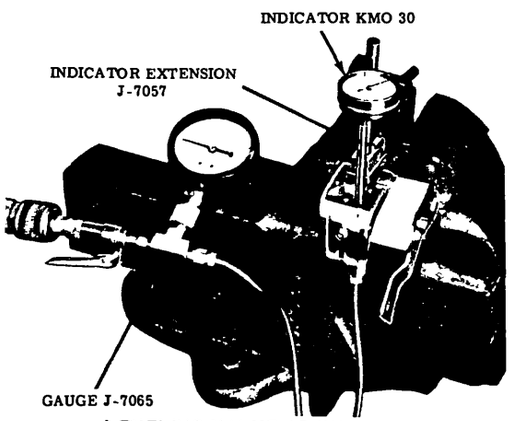
ADJUSTMENT: Cadillac – Remove leveling valve cover and rubber gasket, then remove wheel valve adapter and intake valve adapter. Fasten clamp portion of Dial Indicator Set, Tool J–8001, on leveling valve (see illustration). Use a thin flat washer to protect machined surface of leveling valve, and to hold down nylon retainer. Place clamp and leveling valve in a vise, then remove knob from indicator and replace with Extension, Tool J–7057. Install dial indicator assembly on clamp and position extension over intake valve core. Move leveling valve arm downward until actuating arm bottoms, then move dial indicator assembly down until light tension is obtained against actuating arm. Set dial indicator to zero, then insert a 1/8" drift punch into intake valve opening from bottom and lightly depress valve core to fully closed position. Record reading on dial indicator (this reading indicates intake valve travel). While still holding intake valve core in closed position with drift punch, set dial indicator to zero and raise leveling valve arm until exhaust valve core starts to unseat. Record dial indicator reading at this point. *NOTE – This distance is the "dead band area" and is the distance the actuating arm trav ls from the time the intake valv closes until exhaust valve begins to open.* After "dead band area" distance has been determined, continue raising leveling valve arm upward until actuating arm contacts nylon retainer, and note indicator reading. Remove drift punch. Subtract "dead band area" distance reading from the final reading taken to determine exhaust valve core travel. *NOTE – Exhaust and intake valve core travel should be a minimum of .025". Any travel over .025" is allowable. The "dead band area" should be between .035–.050".* If any of the above travel distances are not within specifications, bend legs of actuating arm, using Bending Tool J–7183–2, as follows: To increase intake valve core travel, bend intake leg of actuating arm down slightly. To increase exhaust valve core travel, bend exhaust leg of actuating arm up slightly. To increase "dead band area", bend leg of actuating arm corresponding to valve having the most travel. To decrease "dead band area", bend leg of actuating arm corresponding to valve having the least travel. *NOTE - If any adjustments are made, recheck all measurements.*

LIFT VALVE (TYPICAL)

Buick: With valve cover, exhaust valve clip, and intake fitting removed from valve body, mount Dial Indicator, KMO–30–B, Sleeve, KMO–30–K, and Support J–1013 on machined cover surface of valve body so indicator stem contacts the exhaust valve core. Set indicator to zero and move valve lever to raise core. *NOTE – Make sure that plastic stop is held down to insure*

CONTINUED ON NEXT PAGE

G.M. AIR SUSPENSION VALVES (C ntinued)

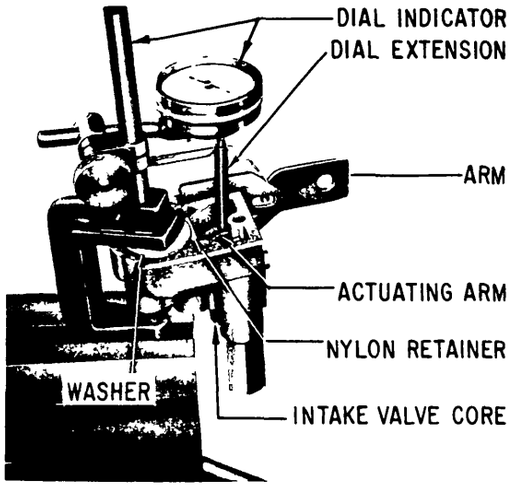


proper reading. Total travel of exhaust core should be .010—.015". If core travel is not correct, bend lever ear a very slight amount with Bending Tool, J—7148—3. Recheck valve travel and adjust as necessary. Install valve core clip and avoid bending core stem. Install long extension, J—5339, on dial indicator, then install intake fitting **in air spring fitting opening** in valve body. *NOTE — Air spring fitting is farthest from intake core.* Mount dial indicator assembly on top of intake fitting and check intake core travel as follows: Set dial indicator to zero and move lever to raise core. Total travel of core should be .025—.030". If core travel is not correct, bend the lever ear, using Bending Tool J—7148—3. Recheck valve core travel and adjust as necessary. Remove intake fitting from air spring fitting opening in valve body, then replace cover using a new gasket. Install air spring fitting in proper opening and install intake fitting.

Oldsmobil : Remove valve cover, then remove air spring valve adapter (two adapters on front height valve). Remove small contact from Dial Indicator, KMO—30 and replace with Extension J—7057, then attach dial indicator to height control valve (see illustration), and mount the assembly in a vise. Connect Gauge J—7065 to intake adapter and attach air supply line to gauge. Position Indicator Extension J—7057 so it contacts and exerts pressure on actuating arm directly above intake valve core. Raise operating lever until it is horizontal, then move lever down **until actuating y k stops m ving** (air should flow through intake adapter). Set dial indicator to zero. Slowly raise operating lever until intake valve closes (air just stops flowing) and note reading on indicator which should be .025—.060". If reading is not within specifications, bend intake arm of yoke with Bending Tool J—7148—3, bend arm away from valve to decrease reading, toward valve to increase reading. Recheck valve travel adjustment. To check "dead band area", raise operating lever until yoke arm just starts to open exhaust valve, then set dial indicator to zero. Slowly lower operating arm until air just starts flowing and note reading on indicator. Travel should be .030—.040". To adjust "dead band area", bend yoke exhaust arm with Tool J—7148—3. Bend arm away from exhaust valve to decrease reading, bend arm toward exhaust valve to increase reading. Recheck travel and adjust as necessary. Remove indicator assembly and install adapters, gasket and cover.

MANUAL VALVE OVERHAUL

ALL MODELS (EXC. RAMBLER)



DISASSEMBLY: On Cadillac, loosen lever retaining screw and remove lever. On other cars remove lever return spring, then loosen retaining screw and pull lever from shaft. If lever spring bracket attached to valve housing, remove three screws and remove bracket. Remove rubber boot, then remove remaining screw and

LEVELING VALVE ADJUSTMENT (EXCEPT OLDSMOBILE)

remove piston housing assembly. Withdraw diaphragm, piston and spring from piston housing. Remove filter retainer assembly and destroy "0" ring. While holding valve stem retainer firmly in place, unscrew valve stem from retainer with Tool J-7085. Destroy retainer. Remove cam retaining ring using Truarc pliers, then remove cam and destroy "0" ring. Remove exhaust fitting and withdraw plate, gasket, and sliding valve. Destroy gasket.

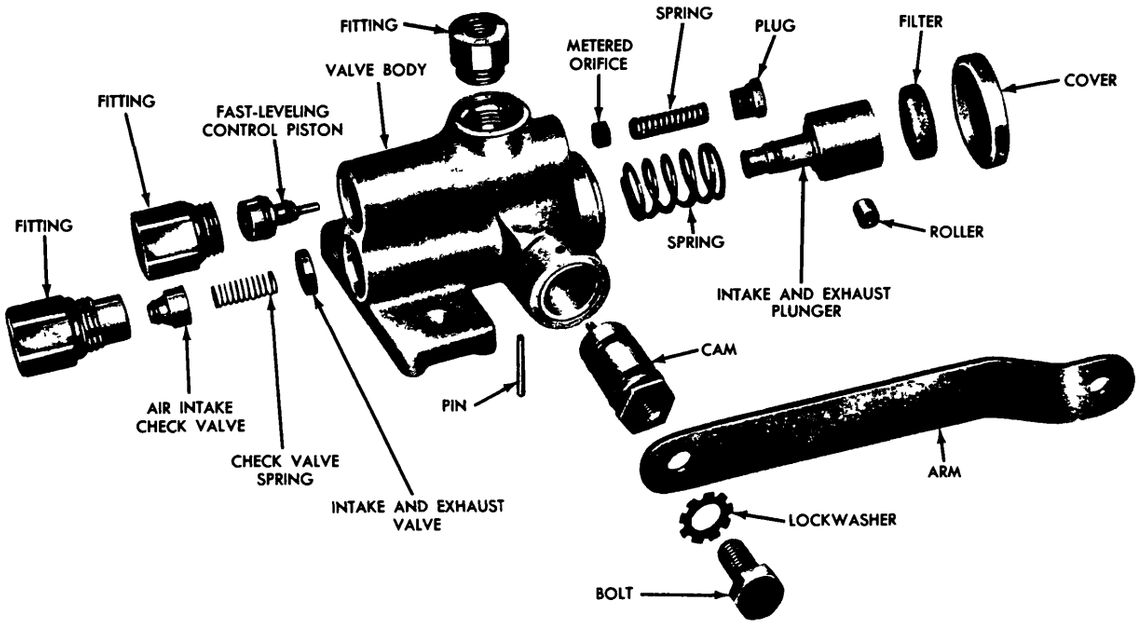
REASSEMBLY: Before reassembly clean all parts in solvent and blow dry with air. Replace all defective parts. Insert sliding valve into body with slot toward top (diaphragm side of body). Install new gasket, plate, second new gasket, and fitting into body. Tighten retainer to 45-55 inch lbs. Install new "0" ring into groove in cam and install into valve body with flat of shaft upward. Cam pin must enter slot of sliding valve. Install cam retaining ring using Truarc pliers. Assemble new valve stem retainer in small diameter end of retainer spring and insert assembly into valve body, large end of spring first. While holding retainer firmly in place, insert valve stem through intake port and screw stem carefully into retainer using Tool J-7085 *(NOTE* - Stem must be secure in retainer, but must not bottom since it will raise a small knob on rubber diaphragm side of retainer which may puncture diaphragm). Assemble new "0" ring on filter retainer. Using shim stock or suitable sleeve over retainer threads, install "0" ring. Apply film of SAE 20 oil on "0" ring and install filter retainer. Tighten to 45-55 inch lbs. Form a pocket in fabric side of new diaphragm with finger and place diaphragm, rubber side down, in groove in valve body. Insert regulator spring in piston. With regulator

LEVELING VALVE ADJUSTMENT (OLDSMOBILE)

screw turned as far as possible out of piston housing, slip spring and piston into housing. Make sure diaphragm is exactly centered and set piston, spring and housing assembly on diaphragm and body. Small end of piston must seat in diaphragm. Start housing attaching screw and lockwasher in hole nearest center of body. Complete reassembly by reversing disassembly procedure, then adjust pressure regulator for correct working pressure (see below).

PRESSURE REGULATOR ADJUSTMENT: With car on jack stands and air suspension system completely exhausted, disconnect high pressure line to front air springs on manual valve. Connect Air Ride Hose, J-7143 (make sure that "0" ring remains in seat in valve) to line fitting. Operate engine to replenish supply in air suspension system, then operate engine at slow idle to maintain air pressure. Depress service valve stem on end of hose, Tool J-7143 momentarily allowing air to escape, then check pressure at service valve end of hose, J-7143 using a suitable pressure gauge. Pressure in system should be 145 lbs. (Exc. Cadillac); 125 lbs. ± 5 lbs. (Cadillac Series 60 & 62); 150 lbs. ± 5 lbs. (Cadillac Series 75). If pressure not within limits, remove rubber boot from top of lift valve and rotate pressure regulator screw as necessary to bring pressure within specifications. *(NOTE* - After each adjustment, depress service valve in end of hose to allow regulator to operate before checking pressure). After completing adjustment, replace rubber boot, then turn off engine and exhaust all pressure in system. Remove hose, Tool J-7143, install a new "0" ring in valve seat and install front air line.

FORD & MERCURY AIR SUSPENSION VALVES



Ford (1958)
Mercury (1958)

►*OVERHAUL NOTE:* Solenoid Valve, Pressure Regulator Valve, T-Check Valve, and Restrictor Valve are not serviced and must be replaced with a new assembly if found to be faulty.

DESCRIPTION: These lever operated Leveling Valve assemblies consist of two separate valves; one controlling low air pressure for "slow-leveling" and the other controlling high pressure for "fast leveling". A lever, connected between valve cam and car body regulates the amount of air admitted to, or exhausted from, the air spring or springs (individual valves for each air spring at front of car, and a single valve for the two air springs at rear of car).

OPERATION: Slow-Leveling Control - Reservoir pressure at pressure regulator valve is reduced to 160 lbs., and is directed to leveling valve where it enters just above the air intake check valve. This pressure unseats check valve and enters above intake and exhaust valve. When leveling arm is moved upward by suspension arm or rear axle, the intake and exhaust plunger moves intake seat upward, allowing air pressure to flow around valve and metered orifice valve. Pressure flows through center of metered orifice valve, out of leveling valve, through T-check valve, and into air spring. When leveling valve arm is moved down, intake and exhaust plunger also moves down, opening the exhaust seat. Intake and exhaust valve closes off pressure supply to T-check valve. Pressure flows from the air spring through T-check valve, to leveling valve, and through center of metered orifice valve. This pressure then flows to intake and exhaust valve plunger, and exhausts through center of the plunger.

Fast-Leveling Control: When one of the doors is opened, the solenoid valve is energized by action of plunger type switch at door. Full reservoir pressure passes through solenoid valve and enters each leveling valve above fast leveling piston which moves down to open the metered orifice valve. This open valve permits air pressure from pressure regulator valve or from T-check valve to pass through leveling valve more rapidly. When leveling valve arm is moved up by suspension upper arm or axle, the movement of air pressure from pressure regulator valve is the same as for slow-leveling control system except that the pressure travels around metered orifice valve instead of through the orifice. Downward movement of leveling valve arm also provides same pressure flow as in slow-leveling control system, except that metered orifice valve is open and permits air to exhaust more rapidly from T-check valve.

FORD & MERCURY LEVELING VALVE

REMOVAL & INSTALLATION: *See individual car model air suspension data.*

DISASSEMBLY: Position leveling valve assembly in a soft jawed vise, then remove both the low and high pressure fittings from valve. Remove valve assembly from vise and remove air intake and check valve, spring, and intake and exhaust valve in that order from low pressure side. Remove exhaust end cap from bottom of valve. Remove fitting from underneath metered orifice valve and remove spring and valve. Remove bolt and washer holding operating arm on valve, then drive out pin holding operating arm cam roller on valve body, and remove cam assembly. Remove intake and exhaust plunger and spring from valve. A nylon roller connecting the operating arm cam will be removed with plunger. Remove air spring supply line fitting from valve.

CLEANING & INSPECTION: Clean all metal parts in solvent and dry with compressed air. Inspect threads and valve seats for damage, and correct as required. Inspect valve body for cracks or casting flaws that might cause leakage. If valve body or valves are damaged, it will be necessary to replace complete valve assembly. Inspect all "O" rings and seals for damage, and replace as necessary. Inspect nylon cam roller for evidence of wear.

REASSEMBLY: Position nylon cam roller on operating arm cam, then install intake and exhaust plunger spring. Insert intake and exhaust plunger in its bore and slide the leveling valve arm cam into place so nylon roller fits into slot in intake and exhaust plunger. Move arm cam in and out to align the pin hole in valve body with locating slot in cam, and install pin. Position felt breather over end of intake and exhaust plunger assembly and snap plastic cover in place. Position arm on cam and install bolt and external toothed washer. Install intake and exhaust valve and check valve spring. Position check valve over spring and install low pressure line fitting. Insert fast-leveling operating piston in high pressure line orifice and install high pressure line fitting. Install metered orifice valve with the wobble wire and spring. Install plug and seal in metered orifice valve bore and air spring supply fitting.

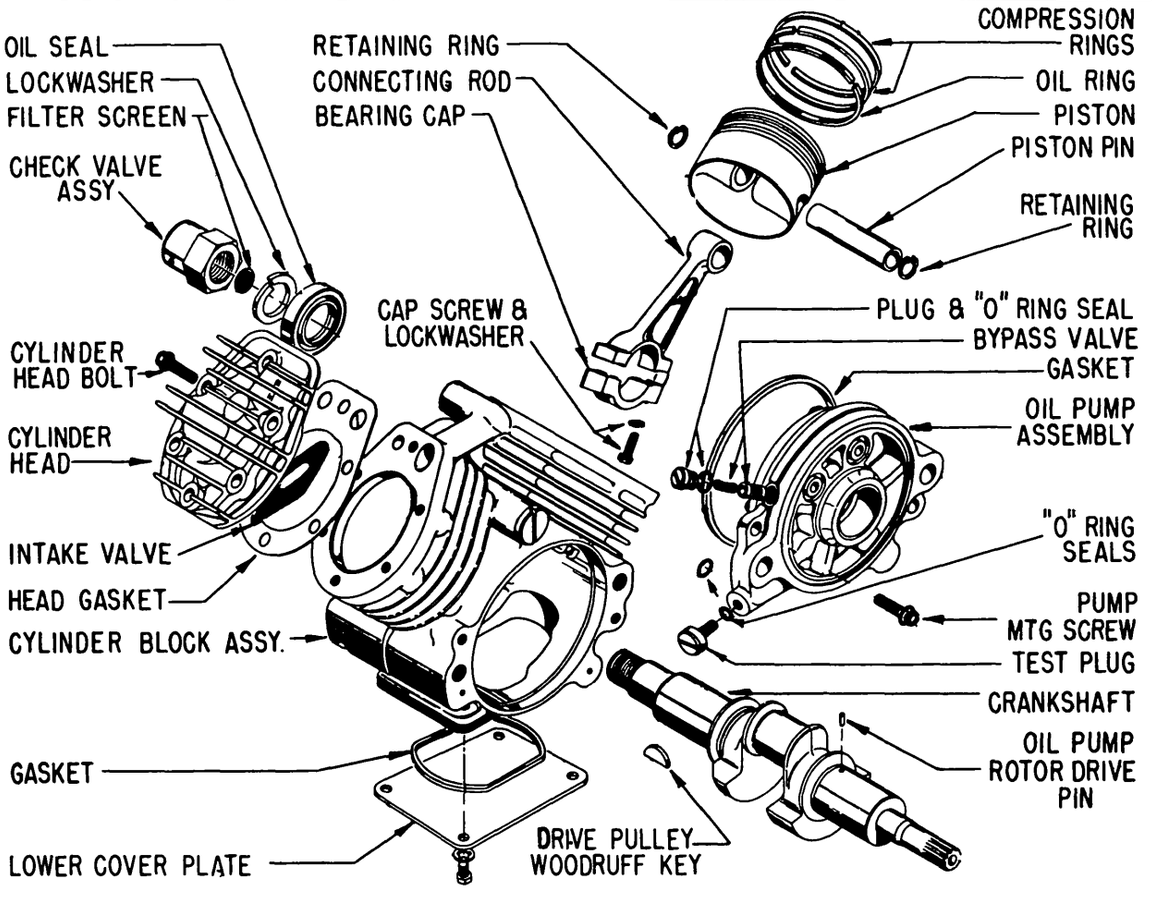
AIR SUSPENSION COMPRESSORS

Car Model	Air Compressor Type
Buick (1958)	G.M. 2 Cyl.
Buick (1959)	G.M. 1 Cyl.
Cadillac (1958-60)	G.M. 2 Cyl.
Chevrolet (1958-59)	G.M. 1 Cyl.
Ford (1958)	Ford, Merc., Rambler
Mercury (1958)	Ford, Merc , Rambler
Oldsmobile (1958-59)	G M. 2 Cyl.
Pontiac (1958-Early 1959)	G.M. 2 Cyl.
Pontiac (Late 1959)	G M. 1 Cyl.
Rambler (1958-60)	Ford, Merc , Rambler

DESCRIPTION: Different type air suspension air compressors used as follows:

G.M. Two Cylinder: "V" type reciprocating type bolted directly to power steering pump and reservoir assembly (Exc. Pontiac with manual steering) On Pontiac models with manual steering, a separate oil reservoir is bolted to compressor in place of power steering pump assembly Compressor is lubricated by a two-stage vane type pump located at drive end of compressor Oil from power steering reservoir (separate reservoir on Pontiac models with Manual steering), flows by gravity into crankcase of compressor where it is maintained at a constant level by one stage of compressor oil pump which returns excess oil to reservoir The second stage of compressor oil pump furnishes pressure lubrication to front and rear crankshaft bushing and connecting rods Cylinder walls and pins are spray lubricated by connecting rods

G.M. One Cylinder: Single stage, single cylinder reciprocating type driven by a belt from engine fan hub assembly Compressor is lubricated by oil from engine pressure oiling system which is introduced through a connection on compressor bearing housing Drilled passages in compressor crankshaft provide lubrication to connecting rod and crankshaft bearings and to cylinder walls Oil is returned to engine crankcase by a line from compressor pump



Ford, Mercury & Rambler: Single cylinder reciprocating type driven by belt from engine water pump pulley (Ford & Mercury); from power steering pump (Rambler Series 20 & 80), from double fan hub (Rambler Series 10). Oil for compressor lubrication is piped from engine lubricating system. A return line allows oil to return to engine crankcase.

REMOVAL & INSTALLATION: *See individual car model air suspension data.*

COMPRESSOR OVERHAUL

G.M. TWO CYLINDER

DISASSEMBLY: Remove grease and dirt from exterior of compressor with a wire brush and air hose. If compressor has an integral reservoir, remove cap and invert reservoir to drain oil. If unit is compressor and steering pump assembly, remove two bolts and carefully withdraw compressor from steering pump so as not to damage pump seals with splines of crankshaft. Remove sump cover plate and gasket. Support unit on its base and remove cylinder heads and gaskets. Clean cylinder heads and mating surfaces on cylinder, then cover underside of head to keep passages clean. Invert unit and remove connecting rod caps, then push pistons, with connecting rods attached out top of cylinder. Remove two bolts attaching bearing plate and oil pump to cylinder block, then carefully slide bearing plate and pump assembly off crankshaft so as to prevent damage to bearing. Remove gasket and "0" rings from plate and pump assembly. Withdraw crankshaft straight out of cylinder housing to prevent damage to bearing. Place a large steel washer (approximately 1½" I.D.) over face of seal opening to protect cylinder housing, then insert tip of screwdriver well into seal flange and pry seal out of bore. Use caution while removing seal to prevent damage to bearing. Remove retaining rings from each end of piston pin and remove pin and connecting rod, then remove three rings from piston. If necessary to disassemble oil pump, see "Oil Pump" below.

G. M. 2 CYLINDER AIR SUSPENSION COMPRESSOR

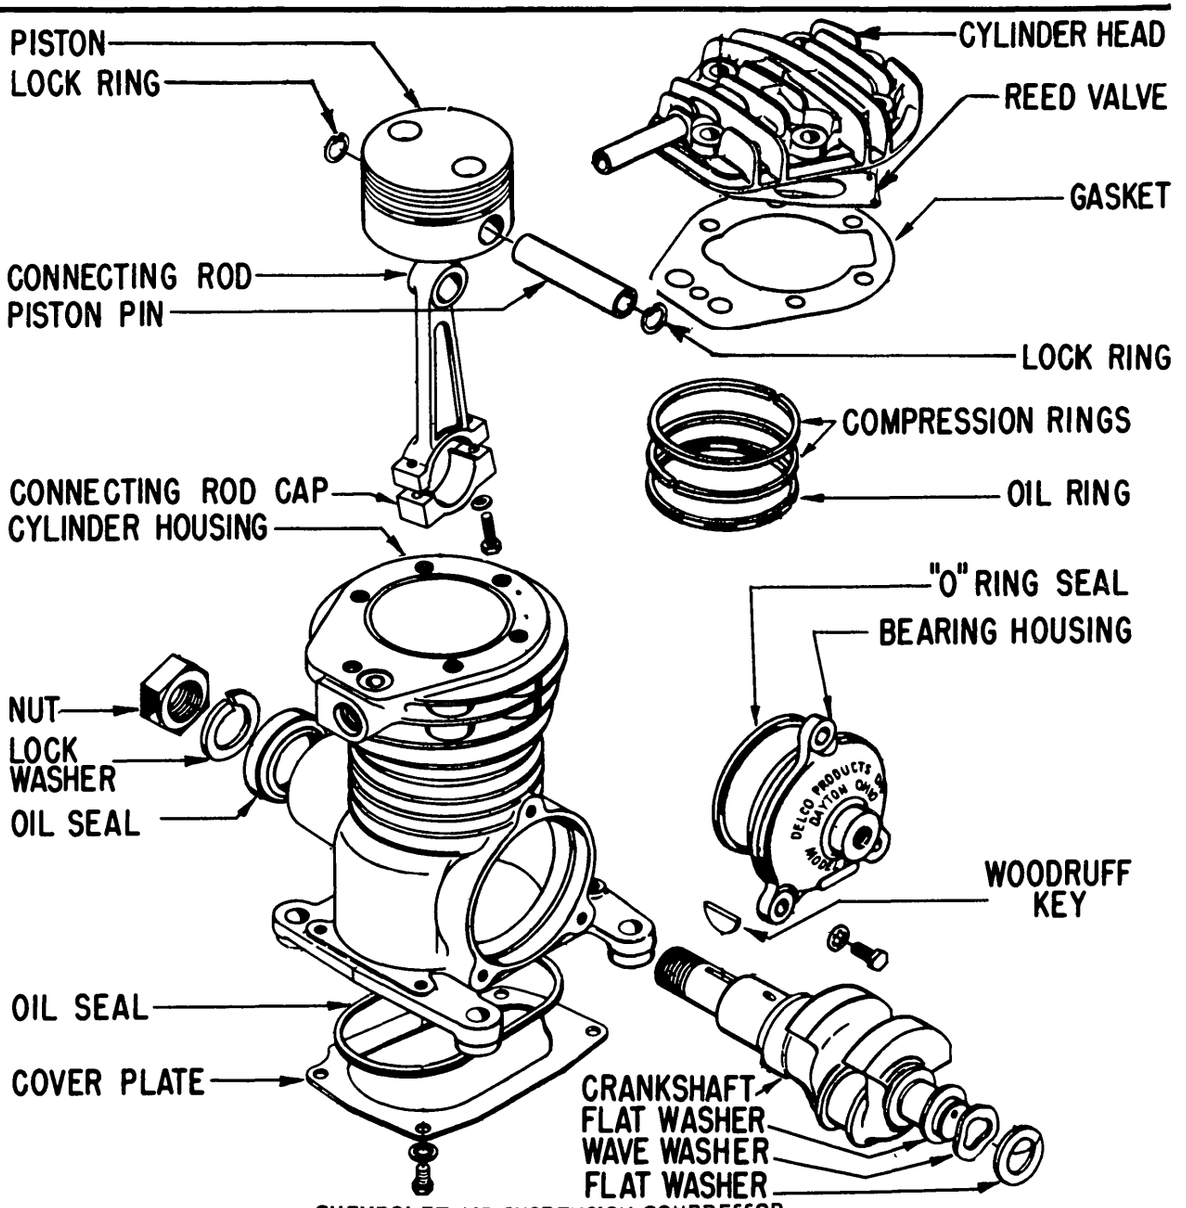
INSPECTION: Wash all parts in solvent and blow dry with air. Check oil passages to insure that openings are free of foreign material. Inspect crankshaft bearings.

REASSEMBLY: Install a new seal in bore using Tool J-7079, so it is flush with top of bore. Lubricate front bearing and seal with power steering oil, then install crankshaft and push it through seal and bearing with a slow, steady pressure. Be sure oil passage in shaft is open. Install new "0" rings in oil pump and bearing plate assembly at oil passage holes, then place a new square cut sealing ring against shoulder in compressor housing. Rotate crankshaft until oil pump drive pin points toward one of the retaining bolt holes in compressor housing, then rotate pump rotor so that slot points toward corresponding hole in bearing plate. Lubricate crankshaft journal and bearing and ease pump and plate assembly over shaft *(CAUTION - Do not force)*. Rotate bearing plate back and forth slightly until drive pin can be felt in rotor slot, then press assembly forward. Install retaining bolts and tighten to 40-50 inch lbs. Inspect piston, pins and rods for excessive wear and replace complete assembly if any part is defective. Position rod into piston and push pin through rod and piston. Replace snap rings at each end of pin and be sure rings seat properly in groove of piston. Before replacing rings, press rings down into bore with piston and check end gaps which should be .002-.007" (two upper rings), .005-.013" (bottom ring). Replace rings on piston with raised dot on each ring in

CONTINUED ON NEXT PAGE

AIR SUSPENSION COMPRESSORS (C nt.)

an up position. Stagger ring openings 120° apart (*CAUTION* - Be sure correct rings are installed in proper grooves of piston). Insert piston and rod assembly through ring compressor, Tool J-7081, until piston skirt extends below bottom of ring compressor. Install assembly into bore with long ear of connecting rod toward top of block, then press piston and rod assembly into bore until rod contacts crankshaft journal. Install rod cap and tighten bolts to 25-30 inch lbs. Install remaining rod and piston assembly in the same manner. Clean oil sump return line filter screen and install it carefully. Place a new square cut rubber sealing ring in channel around sump opening, then replace sump cover and tighten screws to 40-50 inch lbs. Install head gasket using a few drops of oil to hold gasket in position (do not use sealing compound). Make sure intake valve (reed valve) is properly located over dowel pins on head, then replace head and tighten bolts alternately from side-to-side to 80-90 inch lbs. Install remaining cylinder head in same manner.



OIL PUMP: Disassembly - (*NOTE* - Whenever oil pump pressure or flow is not satisfactory; pump must be disassembled). Remove bearing plate and pump assembly from compressor, then bend tabs of pump shield and remove retaining screws. Remove shield and cover, then remove pump vanes and springs. Remove two retaining screws from pump stator, and remove pump rotor and stator. Remove by-pass valve plug, spring, and plunger. Remove test plug.

R assembly & Adjustment: Wash all metal parts in solvent, blow out oil passages, then blow parts dry with air. Replace test plug with a new "0" ring. Replace by-pass valve plunger, spring, and plug, using a new "0" ring. Position pump stator on bearing plate with the six mounting holes aligned and install two stator retaining screws finger tight in threaded holes nearest external mounting holes. Place stator aligning tool, J-7153 in stator cavity making sure that tool is clean and free of oil. (*NOTE* - If crankshaft from compressor is used for alignment, then bearing journals must be within limits of .999-1.000" in two places 90° apart. If not within these limits, a new crankshaft or a plug which meets these limits must be used). Work aligning tool and bearing plate very carefully onto crankshaft to prevent damage to bearing journal. (*CAUTION - Do not use force).* With stator in position where aligning tool and bearing plate rotate freely on crankshaft, tighten two retaining screws. Recheck stator alignment by removing bearing plate from crankshaft, revolving aligning tool 90°, and again placing on crankshaft. Aligning tool should rotate freely on crankshaft and in pump rotor. If tool does not rotate freely, loosen stator retaining screws and repeat alignment procedure. Remove stator aligning tool and install new or acceptable rotor. Install new pump vanes and springs in vane slots. Lubricate pump rotor and vanes with power steering oil. Place pump cover plate and shield in position so holes align and tighten retaining screws to 25-30 inch lbs. Bend tabs of pump shield up in lock position.

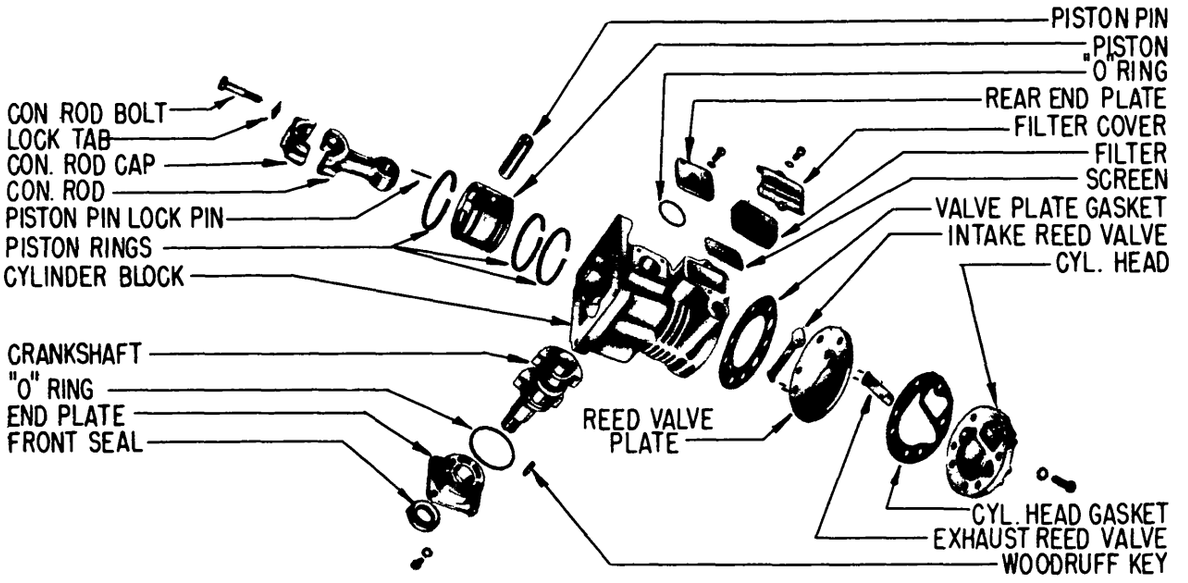
G.M. ONE CYLINDER

DISASSEMBLY: Remove grease and dirt from exterior of compressor with a wire brush and air hose. Invert compressor and remove screws retaining sump cover plate. Remove plate and square cut rubber seal. Place unit on its base and remove cylinder head, flapper valve, and gasket. (*NOTE* - After prolonged service, cylinder head may be hard to remove. If necessary, leave compressor mounted on engine, then back off cylinder head screws 2 or 3 turns and operate engine until cylinder head is loosened). Scrape off gasket material from cylinder head and block, then invert unit and work through sump opening. Remove connecting rod cap and push piston and rod assembly out through top of cylinder. Use Truarc pliers and remove retaining rings from each end of piston pin. Remove piston pin and connecting rod, then remove three piston rings. Remove bearing housing and "0" seal ring. Remove crankshaft from block, pulling straight out to prevent damage to bearing, then remove washers from end of crankshaft or from end of bearing housing. Place a large steel washer (approximately 1½" I.D.) over face of seal opening to

CONTINUED ON NEXT PAGE

CHEVROLET AIR SUSPENSION COMPRESSOR

AIR SUSPENSION COMPRESSORS (Cont.)



protect bore, then insert tip of screwdriver well into rubber seal to insure contact with metal flange and pry upwards (*CAUTION* - Be careful not to damage bearing while removing oil seal).

CLEANING & INSPECTION: Wash all metal compressor parts in cleaning solvent and blow dry with air. Check all openings and passages to make certain they are free of foreign matter and are open. Inspect bore of shaft opening for pitting or scoring. Any such damage should be dressed with fine lapping compound before inserting in new seal. Inspect all parts for wear, pitting, or damage and replace necessary parts. *NOTE* - Piston, pin, and connecting rod are serviced only as an assembly.

REASSEMBLY: Insert a new seal with "Bore-Tite" coating in compressor using Tool J-7080. (*NOTE* - Compressor bodies will have step in which seal must be seated against. Tolerance stack-ups could have seal above, below, or seated flush with compressor lug face when seated against cap). Push crankshaft through bearing and oil seal with a steady pressure to eliminate possible damage to bearing and new seal. Insert a new "O" ring seal in bearing housing opening and slide bearing housing in position. Align mounting holes, insert retaining screws and lockwashers and tighten to 40-50 inch lbs. Install new piston rings on piston in proper location with pip marks up. Position connecting rod in piston and press pin into position and secure piston pin by installing retaining rings at each end of pin. Before installing piston and rod assembly in cylinder, use a hand hone and roughen cylinder walls to remove glaze. Stagger piston ring gaps so they are 120° apart, then insert piston and rod assembly through Tool J-7081 until a portion of piston extends below bottom of ring compressor. Lubricate cylinder walls with light engine oil, then insert piston and connecting rod assembly into cylinder bore making sure that long ear of connecting rod is on down position toward oil outlet opening in cylinder housing. Rotate crankshaft until rod journal is in upper dead center position, then press connecting rod and piston assembly in until rod is in contact with crankshaft journal, then install connecting rod cap and tighten bolts to 25-30 inch lbs. (*NOTE* - Connecting rod and connecting rod cap should be matched by notched flange). Place a new square cut rubber seal in channel around sump opening, then install sump and tighten screws to 40-50 inch lbs. Install new head gasket (do not use gasket compound), then install cylinder head making sure that intake valve is in position on locating pins. Tighten cylinder head bolts to 80-90 inch lbs. Alternate in a triangular sequence to prevent cylinder head distortion.

FORD, MERCURY, RAMBLER

DISASSEMBLY: Clean exterior of compressor with cleaning solvent and a wire brush. Remove crankshaft pulley by removing "nylock" bolt and flat washer. Gently tap pulley from shaft, then remove key from keyway. Remove cylinder head bolts, then remove cylinder head and valve plate. Scrape all gasket material from cylinder head, valve plate, and cylinder block after removing the reed type valves. Be careful not to damage surfaces or reed valve dowel pins and valve seats. Release connecting rod lock tabs and remove bolts. Remove connecting rod and piston assembly by pushing it through top of cylinder bore. Remove crankshaft front end plate capscrews, then remove crankshaft and front end plate by pushing crankshaft through front of crankcase. Remove air filter retaining screws, lockwashers, and cover plate, then remove filter. Remove piston rings from piston, then using needle nose pliers, work out the piston pin retaining (roll) pin from inside diameter of piston pin. Drive out piston pin from piston and connecting rod. If necessary, use a blunt tool.

FORD, MERCURY, RAMBLER AIR SUSPENSION COMPRESSOR

CLEANING & INSPECTION: Clean cylinder head and valve plate to remove all foreign material from discharge and intake cavities. Scrape all dirt and particles of old gaskets from surfaces, then inspect cylinder head and valve for damage, and replace as required. Clean reed type valves by lapping on a piece of crocus cloth on a flat surface. Replace if worn or damaged to to the extent that they do not contact seat. Clean all passages in crankshaft, connecting rod and end covers. Probe and flush with cleaning solvent. Use cleaning solvent to remove foreign material from cylinder block and cavities. Inspect block for cracks or other damage. Wash the air filter and attaching parts in solvent and dry with compressed air. *NOTE - Do not oil the filter.*

REASSEMBLY: Install crankshaft through front of cylinder block, then check clearance between crankshaft and main bearing using a feeler gauge. Install a new crankshaft seal in front cover recess and a new "O" ring seal in groove. (*NOTE* - Coat new seal lightly with sealer and install in front cover recess by using a flat tool or plate and driving gently inward with a mallet until flush or fully seated). Carefully position crankshaft front end plate assembly over crankshaft and into cylinder block recess and tap into place with a mallet. Install bolts and lockwashers and tighten to 6-9 ft. lbs. Check piston bore for out-of-round, and piston fit in bore. Correct as necessary. Position rings in bore and check end gap. Piston bore should not exceed .002" out-of-round, or taper should not exceed .003". Piston ring end gap should be .005-.015". Install connecting rod in piston, then install pin and align piston pin lock pin hole in relation to hole in piston boss. Lubricate pin with engine oil and install lock pin. Using a pin punch, drive pin slightly below surface, and secure by staking hole slightly. Install piston rings on piston (all rings are identical) so dot mark on chamfered side of ring is upward. Stagger end gaps so they are approximately 120° apart. Check ring to groove side clearance which should be .002-.006". Position crankshaft rod journal toward bottom dead center, then install piston and connecting rod assembly in cylinder bore so piston pin lock pin (roll pin) is at the air inlet side of cylinder block. Lubricate bearings, piston and cylinder bore with clean engine oil then install piston fully into position using fingers or ring compressing tool. Install connecting rod cap and tighten bolts to 6-9 ft. lbs. (*NOTE* - Machined ribs on cap and rod should match). Secure connecting rod bolts by bending lock tab against flat of bolt heads. Position valve plate gasket, intake valve, valve plate, discharge valve, cylinder head gasket, and cylinder head on cylinder block. Install cylinder head bolts and tighten to 15-17 ft. lbs. Install air filter in cylinder block recess, then install cover plate and retaining screws and tighten securely. Install crankshaft pulley key in crankshaft keyway and install crankshaft pulley. Install "nylok" bolt and flat washer and tighten to 14-18 ft. lbs. Check compressor for freedom of rotation.

IMPORTANT—Refer to the "Annual Data" for all data on car models later than 1960.

STEERING LINKAGE

►*STEERING LINKAGE (POWER STEERING CARS)*

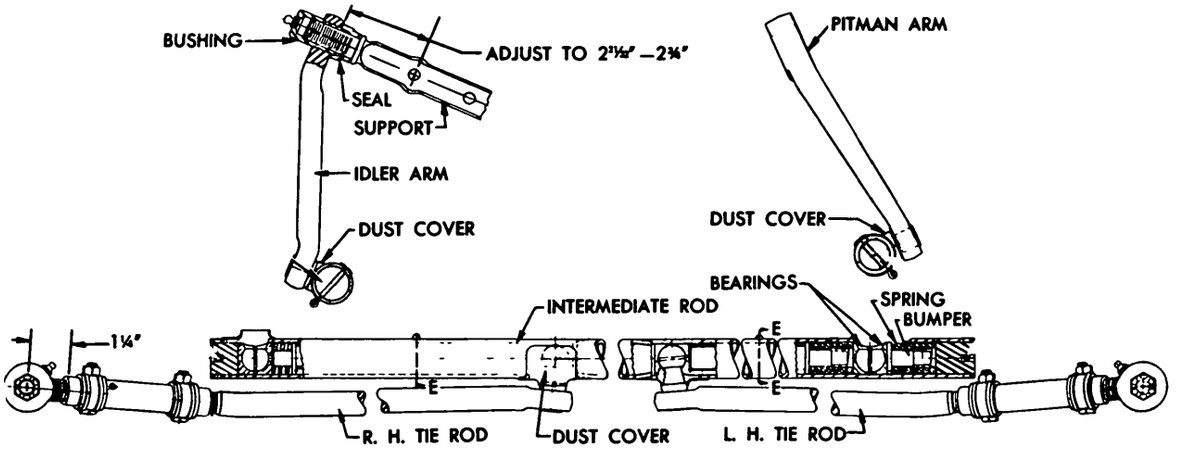
NOTE: Linkage on these cars is essentially the same as for manual steering cars. *See individual Power Steering pages for diff r nc s.*

STEERING LINKAGE & ADJUSTMENT: Special linkage and adjustment on cars and trucks as follows:

1954-60 BUICK

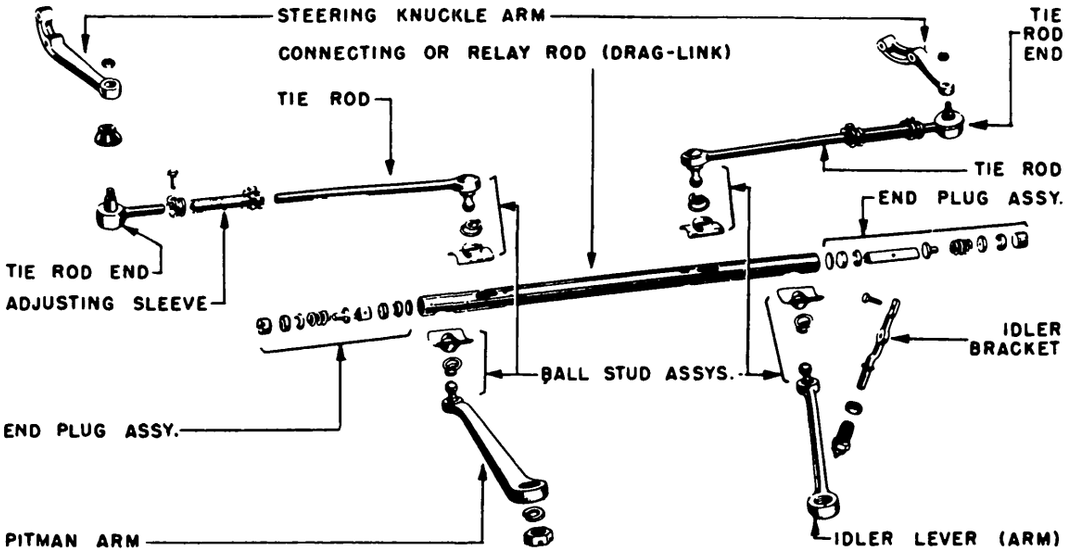
Buick: Linkage—Consists of an intermediate rod between steering gear pitman arm and idler lever on right side of frame, and individual tie rods between intermediate rod and each wheel. Adjustable sleeves provided at end of each tie rod for toe-in adjustment.

Idler Lev r & Supp rt Adjustment—In order that idler lever ball stud is kept level with pitman arm ball stud, thread support into idler arm bushing until distance from center of support lower bolt hole to nearest face of idler lever is 2 21/32" to 2 3/4" (1954-58); 2 15/16" to 3" (1959-60).



Int rm diat Rod End Plug Adjustment - On idler lever end of rod, turn end plug up tight, then back off ¼-½ turn (½ turn preferred) and install cotter pin. On pitman arm end of rod, tighten end plug, then back off 2±1/8 turns (1954-58 Manual Steering); 4±1/8 turns (1959-60 Manual Steering). On Power Steering cars, tighten pitman arm end in same manner as for idler arm end.

1954-60 CADILLAC



Cadillac: Linkag—Consists of a drag link between steering gear pitman arm and idler arm mounted on right frame side rail, and individual tie rods between drag link and each wheel. Adjustable sleeves provided at outside ends of tie rods for toe-in adjustment.

Drag Link Adjustm nt - Place a straight bar across two adjustable jacks directly below drag link, then adjust jacks so that distance from top of bar to flat spot on frame (1954-56); ½" outboard of frame side rail (1957-60) is equal on both sides. *NOTE - Adjusting jacks to even number of inches will aid in measurements.* Measure distance from bottom of drag link to top of bar on both sides. Difference in measurement bxtween first measurement (top of bar to point on frame) and second measurement (bottom of drag link to top of bar) should be 4 7/8" (1954-56); 4½" (1957-60) and equal at both ends of drag link within 1/8". *CAUTION - Drag link must be parall l to frame, within 1/8".* If idler end of drag link not within limits, remove idler arm support mounting screws on frame side bar and screw idler arm in or out of bushing until correct height obtained. *CAUTION - Wh n turning idler arm into bushing to raise drag link, be sure idler arm is at least ½ turn from base or exc ssive play will exist.* If proper height cannot be obtained with this adjustment, replace idler arm. If pitman arm end of drag link is not within limits, pitman arm must be removed and bent as required.

Drag Link Plug Adjustments - Install end plug in pitman arm end of drag link and adjust by turning down tight and backing plug off ¼ to ½ turn. Install cotter pin. Install right end plug and make the same adjustment. Install cotter pin.

BUICK STEERING LINKAGE

CADILLAC, CHEVROLET, OLDSMOBILE, PONTIAC STEERING LINKAGE (TYPICAL)

Idler Arm Support Adjustment—Turn idler arm support with seal into idler arm bushing until it bottoms, and then back off 1/2 to 1 1/2 turns.

1954 CHEVROLET PASS. CARS

Chevrolet Passenger Cars: Linkage—Consists of steering idler and third arm mounted on frame cross member and linked to each front wheel by separate tie rods (adjustable rod on left side, non-adjustable rod on right side). Idler arm is linked to steering gear pitman arm by steering connecting rod (adjustable for length to enable maintaining high point of steering gear adjustment with front wheels straight-ahead).

St ring C nn cting Rod Adjustm nt—If wheels not in straight-ahead position with steering gear on high point, set front wheels in straight-ahead position (can be checked by measuring distance between lubrication fitting on lower control arm shaft and the wheel fellow on each side). Remove ornamental cap or horn button and check position of mark on end of worm shaft designating gear high point (mark should be at top of shaft). If gear has been moved off high point when setting wheels in straight-ahead position, loosen steering connecting rod adjuster clamps and adjust as necessary to bring gear back on high point.

Idler & Third Arm Pivot Pin Bushings Replacement—Drive out old bushings using K-318 steering knuckle bushing driver. Press new bushings in bracket using Tool K-318. Ream bushings to .922-.923" using J-3189 bushing reamer.

CONTINUED ON NEXT PAGE

STEERING LINKAGE

(C ntinu d)

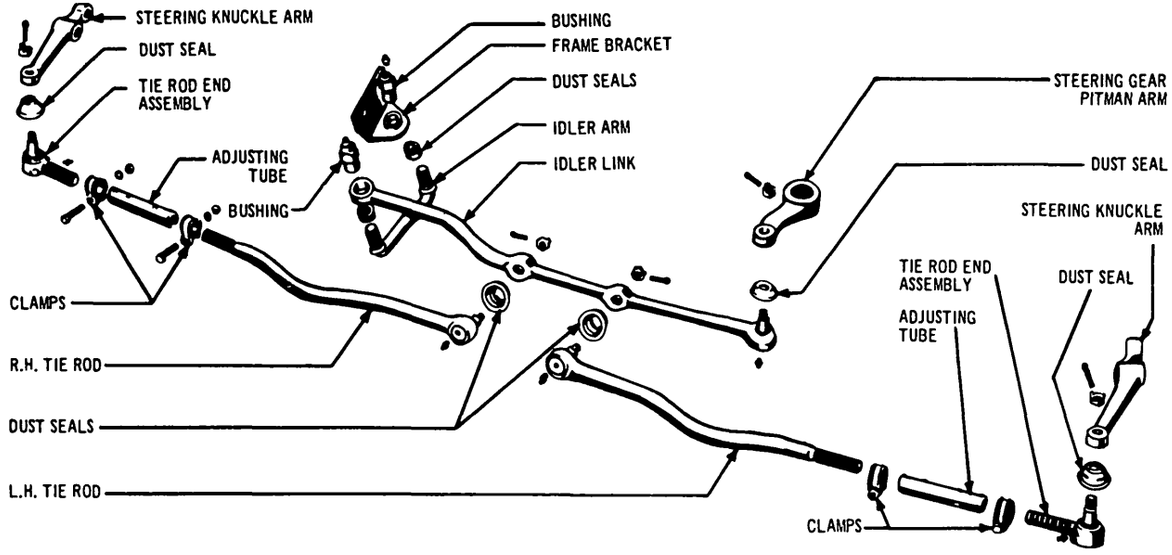
Idler & Third Arm Clearance Adjustment—If clearance between idler and third arm and bracket exceeds .006", when measured with a feeler gauge, install shim, Part No. 3687657, between bracket and lower face of idler and third arm assembly. If clearance between front suspension cross member and bracket at upper mounting hole exceeds .008", when measured with feeler gauge, add shims as necessary to bring space within allowable limits (.010" shims available).

1955-57 CHEVROLET PASS. CARS

Ch vrolet Passenger Cars: Linkage—Consists of steering connecting rod between pitman arm and idler arm, bracketed on right frame side rail, and individual adjustable tie rods between steering connecting rod and each front wheel. Tie rods have adjusting sleeves at outer ends for making toe-in adjustment.

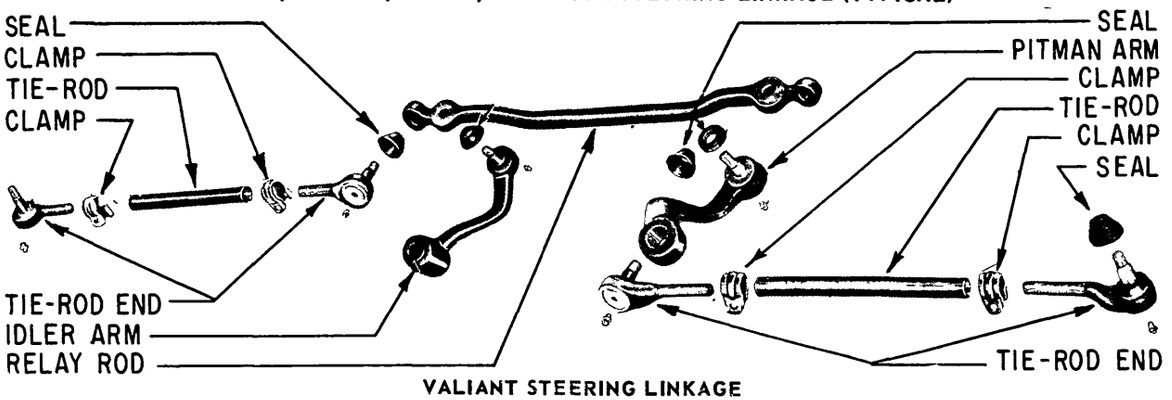
Steering Connecting Rod Adjustment - If wheels not in straight-ahead position with steering gear on high point, set front wheels in straight-ahead position (can be checked by measuring distance between lubrication fitting on lower control arm shaft and the wheel fellow on each side). Remove ornamental cap or horn button and check position of mark on end of worm shaft designating gear high point (mark should be at top of shaft). If gear has been moved off high point when setting wheels in straight-ahead position, loosen adjusting sleeve clamps on both left and right hand tie rods, then turn each sleeve an equal amount in same direction to bring gear back to high point. *CAUTION* - Turning sleeves an unequal amount or in different directions will disturb toe-in.

Idler Arm Bushing Replacement - Remove relay rod from idler arm bracket. Press out old bushing, press in new bushing. Install idler arm over idler arm bracket and install nut but do not tighten. Install relay rod to idler arm and do not tighten. Place wheels in straight ahead position and steering gear on high point, then tighten idler arm nut and relay rod nut to 70 ft. lbs. Advance nuts to align castellations and insert pins.



1958-60 CHEVROLET PASS. CARS (EXC. CORVAIR)

Ch vrolet Passenger Cars: Linkage—Consists of steering connecting rod between pitman arm and idler arm bracketed on right frame side rail, and individual adjustable tie rods between steering connecting rod and each front wheel. Tie rods have adjusting sleeves at outer ends for making toe-in adjustment.



Idler Arm Inspection - Remove idler arm from bracket and remove relay rod from idler arm. Remove idler arm stud seals and all grease, then inspect idler arm for damage or wear. Place idler arm in vise, turn nut on stud until nut bottoms on threads. Torque to turn stud should be not less than 1 ft. lb. not more than 10 ft. lbs. Replace idler arm when turning torque not within specifications.

1954-59 CHEVROLET TRUCKS

Ch vrol t Trucks: Linkage—Consists of three-piece tie rod (rod and two tie rod end assemblies) between front wheels. Tie rod end assemblies have right and left hand threads to facilitate toe-in adjustment. A connecting rod, between steering third arm (on left wheel) and pitman arm, has permanently installed studs in ends. Ends of studs are threaded and are attached to steering third arm and pitman arm with a nut and cotter pin.

CHRYSLER, DESOTO, DODGE, PLYMOUTH STEERING LINKAGE (TYPICAL)

VALIANT STEERING LINKAGE

1960 CHEVROLET TRUCKS

Chevrolet Trucks: Linkage - Consists of two tie rod assemblies connected between pitman arm and wheel on left hand side and between idler arm and wheel on right hand side. A relay rod is connected between pitman arm and idler arm.

Idler Arm Inspection: Remove idler arm from bracket and remove relay rod from idler arm. Remove idler arm stud seals and all accumulated grease, then inspect arm for wear or damage. Place idler arm in a vise and turn nut on stud until nut bottoms on threads, then use a torque wrench to turn stud. Note the reading which should not be less than 1 ft. lb. or more than 10 ft. lbs. Replace idler arm if not within limits.

Idler Arm Bushing Replacem nt - *NOTE - On S ri s 10 through 40, idler arm bushing is n t replac abl .* On Series 50 & 60, remove idler arm, then press bushing out with Tool J-1614. *NOTE - Wh n pr ssing bushing from housing, pressing tool must thr ad down through one bushing and onto top of low r bushing. Aft r pressing this bushing out, turn support housing ov r and press second bushing out. Always pr ss from inn r rim of bushing toward outside of housing.* Press new bushing into place with Tool J-7079-2 and Tool J-8522. Bushings will be properly located in bore when pressed in until tool contacts housing.

1954 CHRYSLER & DESOTO

Chrysler & DeSoto: Linkage—Consists of steering gear intermediate arm mounted on frame cross member which transmits motion from steering gear, through drag link, to each front wheel, through independent tie rods. Both tie rods are adjustable.

CONTINUED ON NEXT PAGE

STEERING LINKAGE (C ntinu d)

Drag Link Installati n—Whenever drag link removed, care must be taken to insure proper reinstallation in order to provide clearance on extreme turns. It will be noted that one end of drag link is offset slightly, while other end is straight. Offset end should be connected to steering gear arm. On most cars, the drag link is marked "Rear" on the ball retainer expansion plug at rear end to insure proper installation.

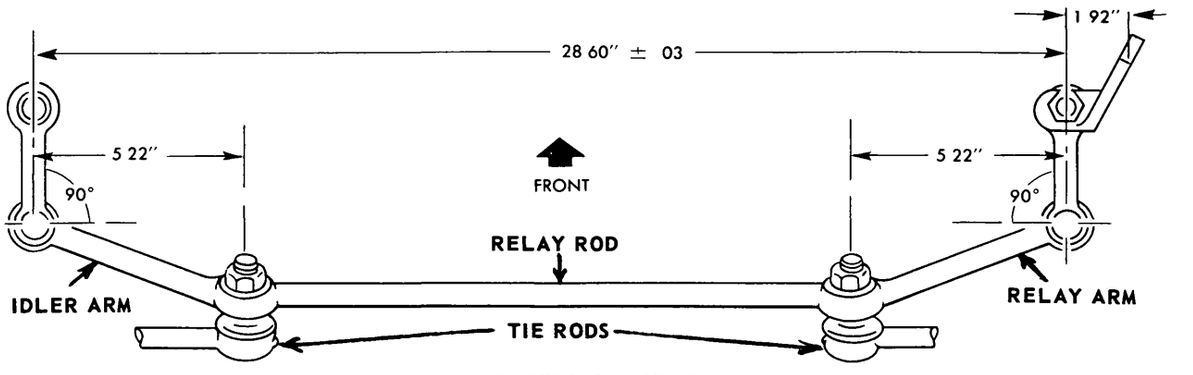
Int rmediate Arm B aring Adjustment—Insert sufficient number of shims between upper bearing race and arm spacer so that when assembly is clamped in vise, arm can be rotated with a pull of approximately 1 lb. at end of arm (drag link end).

1954-55 DODGE 6 & PLYMOUTH

D dg 6 & Plym uth 6: Linkage—Consists of long and short tie rods (both adjustable) attached directly to steering gear arm

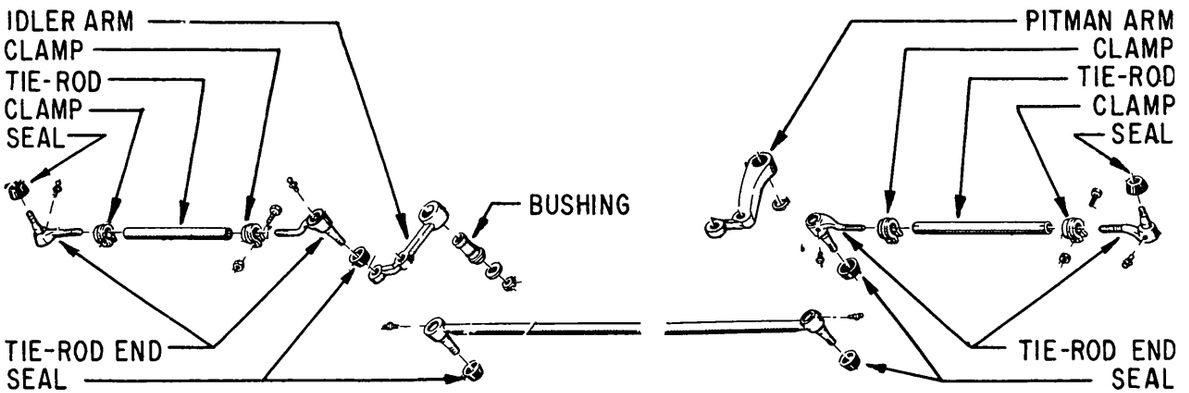
1955 CHRYSLER, DESOTO & PLYMOUTH 8 1954-55 DODGE V8

Chrysl r, D S to, D dge V8, Plymouth V8: Linkage—Consists of idler arm bracketed to right frame side side member and connected to right end of drag link. Pitman arm is connected to left end of drag link. Individual tie rods, connected to drag link near its center, have sleeve adjustment for toe-in at ends.



Idl r Arm Cl aranc Adjustment—Screw idler arm support bracket into bushing until it bottoms. Then back off approximately one full turn of idler arm or, until a clearance of 1 7/16" plus or minus 1/16" has been obtained between shoulder of bracket and flat surface of arm.

Idl r Arm Bushing R placement—If idler arm bushing play exceeds 1/8" when idler arm is moved up or down or, if noise has developed in steering linkage a new idler arm bushing, support bracket or both should be installed as follows: Remove cotter pin, nut and spacer that holds drag link end ball stud to idler arm. Insert pry bar between idler arm and drag link. Jar drag link ball stud loose by driving on end of link. Separate link and arm, then remove seal. Remove two bolts and lockwashers that attach idler arm support bracket to frame side rail. Remove support bracket, idler arm and bushing as a unit. Unscrew idler arm support bracket from idler arm bushing, then remove seal. Clamp end of idler arm bushing in a vise and remove locknut. Now, unscrew idler arm from bushing. (NOTE—Before removing idler arm from bushing, mark flat of arm to indicate up or down side. Arm has tapered hole for ball stud and can only be installed in one position). To install, reverse removal procedure, noting "Idler Arm Clearance Adjustment" above. If straight fitting (lubrication) found on end of bushing, replace with a 60° or 90° fitting for ease in lubrication.



1956-60 CHRYSLER, DESOTO, DODGE, PLYMOUTH & VALIANT

Chrysl r, D S t , D dg , Plym uth (All): Linkage - Consists of idler arm bracketed to right frame side member and connected to right end of drag link. Pitman arm is connected to left end of drag link. Individual tie rods, connected to drag link near its center, have sleeve adjustment for toe-in at outside ends.

Idler Arm Bushing Replacement - Idler arm with bushing is serviced only as an assembly. When bushing worn replace assembly. Opening in Idler Arm Bracket between Idler Arm Bushing positions or contact points should be 2¼" (Exc. Valiant). Bend bracket to correct.

CORVAIR STEERING LINKAGE

COMET & FALCON STEERING LINKAGE

1960 CORVAIR

Corvair: Linkage - Consists of a relay rod connected between pitman arm and steering idler arm located on right hand side of frame. Tie-rods are connected between relay rod and each front wheel.

Relay Rod and Idler Arm Bushing Replacement - *NOTE - Early models have a replaceable bushing at each end of relay rod, and at each end of idler arm. On later models a replaceable bushing is provided only at pitman arm end of relay rod.* With relay rod or idler arm removed from car, drive bolt out of bushing, then use a suitable size socket to press bushing sleeve and rubber out of relay rod or idler arm. Press a new bushing into place with Tool J-8357. *CAUTION - When installing relay rod in car, idler arm and pitman arm must be in proper alignment (see illustration). Be sure to hold hex head of bushing bolts so bushing will not be twisted.*

1960 COMET & FALCON

Comet & Falcon: Linkage - Tie-rods are connected between pitman arm and wheel at left side of car and between steering idler arm and wheel on right side of car. A relay rod connects pitman arm and steering idler arm. Tie-rod ends are replaceable while relay rod ends are not. When worn or damaged, relay rod must be replaced.

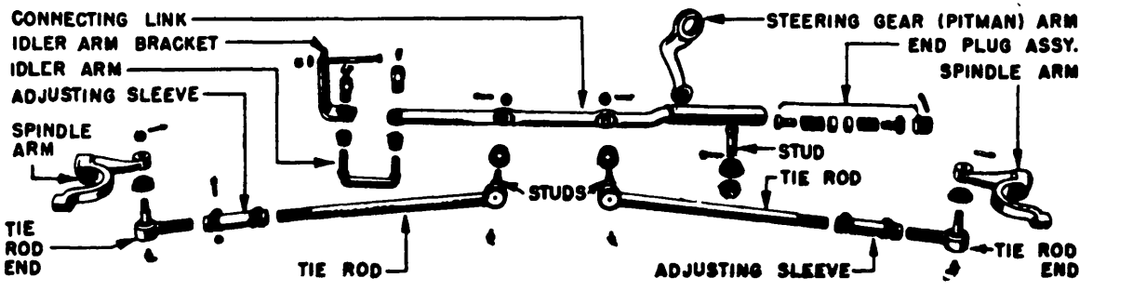
1954 FORD PASS. CARS

Ford Passenger Cars: Linkage—Consists of steering arm-to-idler arm rod which transmits motion from steering gear through steering arm, attached to left end of steering arm-to-idler arm rod, to front wheels through spindle connecting rods (tie rods). Spindle connecting rods have adjustable sleeves on outside ends for toe-in adjustment. Idler arm attached to right frame side rail and to right end of steering arm-to-idler arm rod.

Idler Arm & Bracket Adjustments—Steering idler designed to operate with 1/8" vertical free play. To reduce, proceed as follows (same procedure used when replacing idler arm or bushings): Remove bracket from frame side rail. Thread bracket and bushing off idler arm, then remove idler arm from steering arm-to-idler arm rod. Remove bushings from idler arm bracket and steering arm-to-idler arm rod, remove

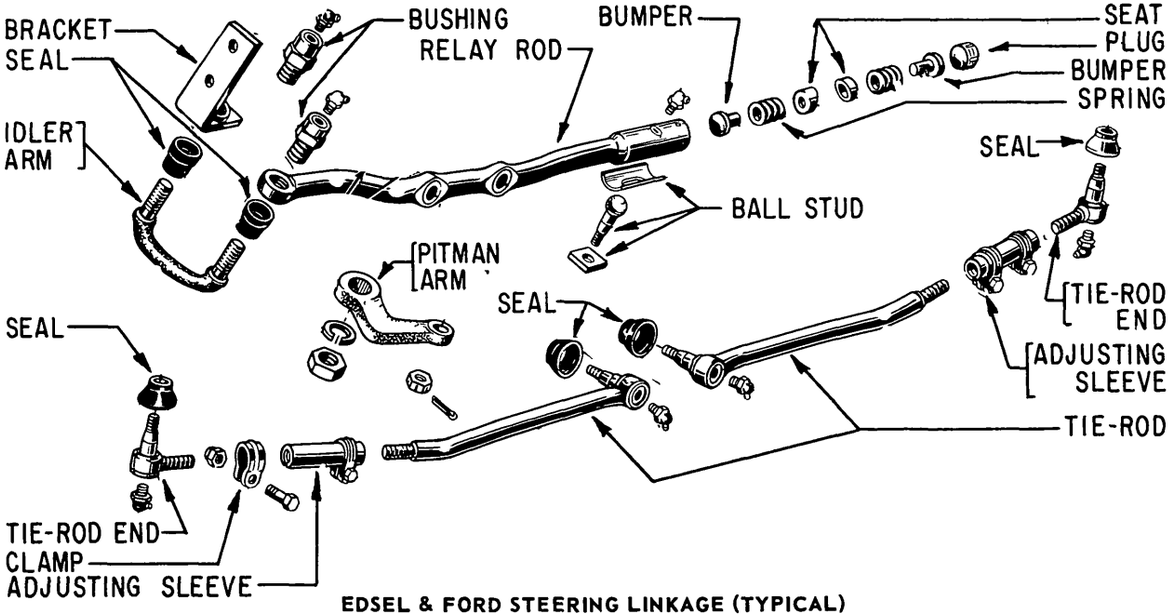
CONTINUED ON NEXT PAGE

STEERING LINKAGE (C ntinu d)



lubrication fittings from bushings. Check face of side rail for squareness by placing car on level floor, then measure distance from each side rail to floor. If distances unequal, jack up lower side rail until even with other rail. Place spirit level against inside surface of right hand side rail, adjacent to idler arm position, then establish true perpendicular. Measure distance between edge of level and side rail. Distance represents amount of spacing washers that must be installed between bracket and side rail to correctly position idler arm bracket. Check idler arm bracket for 92° included angle (between inside faces of bracket) and correct if necessary. Replace bushings in bracket and in steering arm-to-idler arm rod. Tighten bushings to 85-100 ft. lbs. torque. Reinstall grease fittings. Place new seals on idler arm. Thread idler arm into idler arm rod bushing until shoulder on arm is 11/16" plus or minus 3/64" from top face of rod when arm is in straight-ahead position. Thread bracket and bushing assembly onto idler arm until shoulder on arm is 19/32" plus or minus 3/64" below bottom side of bracket when bracket is parallel to frame side rail. Mount bracket on frame side rail, installing necessary number of washers between bracket and frame. Tighten attaching bolts to 30-35 ft. lbs. torque.

Ball Socket Adjustment—Whenever steering arm ball stud found to have play in socket, remove cotter pin from end of rod, tighten threaded plug in end of socket until all ball stud end play removed, then back off plug approximately 1 1/2 turns, install new cotter pin. Test adjustment by turning steering arm-to-idler arm rod by hand. Rod must move freely, but there should be no end play at ball stud.



1956-60 FORD PASS. CARS

F rd Passenger Cars: Linkage - Consists of steering arm-to-idler arm rod which transmits motion from steering gear through pitman arm, attached to left end of steering arm-to-idler arm rod, to front wheels through spindle connecting rods (tie rods). Spindle connecting rods have adjustable sleeves on outside ends for toe-in adjustment. Idler arm attached to right frame side rail and to right end of steering arm-to-idler arm rod.

Idler Arm & Bushing Replacement - Remove bracket from frame side member, then remove bracket and rear bushing from the idler arm. Remove idler arm from bushing in steering arm to idler arm rod, then remove seals from both ends of idler arm. Remove bushings from idler arm bracket and steering arm to idler arm rod. Replace bracket if cracked or bent. DO NOT STRAIGHTEN IDLER ARM BRACKET. Install new bushings in steering arm to idler arm rod and idler arm bracket and tighten bushings to 85-100 ft. lbs. then install new seals at both ends of idler arm. On 1956-58 models, thread arm into bushing in idler arm-to-steering arm rod until shoulder on arm is 19/32"±3/64" from top face of rod when arm is in straight ahead position. Thread idler arm bracket and bushing on arm until shoulder on arm is 19/32"±3/64" below bottom side of bracket when bracket is parallel to frame side member.

LINCOLN & MERCURY STEERING LINKAGE (TYPICAL)

EDSEL & FORD STEERING LINKAGE (TYPICAL)

On 1959-60 models, thread arm into bushing in steering arm-to-idler arm rod until arm bottoms, then back off arm about ¾ turn. Thread idler arm bracket and bushing onto arm until bushing bottoms, then back off bushing until bracket mounting surface is parallel with frame side member. On all models, install bracket on frame side member and tighten mounting bolts to 28-43 ft. lbs. (1956-58); 25-30 ft. lbs. (1959-60).

1954-60 FORD TRUCKS

Ford Trucks: Linkage—Consists of a connecting rod between front wheels. Rod has adjustable features at both ends. Spindle arm, attached to connecting rod at its left end, is in turn attached to a one-piece drag link with manual adjustment features at both ends. Rear of drag link is attached to sector shaft arm (pitman arm).

Drag Link Adjustm nt—Remove cotter pins from each end of drag link. Tighten each drag link plug until drag link ball springs are fully compressed. Back off each plug to first cotter pin hole, then install new cotter pins.

1954 HUDSON

Hudson & Hudson Jet Linkage: Consists of center steering arm on frame crossmember linked to each front wheel by adjustable tie rods and to pitman arm by a short drag link.

Center Steering Arm Adjustm nts—Using Tool J-2953 adjust arm for centered position as follows: Remove center steering arm nut and front bolt from arm support bracket, install gauge clamp over steering arm, install gauge. Insert bolt at front of gauge in hole in bracket from which bolt removed. Attach screw in center steering arm shaft, adjust gauge rods to contact both sides of front wheel evenly. Repeat procedure for opposite wheel, adjust tie rods equally until reading is same on both sides.

Center Steering Arm Pivot Shaft R plac m nt Adjustm nt—Press new shaft in place maintaining the 2.052-2.055" dimension from top of upper spacer and top of lower spacer before drilling and reaming hole for No. 5 taper pin.

CONTINUED ON NEXT PAGE

STEERING LINKAGE (Continued)

1954-60 LINCOLN & MERCURY 1958-60 EDSEL

Lincoln, Mercury & Edsel Linkage - Consists of steering connecting link between steering gear arm (Pitman Arm) and idler arm, mounted on right frame side rail, and adjustable tie rods between connecting link and each front wheel. Adjustable sleeves provided at outside ends of tie rods for toe-in adjustment.

Connecting Link Plug Adjustment - Screw end plug in left end of connecting link until it bottoms, then back off plug the number of turns indicated in table below. Align cotter pin holes and install cotter pin.

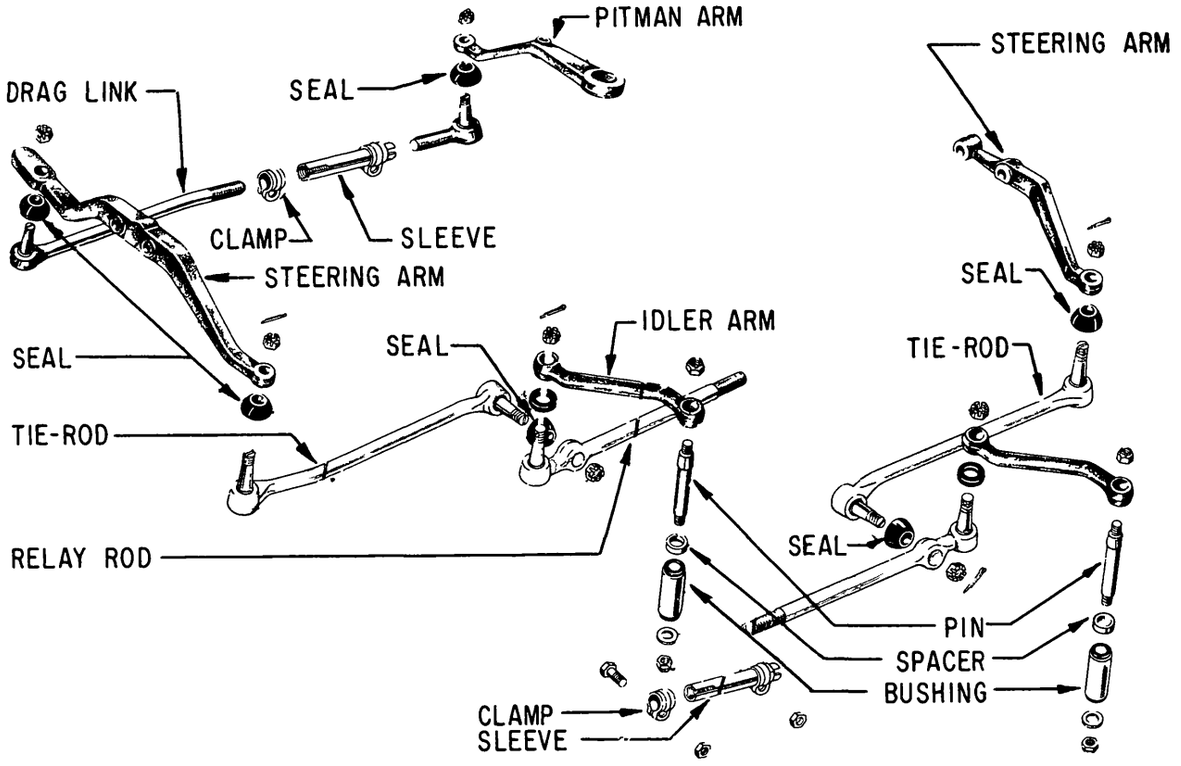
Car Model	℄ Plug Adjustment
1954-55 Mercury	1½ turns
1954-55 Lincoln	2-2½ turns
1956-57 Lincoln & Mercury	1-1½ turns
1958 Lincoln (Torsion Bar Strg.)	1¾-2½ turns
1958 Lincoln (In-Line Steering)	¾-1½ turns
1958-60 Edsel	1½ turns
1959-60 Lincoln	¾-1½ turns
1958-60 Mercury	¼-¾ turns

℄ - Plus or minus 1/8 turn to align cotter pin holes.

1955-57 HUDSON, 1954-57 NASH & RAMBLER

Nash (Exc. Metropolitan), Rambler: Consists of steering linkage cross tube between steering gear pitman arm and idler arm, bracketed on right frame side rail. Individual adjustable tie rods are attached to ends of cross tube. Adjusting tubes at outer ends of tie rods provide for toe-in adjustment.

1958-60 RAMBLER



Rambler: Linkage - Except on Series 20, relay rod is connected between pitman arm and steering idler arm with tie-rod on left side connected between pitman arm and steering arm. On right side, tie-rod is connected between idler arm and steering arm. On Series 20, relay rod is connected between idler arm at each frame side rail and steering arm at right and left sides of car. A tie-rod at forward side of suspension crossmember connects pitman arm to steering arm. Ball and socket joints are adjustable on Series 01, 10, & 80 and are not adjustable on Series 20.

Ball & Sock t Joint Adjustment - Tighten adjusting plug until solid contact is made, then back off plug to first cotter pin hole, not to exceed ¼ turn or less than 1/8 turn. *NOTE - On Series 10, pitman arm side, tighten end plug solid, then back off 1½-2 turns.*

1954-60 OLDSMOBILE

Oldsmobile: Linkage—Consists of steering relay rod between pitman arm and idler arm, bracketed to right frame side rail. Individual, adjustable tie rods are attached to center portion of steering relay rod and are provided with adjustable sleeves for toe-in adjustment.

Relay Rod Plug Adjustment—Draw nut tight, then back off 1/4-3/4 turn, install cotter pin.

RAMBLER STEERING LINKAGE (1958-60 SERIES 20 SHOWN)

Idler Lever & Support Adjustment—Whenever idler arm is disassembled from idler arm support, reassemble so that there is a dimension of 23/32" between upper face of idler arm and shoulder on support.

1954-56 PACKARD

►*NOTE See "Studebaker-Packard" below for 1957-58 Models.*

Packard: Linkage—Consists of steering connecting rod between pitman arm and idler lever, bracketed to right frame side member, and individual tie rods (steering cross tubes) between steering connecting rod and each wheel. Adjusting sleeves at outer ends of cross tubes provide means for toe-in adjustment.

Connecting Rod End Plug Adjustment—Draw plugs up tight, then back up 1/4-1/2 turn to align slot with cotter pin hole.

1954-60 PONTIAC

Pontiac: Linkage—Consists of steering connecting rod between pitman arm and idler arm, bracketed on right frame side rail, and individual, adjustable tie rods between steering connecting rod and each front wheel. Tie rods have adjusting sleeves at outer ends for making toe-in adjustment.

Idler Lever & Support Adjustment - With lever and support off car, thread idle support into bushing until distance between upper face of lever and shoulder on support is approximately 11/16".

Steering Connecting Rod Plug Adjustment - Screw end plugs in until tight, then back off to nearest cotter pin hole alignment and insert new cotter pins.

1954-60 STUDEBAKER & 1957-58 PACKARD

Studebaker: Linkage—Consists of two adjustable tie rods attached to bell crank mounted at center of frame cross member. Bell crank is attached to steering gear pitman arm by a reach rod (drag link).

Bell Crank Bearing Adjustment—Insert shims between lower thrust washer and shaft until there is no end play. Shaft should, however, turn freely in bearings. Lock nut securely with cotter pin.

1954-60 WILLYS UTILITY

Willys Utility: Linkage—Bell crank on frame cross member, linked to each front wheel by adjustable tie rods and to steering gear pitman arm by a steering connecting rod (drag link).

ℂ - Saginaw (Not-in-Line) Power Steering used on Early 1959 Silver Hawk Models before Serial No 59V-34592 See *"Saginaw (Not-in-Line) Power Steering"*

►CHANGES, CAUTIONS, CORRECTIONS

►***1954 FORD 6 CYL. PUMP LEAKAGE CORRECTION:*** To minimize leakage at unused return port on pump, a plug (B4A-3569-A) and gasket (B4A-3592-A) are available for service and should be used to replace cup type plug used on earlier models

►***1955 FORD PRESSURE CHECK GAUGE ADAPTER KIT CHANGE:*** Due to pump design change in May, 1955 it is necessary to use new adapters for pump fittings Fittings can be made up using ⅝" inverted male connector (87974-S), 2¼" inverted female connectors (87200-S), 3⅝" inverted flare nuts (87953-S), a ⅝" short nut (87424-S), a ⅝" male connector (87234-S) and two pieces of soft copper tube 2½" long, ⅜" O D

►***1955 MERCURY PUMP PRODUCTION CHANGE:*** New pump differs from earlier type in that return port has been moved from pump body to a position on side of reservoir near bottom. Adapter, No 3500-C must be used with Pressure Check Gauge No 3500 when checking pressures See Ford Pressure Check Gauge Adapter Kit Change (above).

►*1956 FORD POWER STEERING SQUEAL CORRECTION & PUMP PULLEY PRODUCTION CHANGE.* A new pump pulley, Part No B6A-3356-A and a new solid type pump belt is used in production and may be used for service replacement to correct pump belt squeal. The early type belt, with serrations, can be used with either early or late type pulleys

►*1956 FORD STEERING ARM & LINKAGE INTERFERENCE WITH POWER STEERING CONTROL VALVE CORRECTION:* Check the steering arm-to-idler arm rod and replace it if it is bent If interference exists after new arm is installed, replace the spindle connecting rod assembly (Part No AD-3280-B) If the two above corrections do not eliminate the interference, it may be necessary to replace the lubricant fitting or grind off the boss of the oil pressure line on power steering cylinder *CAUTION* - A wall thickness of 3/32" must remain after grinding is completed.

►*1956 MERCURY POWER STEERING CONTROL VALVE INTERFERENCE CORRECTION & DRAG LINK ADJUSTING CAUTION:* When installing the left hand drag link adjusting sleeve, the clamps should be installed with bolts in a vertical position and forward of the steering link to prevent interference with the control valve.

►*1957 MERCURY CONTROL VALVE CENTERING SPRING CHANGE (To provide heavier steering feel in center position):* A new heavier spring, Part No. MG–33704–B, replaces the earlier spring, Part No. MG–33704–A in production. On cars with 368" engine the later type spring must be used for service replacement. On cars with 312" engine, either spring may be used. For identification, the early spring is dyed a maroon color, and the later spring is dyed green.

►*1957 MERCURY POWER STEERING NOISE CORRECTION:* A new power steering pressure line hose, Part No. MG-33589-A, having a relocated step-down orifice and revised dimensions for steel tubing at each end of hose to improve clearances in valve and pump areas

►*1958 EDSEL CONTROL VALVE INSTALLATION NOTE·* Distance between center of ball stud in sector shaft arm and center of stud at inner end of left-hand spindle connecting rod should be 10 7/8" (Ranger, Pacer, and Station Wagons), 11 1/4" (Corsair and Citation models).

►*1958 EDSEL HYDRAULIC PUMP BELT CAUTION (Early Cars)·* DO NOT use ½" x 40 ½" long belt (found on some early cars). Use pump belt B8A-33558-D (3/8" x 39" long) which can be properly adjusted (14-16 ft lbs. slip) without placing pump at undesirable position.

►*1958 FORD RESERVOIR COVER LEAK CORRECTION:* Remove cover and filter spring, then push new seal ring 372144-S down around cover stud until seal ring is on top of metal filter retaining washer Install spring, cover, and flat washer and secure with wing nut. **DO NOT** rework flat washer under wing nut.

►*1958 FORD HYDRAULIC PUMP NOISE CORRECTION:* Before replacing improved type hydraulic pump (with yellow stripe), check the following items and correct as necessary: Fluid level in reservoir, Belt tension, Air in system, Hoses properly routed to eliminate interference with frame or sheet metal, Leaks causing low oil level in reservoir.

►*1958 THUNDERBIRD BELT INTERFERENCE CORRECTION (Early Cars with Air Conditioning)·* When belt interferes with radiator lower hose it should be replaced with Belt No B8A-33558-D identified by numerals EDD-33558-A on outside of belt. Late cars have new belt installed.

►*1958 FORD STEERING WHEEL SHUDDER CORRECTION·* When shudder is present while car is standing still and the wheels are turned rapidly, it is caused by incorrect pump belt adjustment. Adjust belt to 25 ft. lbs. slip torque.

►*1958 MERCURY VALVE CENTERIMG SPRING NOTE:* Lighter valve centering spring No. MG-33704-A released to reduce turning effort Install lighter spring **only** after eliminating all excessive binding and checking the following points Misalignment of steering gear at frame or instrument panel, Steering gear worm and sector preload adjustment, pitman arm to frame interference *(see "Pitman Arm to Frame Interference Note" below)*, and incorrect hydraulic pressures.

►*1958 MERCURY PITMAN ARM TO SIDE RAIL INTERFERENCE CORRECTION:* Increase clearance between frame and pitman arm by installing shims between gear box and frame or by grinding off excessive forging flash (if advisable), from pitman arm.

►*1958 MERCURY CONTROL VALVE REMOVAL & INSTALLATION CAUTION:* Use wrench only (not pipe wrench), on cast iron valve housing to remove valve. This will prevent distortion of sleeve which would result in a binding and restricting of the movement of ball stud socket in sleeve.

►*1958 MERCURY CRACKING NOISE ON TURNING CORRECTION:* Cracking noise caused by serrated washer on inner idler arm bushing turning. To correct, install serrated washer with serrations **d wnward** and tighten nut to 50-65 ft. lbs.

►*1959 EDSEL POWER STEERING PUMP RESERVOIR LEAK CORRECTION* Oil leakage past the power steering pump reservoir stud and cover can be corrected by installing a new type seal, Part No 372144-S DO NOT try to correct leakage by venting the reservoir, reservoir cover, or by reworking cover retaining flat washer

►*1959 POWER STEERING PUMP HOSE INTERFERENCE (6 CYL MODELS).* To prevent possible hose failure caused by hose rubbing on left hand horn, drill a 3/8" hole, 2 3/8" above original horn mounting hole in front fender apron and radiator support and install horn in the new location

►*1959 EDSEL POWER STEERING HYDRAULIC CONTROL VALVE PRODUCTION CHANGE (For Improved Steering & Recovery)* A revised control valve assembly, Part No B9AA-33577-B, identified by a daub of yellow paint is being used on later cars and may be used for service replacement on early 1959 models *DO NOT USE on 1958 cars* The new valve incorporates a valve spool with the center land reduced in width to a nominal 020" New centering spring and centering spring washers are also used

►*1959 EDSEL & 312" ENGINE MEPCUPY POOR RECOVERY FROM LEFT HAND TUPN CORRECTION* To correct this condition, remove centering spring spacer from control valve assembly and measure length of spacer with a micrometer If it is not at specified length of 879- 880", rework spacer to proper length by filing with a fine file *CAUTION - Keep ends of spacer square and remove burrs after filing* Install plastic spring seat, reworked spacer, centering spring, outer plastic spring seat, small washer, and adjusting valve spool nut Tighten spool nut until it bottoms, then back it off ¼ turn Install centering spring cap and retaining screws

►*1959 EDSEL & FORD POWER STEERING PUMP REPLACEMENT CAUTION* Pumps used on 1959 models must have "850 Max " etched in relief valve cap 1959 pumps have a maximum pressure of 850 lbs maximum which must be used with the larger diameter power cylinder *DO NOT USE 1958 Pumps for replacement* These pumps have a maximum pressure of 1050 lbs and are identified by either "1050 Max " etched in relief valve cap or by a stripe of yellow paint

►*1959 EATON ROLLER TYPE POWER STEERING PUMP NOISE CORRECTION (ALL MODELS)* To eliminate the noise in power steering pumps (after a cold start), install revised pump carrier, with rollers and cam which is available in a kit, Part No B9MY-3A711-A The later type parts are used in all pumps built after March 11, 1959 The revised carrier can be identified by a circled "A" and the words "This Side Up" that are marked on side of carrier *S e "Eaton Roller Type' Power Steering Pumps in 1958 Annual Data or later Manual edition for installation proc dures*

CONTINUED ON NEXT PAGE

BENDIX LINKAGE TYPE (C ntinued)

►*1959 MERCURY 383' & 430' ENGINE POWER STEERING PUMP PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE* A new power steering pump assembly, Part No B9ME-3A576-B having a two bolt (in place of a four bolt mounting used previously) is being used in production and may be used for service replacement on earlier models with crankshaft mounted pump When installing this unit on earlier cars two nylock setscrews, Part No UP-372816-S must be used to plug existing unused mounting holes in front cover Two insulators, Part No B9ME-3A577 A installed in unused bolt holes must be inserted from rear of housing Two insulators, Part No B9ME 3A584-A installed in bolt holes are inserted from the front of housing The existing reservoir (pump intake) hose must be replaced by a longer one Part No B9ME-579-A *NOTE* When using an old pump with a new type engine front cover, Part No B9ME-6059-C two new front insulators, Part No B9ME-3A584-A must be used for attaching old pump to new front cover New insulators are inserted from front side into the two bolt holes The existing one-piece insulators should be used in unused holes with larger diameter of insulators between pump and front cover

►*1959 MERCURY STEERING WHEEL SHAKE & STEERING SHAFT RATTLE CORRECTION* Check thrust loading spring located between flange of steering gear assembly and steering shaft flange and insulator for proper thrust load as follows Loosen setscrew on flange and insulator assembly then move insulator down against force of thrust loading spring by prying on upper flange *NOTE This will preload steering shaft bearing, eliminating looseness* While prying downward tighten setscrew *CAUTION - Flange and insulator assembly should be moved just enough so that deformation of steering shaft flange insulator is held to a minimum*

►*1959 MERCURY 383' & 430' ENG POWER STEERING CONTROL VALVE SEAL REPLACEMENT NOTE* New type seals Part No B9MY-3A650-A (complete kit) should be used whenever control valve is disassembled *See Overhaul below for installation procedures*

►*1959 MERCURY POWER STEERING PITMAN ARM REMOVAL TOOL 3290-B REWORK NOTE* To use this tool approximately ½" has to be removed from end of threaded screw The overall length of screw should be 2 5/8" *CAUTION - Fork type or other similar tools should not b used as they will damage power steering valve*

►*1960 MERCURY (383" & 430" ENG.) CRANKSHAFT MOUNTED POWER STEERING PUMP PRODUCTION CHANGE:* An Eaton "roller" type pump is being used on later production cars replacing the former "vane" type pump The new pump is identified by the letter "M" following date code which is stamped on mounting face of pump

►*1960 MERCURY ERRATIC POWER STEERING ASSIST CORRECTION:* This condition may be caused by moisture in control valve assembly. To correct, apply a "4X" silicone grease or its equivalent in the centering spring area on all cap and spacer mating surfaces and in all bolt holes Threads of cap retaining bolts should also be coated before assembly.

DESCRIPTION: "Linkage Type" with control valve assembly and power cylinder built into steering linkage or attached to it The units used on 1959-60 Mercury models with 383" & 430" engines have a "Reaction Limiting Valve Assembly" incorporated into main control valve This valve assembly limits amount of effort required to turn steering wheel when parking or when making sharp turns at low speeds

ADJUSTMENT: Pump Drive Belt - Procedures are different as follows

1954-57 Ford (All Models) - Place a heavy duty "C " clamp on pump bracket so pressure can be exerted on the movable adjusting bracket above the adjusting lock bolt. Loosen adjusting bolt enough to permit moving pump when "C" clamp is tightened, then tighten "C" clamp until pulley slips against belt friction when a torque of 14—16 ft. lbs. is applied to pump pulley bolt, using a torque wrench. *(NOTE* - Pull on wrench as if tightening bolt). Tighten belt adjusting bolt to 30—35 ft. lbs. and mounting bolt to 20—25 ft. lbs.

1958-60 Ford (292" Eng.) - Place a heavy duty "C" clamp on adjusting bracket, then loosen pump adjusting bracket, pump support bolts, and pump-to-exhaust manifold so "C" clamp can be tightened Tighten "C" clamp to obtain 25 ft lbs slip torque on belt (torque wrench applied to pump pulley nut) Tighten all bolts to 20-25 ft lbs

1958-60 Ford (6 Cyl.) - Loosen top pivot bolt on pump adjusting bracket and adjust bolt to obtain ½" belt deflection

1958-60 Ford (Spec. V8 & Thunderbird) - Loosen bracket adjusting bolt and pivot bolt, then move pump until pulley slips against belt friction at 25 ft lbs (21-23 ft lbs on 1958 Thunderbird) Tighten all bolts to 20-25 ft lbs

1954-58 Mercury (All Models) - Adjust pump belt tension to obtain ¼" belt deflection at center with 5-7 lbs pull Tighten nuts to 20-25 ft lbs

1959-60 Mercury 312" Eng.) - *NOTE - Other models have a crankshaft mounted pump.* With 7-9 lb force applied upward on belt midway between pulleys, belt deflection should be ¼" To adjust, loosen pivot and adjusting bolts on pump mounting bracket and move bracket in its adjusting slot Tighten pivot bolt to 20-25 ft lbs

1958 Edsel (All Models) - Use torque wrench and socket on pump pulley bolt Torque required to slip pulley against belt friction should be 14-16 ft lbs

1959-60 Edsel (All Models) - Use a torque wrench and measure torque required on pulley bolt to cause belt to slip Torque should be 23-25 ft lbs To adjust, loosen belt pivot and adjusting bolts on pump mounting bracket, then raise pump body

1958-60 Studebaker - Belt deflection should be 1/4-3/8" (1958-59), 3/16-1/4" (1960) with a 4 lb pull midway between pulleys To adjust, loosen bracket mounting screws and shift pump body to secure proper belt tension

LUBRICATION: Check fluid level every 1000 miles (Ford & T-Bird), 2000 miles (Edsel & Mercury), 5000 miles (Checker Superba & Studebaker) Start engine and turn steering wheel right and left a few times, then shut off engine Add Automatic Transmission Fluid to bring level up to following specifications

►*1960 MERCURY POWER STEERING CONTROL VALVE LUBRICATION CAUTION:* When lubricating power steering control valve, the two clamp screws retaining protective boot on sleeve should be removed to allow escape of chassis lubricant Boot will be ruptured if screws not removed

1959-60 Checker Superba: Bring level to within 1" of top of reservoir
1958 Edsel: ½" from top of reservoir
1959-60 Edsel: Bring level up to "Full" mark
1954-57 Ford: Bring level up to "Full" mark
1958-60 Ford & T-Bird: ¼" from top of reservoir
1954-60 Mercury Bring level up to "Full" mark.
1958 Studebaker: Bring level to within 1" of top of reservoir
1959-60 Studebaker: Bring level up to mark indicated on side of reservoir

TESTING: Turning Effort - With front wheel properly aligned and tire pressures correct, place car on dry concrete, set parking brakes, then proceed as follows: With engine running at normal idle speed, turn wheel to right and left several times to bring fluid to normal operating temperature. Hook a spring scale to rim of steering wheel and measure pull required to turn wheel at least one complete turn in both directions. The pull should be about equal in both directions as shown in table below

Model	Lbs. Pull
Edsel (1958-60)	7-12
Ford Pass Cars (1954-58)	7-12
Ford Pass Cars (1959-60)	7
Thunderbird (1955-57)	7-12
Thunderbird (1958)	(Maximum) 7
Thunderbird (1959-60)	Ⓒ
Mercury (1954-58)	7-12
Mercury 312" Eng (1959-60)	7-12
Mercury 383" & 430" Engs (1959-60)	5-7
Studebaker (1958-60)	11

Ⓒ - On 1959-60 Thunderbird, check turning effort at wheel nut with an inch-pound torque wrench Torque required should be 7-11 inch-pounds

Pump Pressure: Install a suitable pressure gauge between pump hose and pump outlet with pressure gauge between pump and shutoff valve of pressure gauge Run engine at idle speed (with shutoff valve open) for two minutes to normalize temperature, then turn wheel all the way to right then to left Note fluid pressure reading on gauge when each wheel is against its stop, see table below for correct pressures *CAUTION - Do not hold wheel against its stop for more than 30 seconds* If pressure is less than minimum, pump is faulty If pressure increases but does not reach maximum, inspect pump, control valve, and power cylinder If pressure is within limits and steering gear does not function properly, trouble is in control valve or power cylinder

CONTINUED ON NEXT PAGE

BENDIX LINKAGE TYPE (C ntinu d)

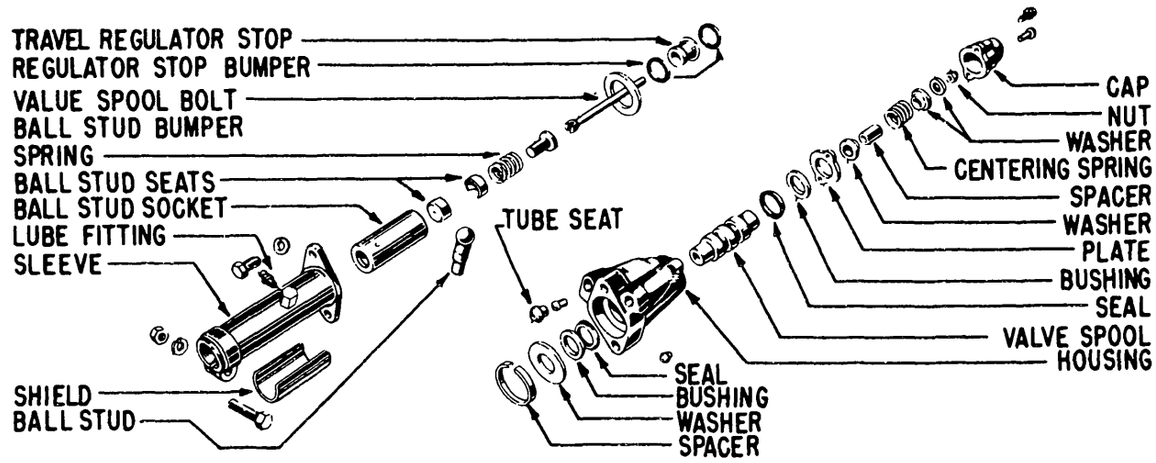
Pr ssur Rang

Model	Pressure (Lbs.)
1954-57 (All Models)	700-900
1958 Edsel	975-1100
1958 Ford (Exc. Thunderbird)	700-900
1958 Thunderbird	900-1050
1958 Ford Truck	900-1050
1958 Mercury	800-1000
Checker Superba (1959-60)	700-900
Edsel (1959)	700-900
Edsel (1960)	700-850
Ford & T-Bird (1959-60)	700-850
Mercury (1959-60)	800-1000
Studebaker (1958-60)	850

TROUBLE SHOOTING: Binding or Poor Recovery - Check pitman arm ball stud in control valve sleeve which may be rubbing against the sleeve slot. If this is the case, the roll pin may be missing. Check idler arm bushings. Check all steering gear adjustments. Check operation of control valve and for interference between sector shaft arm and dust shield. Check control valve travel regulator stop adjustment. Check for damaged control valve sleeve and socket tube.

Hard Steering: Check to see that pump drive belt is properly tightened and that pump pressure is correct. If pump pressure is within specifications, check control valve spool centering spring adjustment. Check control valve spool for free movement and repair as necessary. See *"Binding or Poor Recovery"* above.

Excessive Free Play: Check steering gear worm and roller mesh adjustment. Check for excessive clearance between steering arm ball stud and ball stud seats. If ball stud is loose in seat, adjust control valve travel regulator stop. Check control valve centering spring adjustment.



Noisy Pump: Check pump belt tension. Noise may also result if correct hose is not used *(see "Changes, Cautions, Corrections" above).*

Steering Chatter: A loose pump belt can cause chatter against the wheel stops during an extremely sharp turn. Check belt tension. Check for looseness in idler arm connection, and check idler arm bushing. Check power cylinder piston rod insulators for looseness.

Loss of Power Assist: Check for damage or broken hoses. Check pump pressure (see above). Disconnect power cylinder piston rod from idler arm bracket and operate piston by hand to check for resistance to movement. If piston moves freely with little or no resistance, internal parts of power cylinder are damaged. Replace cylinder. Check adjustment of valve spool centering spring. Check operation of control valve check valve.

OVERHAUL

CONTROL VALVE: Removal (Exc. Studebaker) - Disconnect hoses at control valve (turn wheels to force out fluid). Loosen clamp at right hand end of sleeve, then pull roll pin out of steering arm-to-idler arm rod through slot in sleeve. Remove cotter pin from control valve ball stud nut, then loosen nut and back it off far enough

EDSEL, FORD & MERCURY POWER STEERING CONTROL VALVE ASSEMBLY

to cover threads on end of ball stud. Hold a soft hammer against forward side of sector shaft arm to absorb the shock, then lightly tap ball stud with a hammer to loosen it from arm. *(CAUTION - Do not strike any part of valve body while loosening ball stud).* Remove nut from end of ball stud, then raise control valve high enough to remove ball stud from pitman arm. Turn front wheels fully to left and turn control valve counterclockwise to remove it from steering arm to idler arm rod.

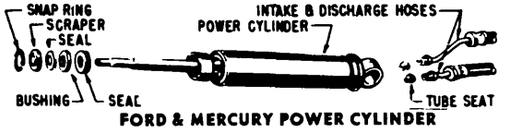
Removal (Studebaker): Disconnect hoses at pump body, reservoir, and power cylinder. Drain fluid from hoses, then remove hose retaining clips. Disconnect reach rod from steering bellcrank, then remove pitman arm from steering gear shaft with Puller J-5664. Remove control valve, reach rod and hoses from car as an assembly. *CAUTION - Before removing valve assembly from reach rod, clean assembly to remove dirt and grease from valve body, then loosen clamp on actuator sleeve and screw valve assembly off reach rod, counting the number of turns required to unscrew valve from reach rod. Record the number of turns for use at installation to maintain proper reach rod length.*

►*1959-60 MERCURY (383" & 430" ENG.) CONTROL VALVE DISASSEMBLY & REASSEMBLY NOTE:* These control valve assemblies have a "Reaction Limiting Valve" which is disassembled and reassembled as follows: After control valve is disassembled (see above), remove aluminum plug and "O" ring assembly (see illustration) from each end of control valve body, then remove springs, washers, and reaction valve. To reassemble, insert washer, spring and longest plug and "O" ring assembly into valve housing from sleeve end. Carefully insert reaction valve into bore of valve housing from spring cap end, then insert washer, spring and short plug into housing.

Disassembly: Remove two centering spring cap bolts and cap from valve housing. *(CAUTION - When holding control valv in a soft jaw d vis for disass mbly, clamp valv only around th sl eve flang).* Remove nut from end of valve bolt, then remove washers, spacer, centering spring, adapter and bushing. Remove two bolts holding valve housing and sleeve together, then separate housing from sleeve. Remove lubrication fitting from sleeve and push valve spool out of centering spring end of housing. Remove seal from spool. Remove spacer, bushing and seal from sleeve end of valve housing. Drive stop pin out of travel regulator stop with a punch and hammer *(NOTE* - Pull head of valve spool bolt tightly against travel regulator stop before driving pin out of stop). Turn travel regulator stop counterclockwise in valve sleeve to remove stop from sleeve. Remove valve spool bolt, spacer, and rubber washer, from travel regulator stop. Remove dust shield from valve sleeve. Slide bumper, spring, and ball seat out of sleeve, then remove ball stud socket.

Inspection: Wash all parts in solvent and wipe with a lint free cloth. Inspect valve seals and bushings for wear, making sure that lips of seals are not nicked or scratched. Check bushings for nicks or scratches. Inspect valve housing for nicks and burrs. Use crocus cloth to remove burrs, being carefull not to round off sharp edges of spool *'NOTE* - If spool or inside of valve housing are badly scored, replace the assembly). Dry spool and housing thoroughly, and insert valve into housing. The spool should fall freely of its own weight in housing. *(NOTE* - Clearance between spool and housing should be .0002-.0009"). Inspect mating surfaces of ball stud socket and valve sleeve for wear or damage. Remove minor burrs and scores with crocus cloth. Check fit of socket in sleeve. Socket should slide freely in sleeve.

►*RELIEF VALVE & HOSE SEAT REPLACEMENT NOTE:* If replacement is necessary, proceed as follows: Tap existing hole in hose seat, using a 3/8" starting tap for large hose seat and a 1/4" starting tap for small seats. *(CAUTION - Remov all metal chips from s at ports after tapping).* Place a nut and large flat washer on a bolt of the same size as tapped hole. *(NOTE* - Washer must be large enough to cover hose seat port). Insert bolt in tapped hole, then use it as a puller to



CONTINUED ON NEXT PAGE

BENDIX LINKAGE TYPE (C ntinued)

remove hose seat. If return line hose was removed, remove relief valve from port with a screwdriver, and install a new relief valve. Place a new hose seat in port, then thread a bolt of the same size as the port into the port. Tighten bolt enough to bottom seat in port.

R ass mbly: Coat all parts with Automatic Transmission Fluid Type "A". Insert one of the ball stud seats (flat end first) into ball stud socket, then insert threaded end of ball stud into socket. Place socket in control valve sleeve so threaded end of ball stud can be pulled out through slot in sleeve. Place other ball stud seat, spring, and bumper in the socket, then install and securely tighten travel regulator stop, Loosen stop just enough to align nearest hole in stop with slot in ball stud socket, then install stop pin in ball stud socket, travel regulator stop, and valve spool bolt. Install dust shield and lubrication fitting on sleeve. *(NOTE* - Make sure lubrication fitting is tight and does not bind on ball stud socket). Insert valve spool in housing so that large end of spool will be at centering spring end of housing and small end of spool will face sleeve end of housing. Rotate spool while inserting it in housing. Move spool toward centering spring end of housing, then place small seal, bushing, and spacer in sleeve end of housing. Press valve spool against inner lip of seal and, at the same time, guide lip of seal over spool with a small screwdriver. *(CAUTION - Do not nick or scratch seal r spool).* Place seal end of bushing on a flat surface so that seal, bushing, and spacer are at bottom end, then push down on valve spool until it stops. Carefully install spool seal and bushing in centering spring end of housing around large end of spool. Press spool against inner lip of seal and guide lip over spool with a small screwdriver. *(CAUTION - Do not nick or scratch s al or spool).* Slide spool back and forth in housing and check for free movement. Place valve sleeve on housing so that ball stud is on same side of housing as ports for the two power cylinder hoses, then install two bolts in sleeve. Tighten to 30-35 ft. lbs. (1954-55 Ford, Mercury & Thunderbird); 17-22 ft. lbs. (1956-60 Ford & Thunderbird, 1956-58 Mercury, 1958 Edsel); 15-20 ft. lbs. (1959-60 Edsel & Mercury); 140-170 inch-pounds (1958-60 Studebaker). Place adapter on centering spring end of housing and install bushing, washers, spacer, and centering spring on valve spool bolt. Compress spring and install nut. Tighten nut securely, then loosen it not more than ¼ turn. Move ball stud back and forth in sleeve slot to check for free movement of spool. *NOTE - This spool sh uld travel approximately .060" in each direction from center.* Install centering spring cap on housing and tighten the two cap bolts to 4-6½ ft. lbs. Install nut on ball stud so that valve can be positioned in a vise with the vise clamping the nut and holding valve securely, then push forward on cap end of valve to check valve spool for free movement. Turn valve around in vise and push forward, checking for free movement.

Installati n: Thread valve on steering arm-to-idler arm rod until about four threads are still visible on the rod. Position ball stud in sector arm, then measure the distance between center of ball stud in pitman arm and

FORD & MERCURY POWER CYLINDER

center of stud at inner end of left hand spindle connecting rod. *(CAUTION - Make sure the measurement is taken parallel to centerline of control valve).* The measurement should be as indicated in table below. If the measurement is not correct, disconnect ball stud from pitman arm and turn valve on steering arm-to-idler arm rod as necessary to obtain the correct measurement. With correct distance obtained and ball stud positioned in pitman arm, align hole in steering arm-to-idler arm rod with slot in end of valve sleeve. Install roll pin in rod hole to lock valve in position on rod. Tighten valve sleeve clamp bolt to 30-35 ft. lbs. Install nut on ball stud and tighten to 56-60 ft. lbs. Install cotter pin. Connect hoses to control valve and tighten all fittings securely. Fill reservoir to "F" mark on dipstick or reservoir with Automatic Transmission Fluid Type "A". Start engine and run at fast idle speed for two minutes, then turn steering wheel to right and left a few times and check for leaks.

Valve Installation Measurement

Model	Dimension
1954-56 Ford & Mercury	9"
1955-56 Thunderbird	9 9/16"±1/32"
1957 Ford (Exc. Thunderbird)	10 7/8"
1957 Thunderbird	9½"
1957-58 Mercury	11¼"
1958 Ford & Thunderbird	10 7/8"
1958 Edsel (Corsair & Citation)	11 1/4"
1958 Edsel (Ranger, Pacer & Sta. Wgn.)	10 7/8"
1959-60 Edsel	11 15/16"
1959 Ford (Exc. Thunderbird)	10 7/8"
1959 Thunderbird	9 1/2"
1960 Ford (Exc. Thunderbird)	12"
1960 Thunderbird	10 3/4"
1959-60 Mercury	9 3/8"
1958-60 Studebaker	See Note Below

►*STUDEBAKER INSTALLATION NOTE:* With control valve reinstalled and control valve assembly screwed into reach rod the same number of turns (recorded at time of removal), set wheels in straight ahead position and center wheel in the high spot. Slip pitman arm on steering gear shaft, aligning marks on arm and shaft, then check distance between center of pitman arm ball and reach rod ball by holding end of reach rod in position at bellcrank. Adjust length of reach rod so that reach rod ball stud will slip into bellcrank without moving front wheels from straight ahead position. *NOTE - It is necessary to remove unit from car to make adjustments.*

POWER CYLINDER: Except for cylinder seal and hose seat replacement, the power cylinder should be replaced as a complete assembly if faulty.

Removal: Disconnect hoses from power cylinder and fasten open ends of hoses in a raised position to prevent fluid draining out. Move front wheels to left and right several times to force all fluid from cylinder. Disconnect piston rod from idler arm bracket, but do not remove at this time. Remove locknut holding cylinder on mounting stud in steering arm-to-idler arm bracket and remove outer washer, bushing, and cylinder from stud. Remove inner bushing and washer from stud and pull inner insulator and washer from piston rod.

Inspection: Clean exterior of cylinder and piston rod. Inspect cylinder and rod for damage or wear and check for leakage. If parts are damaged or piston is leaking internally, replace the entire power assembly. Inspect mounting bushings and insulators for wear or damage and replace as necessary.

►*POWER CYLINDER SEAL REPLACEMENT NOTE:* Install all parts furnished in repair kit as follows: Clamp cylinder in vise and remove snap ring from end of cylinder, being careful not to distort or crack the cylinder. Pull piston rod out as far as it will go, then apply compressed air to other end of cylinder to blow seals out of cylinder. Lubricate new inner seal with Automatic Transmission Fluid Type "A", then place seal, bushing, outer seal, and scraper on piston rod. Push piston rod all the way in, then using a deep socket slightly smaller than cylinder opening, tap parts into cylinder and replace snap ring.

►*HOSE SEAT REPLACEMENT NOTE:* If either seat is damaged, both seats should be replaced as follows: Tap the hole in power cylinder hose seat with a 3/8" starting tap. *(CAUTION - Remove all metal chips from hole after tapping).* Place a nut and large washer (enough to cover seat port) on a 3/8" bolt, then insert bolt in tapped hole and turn it to pull seat out of port. Position a new seat in port, and thread a 5/8"-18 bolt in the port until seat bottoms in port.

Installation: Install inner washer and bushing on mounting stud in steering arm-to-idler arm rod. Install inner insulator and washer on power cylinder piston rod, then install cylinder on mounting stud with piston rod in idler arm bracket. Install outer bushing, washer, and locknut on the mounting stud. If a new nut is installed, tighten it to 60-70 ft. lbs. If a used nut is installed, tighten to 50-60 ft. lbs. Install outer insulator, washer, and nut on piston rod and tighten to specification indicated in table below. Connect hoses to cylinder and tighten fitting securely. Fill reservoir (see "Lubrication" above), then run engine and check for leaks.

POWER STEERING PUMP: *See "Power Steering Hydraulic Pumps" and note the following application for different models.*

1954-57 Ford (All Models) - Eaton "Rotor" type pump.

1958-60 Ford & Thunderbird - Eaton "Roller" type pump.

1954-57 Mercury - Eaton "Rotor" type pump. *NOTE - Used on 312" Eng. (Exc. Turnpike Cruiser & Air Cond. Cars).*

1957 Mercury - Vickers Vane Type pump. *NOTE - Used on Turnpike Cruiser & Air Cond. Cars with 368" Eng.*

1958-Early 1960 Mercury & Edsel - Vane type. Mounted on front of engine and driven directly by crankshaft. *NOTE - Used on some models.*

1958-60 Mercury & Edsel - Eaton "Roller" type pump. *NOTE - Used on some models.*

Late 1960 Mercury - Eaton "Roller" (Crankshaft Mounted) type pump. Mounted on front of engine and driven directly by crankshaft.

1958-60 Stud baker - Eaton "Rotor" or "Roller" type pump; Vickers Vane Type, or Saginaw Vane Type pumps used.

1959-60 Ch ck r Sup rba - Eaton "Roller" type pump.

BENDIX LINKAGE TYPE (NASH, PACKARD)

Nash, Amb. 6 (1954-56)
Packard, Exc. Clipper (1954-56)

DESCRIPTION: This "Linkage Type" Power Steering differs from other types in that the power mechanism is built in the steering linkage (or attached to it) and is used in conjunction with a standard steering gear (gear has special ratio to take advantage of added power). Power steering system consists of the following units:

Hydraulic Pump & Reservoir Assy.—Mounted on the engine and belt-driven from the crankshaft. Consists of an Eaton rotor type pump with a built-in Relief Valve (pre-set to specified limits—See Testing Hydraulic Oil Pressure below) and Flow Control Valve (limits maximum volume, at high engine speed, to steering gear requirements.

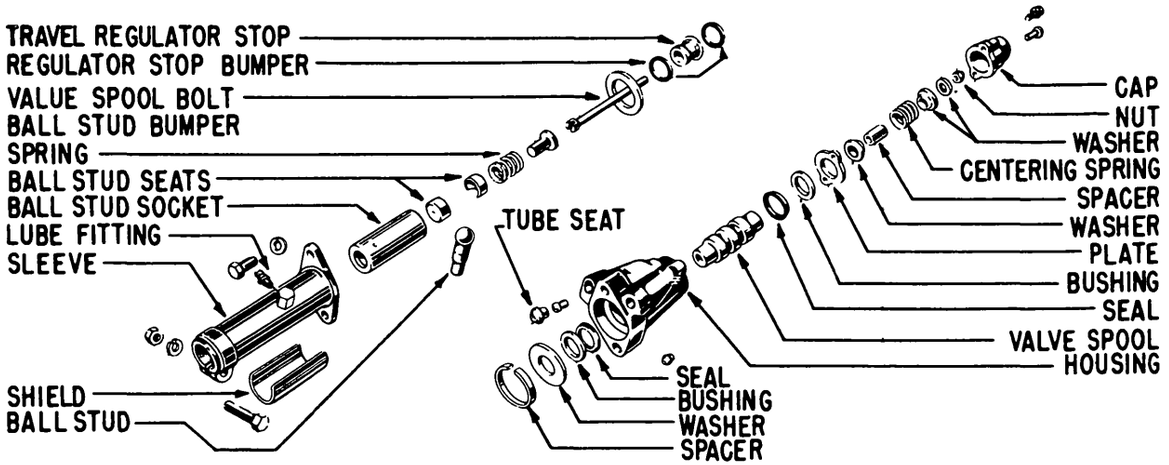
Control Valve—Spool type valve located in end of steering drag link with valve spool directly connected to pitman arm. Valve is actuated by pitman arm (when steering wheel turned) and directs fluid pressure to one end of the power cylinder and at the same time vents the opposite end of the cylinder to the reservoir. Control valve also has a ball check valve in a by-pass passage in the valve housing to permit manual steering with the power off.

Power Cylinder—Double-acting piston type. Piston rod is anchored to frame side rail and cylinder is connected to the drag link so that power application tends to move the drag link in the same direction in which it is being moved by the steering wheel. Cylinder is double-acting (with fluid pressure in one end of cylinder, opposite end is vented to the reservoir through the control valve).

PUMP DRIVE BELT ADJUSTMENT: Nash - Adjust pump drive belt sufficiently tight to prevent slippage.
Packard - Adjust belt to 26-28 ft. lbs. torque. Make sure pulleys are in alignment.

►***ADJUSTMENT CAUTION—Whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units ,etc.) hydraulic system must be bled to remove air. See Bleeding Hydraulic System.***

LUBRICATION: ***CAUTION—Power Steering System and Steering Gear are lubricated separately and with DIFFERENT lubricants as follows:***



Power Steering System: Check fluid level in reservoir at 1000 mile intervals (remove reservoir cover.) Maintain level at 1" below top of reservoir using Automatic Transmission Fluid Type "A"

Steering Gear: Check lubricant level every 3000 miles and maintain even with filler plug hole. Use SAE. No. 90 Steering Gear Oil.

BLEEDING HYDRAULIC SYSTEM: Whenever lines disconnected, or units disturbed, bleed system by making complete right and left power turns, then recheck oil level in reservoir.

TROUBLE SHOOTING: ***If operation not satisfactory, diagnose trouble as follows:***

HARD STEERING: 1) Pump failure, loose or broken belt.
2) Broken or weak relief valve spring, sticking relief valve.
3) Low pump pressure, line leakage, or low fluid in system.

NASH & PACKARD POWER STEERING CONTROL VALVE ASSEMBLY

4) Under-inflated tires.
5) Bent linkage, steering tube mis-alignment, improper wheel alignment.
6) Steering adjustment tight.
7) Improper lubrication.
8) Leakage in power cylinder past piston ring.
9) Air in system.
10) Pump control valve sticking.
11) Control valve spool out-of-round or damaged.

STEERING TOO SENSITIVE: 1) Overinflated tires.
2) Pump pressure too high.
3) Flow control valve stuck in closed position.

LOOSE STEERING: 1) Wheels out of alignment, bearings loose or worn.
2) Loose ball joints, steering knuckle pins, steering gear-to-frame bolts, pitman arm, or lash in linkage.
3) Air in system.

POOR CENTERING: 1). Faulty or binding control valve spool or power cylinder.
2) Control valve spool nut too loose or too tight.
3) Steering misalignment, one tire underinflated, loose wheel bearings.

POOR RECOVERY: 1) Steering gear adjusted too tight, improper caster adjustment.
2) Lack of lubrication of linkage, low tire pressure.
3) Stop nut pin installed in wrong hole causing spool assembly to bind in bore.

PUMP NOISE: 1) Improper fluid level, loose return hose connection, clogged intake line or filter, improper fluid.
2) Pump belt squeal, hose rubbing against other parts, loose pulley, mechanical trouble in pump, relief valve chattering.
3) Wheels held at stops too long, overheating pump.

LOW PRESSURE (When Tested With Gauge):
1) Low fluid level, external or internal leakage.
2) Slipping belt or pump mechanical trouble.
3) Pump relief valve weak or stuck open, flow control valve struck open.

NO POWER ON STEERING GEAR (Engine Running): 1) No pressure at pump. Items 1) to 3) for Low Oil Pressure (above) apply.

CHUCKLE OR RATTLE IN STEERING: 1) Too much back lash in steering, worn or loose parts, ball socket or studs loose.
2) Control valve improperly adjusted.

SHIMMY: 1) Lash in linkage, worn or loose steering parts, wheels out of balance.

OIL LEAKS (PUMP): 1) Loose or defective connections, defective "O" ring seals between reservoir and pump, or between connections.
2) Defective seal on pump shaft or between cover and body, hose leaks.

OIL LEAKS (POWER CYLINDER): 1) Loose or defective connections.
2) Defective seals between cylinder flange and body.
3) Defective spring loaded metal encased seal on shaft, scored shaft.

OIL LEAKS (CONTROL VALVE): 1) Worn seals on end of spool.
2) Drippage of fluid from ball stud section indicates seals on spool are passing fluid.

CONTROL VALVE NOISE: 1) Spool bolt nut loose, causing spool flutter.

STEERING WHEEL DOES NOT CONTROL OPERATION OF POWER STEERING (After Assembly To Car): 1) Improper hose connections.

TESTING HYDRAULIC OIL PRESSURE (NASH): Check reservoir for correct fluid level. If low, fill to proper level with Hydra-Matic Transmission Fluid. Inspect all hoses and connections for evidence of external leaks. Test as follows:

(1) Install Oil Pressure Gauge J-5548 in main oil pressure line at control valve. Start engine, allow oil to circulate for several minutes to warm oil in reservoir.

(2) With car standing on dry, rough concrete, make complete turn in each direction. Observe oil pressure gauge during this operation. Gauge should indicate 450-550 P.S.I. If oil pressure low, pump opera-

CONTINUED ON NEXT PAGE

BENDIX LINKAGE TYPE (NASH, PACKARD) (Continued)

tion or oil leakage is cause. If pressure varies more than 100 P.S.I. in either direction, internal leakage is cause.

(3) Check oil pump pressure output and relief valve operation by disconnecting pressure gauge from control valve and capping pump pressure line so pump will develop maximum pressure. Plug control valve to prevent excessive oil loss. With engine idling, gauge should indicate 700-900 P.S.I. If pressure low or erratic, pump belt may be loose. Watch pump pulley for smooth operation. If pump belt not slipping pump is at fault.

(4) After pump checked and operation satisfactory, reconnect gauge to control valve, disconnect two lines to power cylinder, plug two ports in control valve using special plugs. With engine idling, steer car in both directions observing pressure. Pressure should be 700-900 P.S.I. If pressure low turning one way and correct the other, inspect control valve spool spacer sleeve for correct length (41/64"). Low pressure turning both ways indicates internal leakage in control valve.

(5) If pump pressure check and inspection of control valve shows both units operating satisfactorily, then power cylinder is cause of the difficulty.

TESTING HYDRAULIC OIL PRESSURE (PACKARD): Remove reservoir clamp, cover and gasket, then use a suction pump and remove oil from reservoir. Test as follows:

(1) Disconnect pressure hose at union on right side of pump, install pump pressure Gauge Hose and Valve PK-13 on union at pump with hand valve open. Connect pressure hose to fitting on hand valve side of gauge. Refill reservoir to proper oil level.

(2) Run engine until warmed up, then turn wheels from full right to full left position to bleed air from system. Add oil as required to bring fluid to proper level. After engine warmed up and idled at 375 RPM., wheels should be resting on ground in straight-ahead position. Close gauge hand valve and observe gauge reading. Reading should be approximately 650 P.S.I. Gauge will oscillate several hundred P.S.I. on gauge dial. Center reading will be approximately 650 P.S.I. if pump at maximum efficency. If average reading below 550 P.S.I. pump needs repair. ***CAUTION—Do not keep gauge hand valve closed any longer than necessary to read gauge.***

(3) Turn steering wheel toward either of wheel stops. As wheel is turned from straight-ahead position, pressure will start increasing until it reaches wheel stops where pressure should be 600-650 P.S.I. If pressure less than 600 P.S.I. trouble lies in control valve or power cylinder.

(4) After completing above tests, shut engine off, drain reservoir. Disconnect and remove gauge hose and valve from pump and pump pressure line. Reconnect pump pressure line to pump, tighten hose-to-pump connector. Fill reservoir to level mark with Ultra-matic Drive Fluid, start engine. Turn wheels from full left to full right position several times to bleed system of air. Add oil as required. Check pump pressure line at pump for fluid leakage. Install reservoir gasket, cover, clamp and clamp screw on reservoir, tighten screw.

REMOVAL & INSTALLATION: Proceed as follows:

►***CAUTION—Before removing assemblies thoroughly clean the assembly and surrounding parts to prevent dirt from entering assemblies.***

NASH Control Valve Removal From Car: Disconnect oil pressure and return hoses at control valve and two lines connecting valve to power cylinder. Remove cap and gasket from outer end of control valve, then remove self-locking nut and special washer located under cap. Remove two valve-to-linkage attaching bolts, then remove control valve.

Installation: Slide control valve spacer and control valve assembly on bolt of linkage. Be sure spacer sleeve is in place on special bolt. Install special flat washer and a new self-locking nut on end of bolt at outer end of control valve. Adjust nut until there is just a slight amount of play. NOTE—If nut too tight, spool may bind in housing, if too loose, there will be excessive lost motion before spool moves. Reinstall gasket, cap and oil lines.

PACKARD Control Valve Removal From Car: Remove cotter pin and ball stud nut attaching forward end of pitman arm to control valve. Using tool No. PK-11, Ball Stud Remover, install jaw of tool between pitman arm and ball stud in control valve. If dust cap spring is under jaws of tool, pry it up before inserting tool. After ball stud loosened, push up on linkage to release ball stud and control valve from pitman arm. Disconnect reservoir port hole at left end fitting on control valve. Drain fluid. Cap or plug hose fitting to prevent fluid from dripping and dirt getting into hose line. Disconnect pump port hose at connector on valve (second connection from left end). Disconnect left turn hose at connector on valve (connection farthest to right). Using calipers or a rule measure distance between end of control valve and center of connecting rod ball stud (control valve on reinstallation threaded on end of steering connecting rod to exact position from which removed). Unscrew and remove zerk grease fitting from control valve. Loosen bolt in clamp on end of control valve, turn valve to provide room for tools used for disconnecting hose. Disconnect right turn hose at fitting (center front of valve body). Plug or cap hoses to prevent dripping. Unscrew control valve from end of connecting rod.

Installation: Thread control valve onto end of steering connecting rod. Check measurement with a rule or calipers to make sure valve is in identical position from which removed. Tighten locking clamp bolt to 25-30 ft. lbs. Install zerk fitting. Position control valve ball stud in pitman arm, install attaching nut and tighten to 45-50 ft. lbs. Install new cotter pin. Install hoses, tighten.

POWER CYLINDER REMOVAL: Disconnect hoses at power cylinder. Secure hoses in an upright position and cap or plug ends to prevent fluid from dripping and dirt entering hoses. Disconnect power cylinder from frame bracket and piston rod from steering linkage connecting rod, remove power cylinder.

Installation: To install Power Cylinder reverse removal procedures. Tighten attaching nuts to 45-50 ft. lbs. torque.

OIL PUMP REMOVAL: Disconnect oil lines from pump, drain oil into container. Cap or plug fittings of pump. Release pump belt tension, remove pump belt from pulley. Remove pulley, then pump and reservoir.

Installation: To install pump, reverse removal procedures. Tighten pulley to 15-18 ft. lbs. torque.

CONTROL VALVE OVERHAUL: Disassembly—Mark or scribe control valve housing flange to assure proper reassembly. (Packard) Remove capscrews holding control valve cap and gasket to end of control valve spool housing, remove these parts. Remove nut and washer from valve spool bolt. Remove attaching capscrews holding valve spool housing and adaptors to flange end of sleeve and flange assembly, then separate spool housing, adapters, spool washer and spacer from valve spool bolt. Using small punch, push out pin that locks socket tube, stop screw and valve spool bolt together as unit. Unscrew stop screw from socket tube. Remove ball seat spring, ball seats and ball stud from ball socket tube. Remove socket tube from bore of sleeve and flange assembly. (All) Valve spool bushings have "push fit." To remove spool, use round piece of brass rod slightly smaller in diameter than spool stem, tap lightly until bushing free from spool housing bore. This method may be used at either end of spool housing. After removing bushing and spool, bushing at other end may be tapped out.

Inspection & Cleaning: Inspect packings on inner and outer diameters of valve spool bushing for damage or excessive wear. Inspect lands of spool for nicks and burrs. Clean with crocus cloth if necessary. Inspect valve spool housing bore and adaptor bore for wear, cracks, or scoring. Examine valve spool to see if bent. Check condition of ball seat spring. Replace as required. Wash all parts with carbon tetrachloride or suitable cleaner, blow out passageways with compressed air. Use new packing rings on reassembly.

CONTINUED ON NEXT PAGE

BENDIX LINKAGE TYPE (NASH, PACKARD) (Continued)

Reassembly: Install control valve spool in housing. Using seal guide tools install bushings (large bushing on large stem end of spool). Check movement of spool in housing for free operation. (Nash) Slide control valve spacer and control valve assembly onto bolt of linkage. Be sure spacer sleeve is in place on special bolt. Install and tighten attaching bolts. Install special flat washer and new self-locking nut on end of bolt at outer end of control valve. Tighten nut to provide just a slight amount of side play. (Packard) Install ball seats in ball socket tube, insert assembly into sleeve and flange assembly. Install ball stud and ball seat spring. Slide stop screw over valve spool bolt, tighten stop screw into ball socket tube which has been assembled into sleeve and flange assembly. Back off stop screw to nearest hole and where stop screw lines up with hole in spool bolt and socket tube. If spool bolt can be rotated, install stop screw pin. Install adapters, spool washer, spool spacer on valve spool bolt. Assemble these parts with capscrews to valve spool housing making certain alignment marks are lined up. Tighten capscrews to 25-30 ft. lbs. Install washer and nut on valve spool bolt and tighten nut so that there is just a slight amount of slide play. Center ball stud in socket tube. Check operation of control valve spool in housing by moving stud. Install valve spool body end gasket, cover and capscrews. Torque tighten to 12-15 ft. lbs.

POWER CYLINDER OVERHAUL: Disassembly—Mark or scribe flanges of power cylinder. Remove fluid communication tube from cylinder. Remove adapter assembly from cylinder, then piston rod from bore. Remove scraper washer and seals from adapter and bore.

Inspection & Cleaning: Wash all parts with carbon tetrachloride or suitable cleaner, blow parts dry with air. Inspect cylinder rod end of casting and bore of cylinder body for cracks, dents, wear, broken welds, and excessive scratching. Inspect threads of fittings, examine piston rod to see if bent or threads damaged. Examine ball stud on piston rod for excessive wear and damaged threads. Replace as required. Replace ring packing and seals.

Reassembly: Install seals in adaptor assembly and bore. Install scraper washer. Lubricate piston rod with oil (Hydra-Matic or Ultramatic). With piston rod guide insert piston rod through seals into adaptor housing bore. Install piston assembly in bore (Nash has two rings with end gap .001-.007", sideplay .001-.003". Packard one ring with not more than .016" gap and free movement in groove). Realign scribe marks on flanges, torque tighten attaching bolts to 15-18 ft. lbs. Install oil communcations tube, tighten. Install hoses in fittings of power cylinder, tighten.

POWER STEERING PUMPS: *See "Eaton (Rotor) Type", "Vickers (Vane) Type" or "Saginaw (Vane) Type" pump data under "Power St ring Hydraulic Pumps" for complete data*

STEERING GEAR ADJUSTMENT & OVERHAUL: *S e "Gemmer Worm & Roller' Steering Gears.*

1954-58 MONROE LINKAGE TYPE

D dg 6 (1954)
Huds n (1954-57)
Nash (1954-57)
Packard (1955-56)
Plymouth (1954)
Rambler (1955-58)

DESCRIPTION: Monroe Power Steering is of the "Linkage Type". The power mechanism is built into the steering linkage and is used in conjunction with a standard steering gear. Power steering system consists of the following units:

Hydraulic Pump & Reservoir Assembly: On Dodge and Plymouth, the pump and reservoir assembly is mounted at rear of generator and driven by generator armature shaft. On others, assembly is mounted on engine and is belt-driven by crankshaft. Consists of rotor type pump with built-in relief valve (pre-set to specified limits - See "Testing Hydraulic Oil Pressure' below) A flow control valve limits maximum volume, at high engine speeds, to steering gear requirements

Power Link: Serves as drag link in steering linkage. Double-acting piston type. Piston rod is anchored to bracket on right frame side rail, with tie rods connected to ball studs which are firmly attached to the cylinder of the Power Link. The control valve body is an integral part of the Power Link, and moves with the Power Link cylinder. Precision type spool valve is centered in valve body by springs at either end. Stud, attached to pitman arm, extends through valve body, and can be moved in either direction to change position of valve spool thereby actuating Power Link.

►*ADJUSTMENT CAUTION–Whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units, etc.) hydraulic system must be bled to remove air. See Bleeding Hydraulic System below.*

PUMP BELT ADJUSTMENT: Dodge & Plymouth - Install adjusting tool C-3379 and torque wrench C-3005 Pull torque wrench to 15 ft. lbs torque and tighten adjusting strap bolt and generator-to-generator bracket bolts.

Hudson 6 & Rambler: At proper tension, belt should not deflect more than ¼" with thumb pressure midway between pulleys

Nash & Hudson V8: Tension should be sufficient to prevent slippage.

POWER LINK ADJUSTMENT: When it has been determined that valve spool in Power Link is not adjusted properly, adjustment can be made by turning plug in valve end of Power Link in or out, as required, 1/6 turn at a time. In no case should it be necessary to turn it a total of more than 1/2 turn to have a correct adjustment. Road test car and turn plug **IN** if left turn too hard, right turn too easy, poor recovery after right turns with good recovery after left turns, tendency of vehicle to wander to the right. Turn plug **OUT** if one or more conditions opposite the above exist. Proceed with adjustment of the link valve as follows: Scribe mark on plug in valve end of power link to indicate original position of plug. Remove cotter pin, turn plug in or out 1/6 turn (as determined by symptoms above). If plug held by wire and lead seal, remove seal and after adjustment, replace with cotter pin. Road test vehicle, then if steering action improved but still not correct turn plug an additional 1/6 turn, then road test vehicle again. If necessary, plug can once more be turned an additional 1/6 turn. When steering action is proper, install cotter pin to lock plug in position. If steering action still not correct after plug moved 1/2 of a full turn replace power link.

FRONT END ALIGNMENT: *Se individual car mod l pages or "Suspension & Wheel Alignment" S ction.*

PITMAN ARM STOP SCREW ADJUSTMENT: Proceed as follows.

Hudson (1954) Turn steering wheel to full right turn and place a 1/16" shim between the stop on the right hand outer steering arm and the stop on the spindle support. With shim in place, adjust the stop screw at pitman arm stop bracket until screw just touches pitman arm, then tighten lock nut securely.

HUDSON (1954) DRAG LINK ADJUSTMENT Disconnect drag link at stud which extends through valve portion of power cylinder. Set front wheels in straight-ahead position with steering gear on the high point (steering wheel spokes in horizontal position). If drag link will not enter over stud freely, loosen clamp screw and turn drag link arm in or out as required. After adjustment, securely tighten clamp screw and valve stud nut. *NOTE*–If adjusted properly, drag link and stud fit snugly on power cylinder without bind. It is essential that drag link and stud be able to move a few thousandths inch sideways to operate power cylinder. Maintain the 1.990" plus or minus .010" dimension between inner face of thrust washers. If drag link and stud drawn down too tightly on power link, steering effort will increase and wheels will not return properly after a turn. It may be necessary to disengage drag link from stud and remove one of two metal washers on stud and rubber cushion and the drag link. If this does not correct condition, it may be necessary to replace stud or drag link.

LUBRICATION· *CAUTION–Pow r Steering Unit and Steering Gear are lubricated separately with DIFFERENT lubricants*

Power Steering System: Check fluid level every 2,000 miles (Dodge & Plymouth 1000 miles), maintain at indicated level near top of reservoir (Dodge & Plymouth 1/2" above highest point of filter element). Check for leaks before adding fluid to system. Capacity of system is 3 pints.

Recommended Fluid–(Dodge & Plymouth) SAE 10-W Engine Oil when temperatures consistently above 10° F. above zero, and SAE 5-W when temperatures reach 10° F. below zero and remain consistently below 10° F. above zero. At extreme high temperatures use SAE 30 Engine Oil. (Others) Automatic Transmission Fluid (Type A–AQ-ATF).

Draining System (Dodge & Plym uth): *(NOTE–Extrem care should be exercised to prevent dirt from ntering r s rvoir while cover is removed. To prevent damage to filter elem nt, do not insert sharp objects into reservoir. Do not disturb filter el ment as periodic*

CONTINUED ON NEXT PAGE

1954-58 MONROE LINKAGE TYPE (C ntinued)

chang s of this unit are not requir d.) Disconnect high pressure (small) hose at power steering unit, place end of hose in suitable container. While holding hose in container start engine and allow to idle until all fluid is forced from unit (CAUTION—Do not run engine above idle speed). As soon as fluid starts to show great quantities of air bubbles, stop engine. Reconnect high pressure hose, refill.

BLEEDING (REFILLING) HYDRAULIC SYSTEM (HUDSON): Loosen hose connections at booster cylinder valve; with hoses disconnected at pump, fill hoses with fluid (Type A—AQ-ATF) until fluid runs out at the hose connections at booster cylinder free of air bubbles; then tighten connections at booster cylinder, while keeping hoses full of liquid. Install hose connections at oil pump and tighten securely. Fill oil pump reservoir to mark with recommended fluid. Fill cooling system. Start engine and run at idle speed for approximately 10 minutes to allow hydraulic system to clear itself of air that may be trapped in the system. *(CAUTION—Do not turn the steering wh l during this 10 minute period).* Recheck oil level. Install reservoir gasket, cover, cover attaching screw, flat washer and lock washer (use new gasket). Check all hose connections for leaks. *NOTE*—If oil pump is noisy and fluid level is up to mark in reservoir and all connections are tight, place car in service. Noise will disappear after three or four days usage. Pump noise is caused by air forced into the oil. The air will be gradually dissipated during usage. If care is taken during filling and while connecting hoses, condition should not occur.

BLEEDING (REFILLING) HYDRAULIC SYSTEM (OTHERS): Fill reservoir to within one inch of top (Dodge & Plymouth slightly above normal). Start engine and allow to run for a short time to circulate oil through hoses. With engine running at idle speed, turn steering wheel back and forth several times from extreme positions to bleed any remaining air out of system. Check oil level in reservoir, refill to proper level.

TESTING: If Power Steering operation is unsatisfactory and before making any tests be sure pump belt tension is correct, fluid level proper, leaks eliminated; that wheel alignment, pressure and condition of tires and shock absorbers are satisfactory. Then make tests as follows:

Ste ring Effort: Start engine. With engine running at idle speed (Automatic Transmission in neutral), front wheels on dry, smooth concrete (or smooth steel plates), a 3-10 lb. pull should be sufficient to turn steering wheel one full turn in either direction from center. If otherwise see "Trouble Shooting" below.

Hydraulic Pr ssure (D dge & Plymouth): With engine turned off, connect pressure gauge in pressure line between pump and hose with shut-off valve open. Start engine. If, when turning steering wheel to either extreme position, the gauge does not show 500 lbs. per square inch, slowly close valve. If pressure does not gradually increase as the valve is closed, flow control valve may be stuck in open position or drive coupling may be broken. *(NOTE*—If gauge not available, a fairly accurate way of making test is as follows: Start engine and turn wheel to both extreme positions. If high pressure hose flexes, pump is in good condition. If high pressure hose does not flex, lack of pressure from pump is indicated.) Turn engine off, and remove reservoir cover. Restart engine and turn steering wheel. If oil flows through filter, flow control valve plunger is stuck. Turn engine off and remove gauge. Insert a 1/4" blunt probe against valve plunger. If valve moves inward, it was stuck. Recheck pressure and if gauge registers less than 500 lbs. per square inch, a broken coupling is indicated and must be replaced. Remove pump from generator. If either coupling is broken, turn pump shaft by hand at least ten revolutions. If shaft turns freely, install a new coupling on both the pump and generator shafts. If pump shaft binds when turned by hand, replace both pump and couplings. If generator armature shaft is damaged, replace necessary parts.

Hydraulic Pressure (Others): With engine turned off, connect pressure gauge in pressure line at pump, turn gauge to open position. Start engine and idle for approximately two minutes for fluid to reach operating temperature. With gauge valve open, turn wheels against a curb or other suitable object, maintain sufficient force on steering wheel to keep hydraulic power applied to steering linkage and front wheels. Note pressure on gauge, then release steering wheel. *CAUTION—Do not maintain force on steering wheel for any extended period of time to avoid undue wear in hydraulic system.* If pressure noted was 500-800 psi., power link and pump are operating properly and it is unnecessary to continue further. If less than 500 psi. close gauge valve and note pressure developed by pump, then open gauge valve. *CAUTION—Do not leave gauge valve closed for more than 3 or 4 seconds.* If pressure developed by pump increase to 500-800 psi. (650-900 psi. Nash, Hudson & Rambler V8) fault is in Power Link. Check pitman arm for binding on valve body. If pitman arm not binding, remove Power Link piston and rod assembly. Check piston and rings, replacing parts as necessary. Reinstall Power Link, then make another pressure check, and if pressure is still low, replace Power Link. If pressure does not increase to 500-800 psi (650-900 psi, Nash, Hudson & Rambler V8), replace relief valve spring and flow control valve spring. If pressure still low, pump must be removed and overhauled. If pressure ever exceeds 800 psi. (900 psi Nash, Hudson & Rambler V8), replace relief and flow control valve unit.

TROUBLE SHOOTING: *Diagnose trouble as follows:*

Hard Steering in Both Directions: 1) Leak in system, fluid level low, insufficient fluid flow in system due to plugged flow restrictor or hoses.

2) Steering gear and linkage not lubricated, pitman arm and stud binding on power link, bend in power link piston rod, bind in steering column or gear.

3) Low pump pressure caused by stuck relief and flow control valve, weak or broken flow control valve spring, weak or broken relief valve spring, rotors not turning, rotors worn, pump body or cover worn.

4) Loss of pressure in power link caused by internal fluid leak past piston or valve.

5) Valve in power link misaligned or sticking.

6) Tire pressure too low, improper front end alignment.

7) Pump belt slipping or broken.

Hard Steering in one Direction Only: 1) Valve in power link misaligned or sticking.

2) Tire pressure too low, improper front end alignment.

3) Bend in power link piston rod, bind in steering column or gear.

Poor Recovery on Turns: 1) Tire pressure too low, improper front end alignment.

2) Pitman arm and stud binding on power link, bind in steering column or gear, bind in steering knuckles.

3) Bend in power link piston rod, or valve in power link misaligned or sticking.

Vehicle Attempts to Turn unless Force Applied to h ld Steering Wheel: 1) Tire pressure uneven.

2) Pitman arm and stud binding on power link.

3) Valve in power link misaligned or sticking.

Noise: 1) Pump belt tension is incorrect, pump drive pulley retaining bolt loose, pump drive pulley key does not fit, pump shaft bearing worn, worn bushings in pump body or cover.

2) Low fluid level, dirt and sludge in pump.

3) Pitman arm stud loose, tie rod clamps tightened in wrong position, power link bracket on frame hitting lower suspension arm.

4) Restricted air vent in reservoir cover.

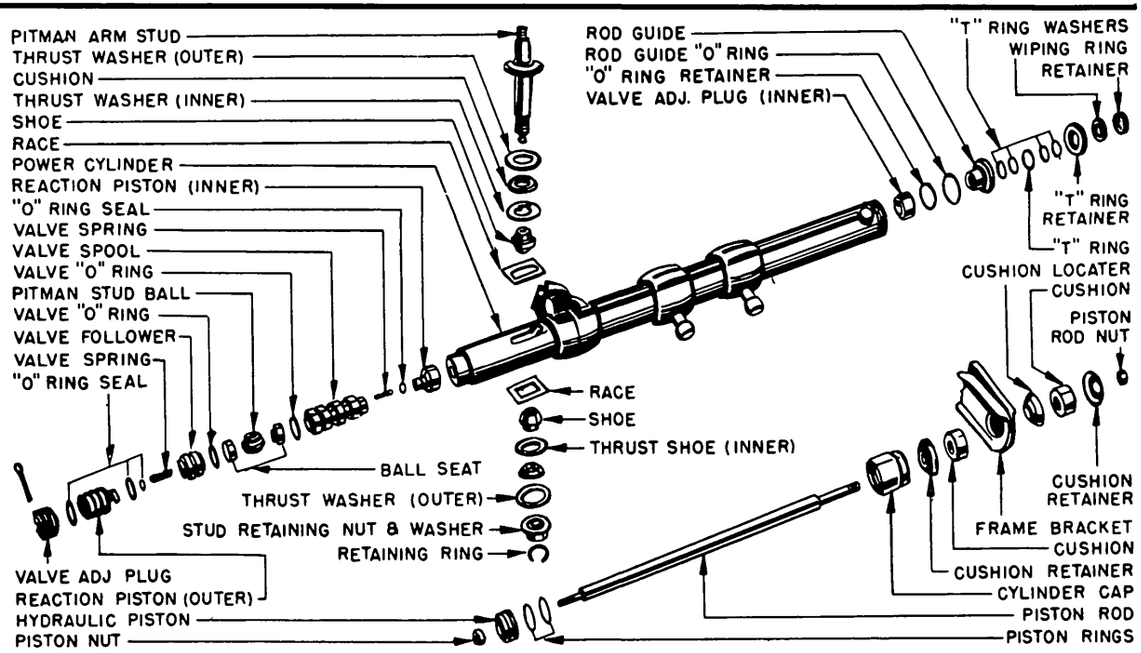
5) Noise in power link valve.

REMOVAL & INSTALLATION OF VALVE & POWER CYLINDER (POWER LINK): Proceed as follows:

Dodge & Plymouth: Raise vehicle (preferably with hoist). Remove right and left tie rod ends at steering knuckle arms. Place drain pan beneath power unit at hose fittings. Disconnect hoses, plug hose fittings and cap fittings on unit. *(CAUTION—After fittings n unit have been capped, care should be exercis d to prevent movement of the unit on piston rod. If steering wheel is turned or if other force is put on unit, seals can be blown. Do not start engine after removing hoses and putting plugs in lines.)* Disconnect power unit from steering arm at steering arm attaching stud. *(CAUTION—Power steering unit should b prevented from dropping by either holding or tying in place. Tap on steering arm, not on attaching stud and do not pry between valve and steering gear arm).* Holding piston rod at flat section with 9/16" open end wrench, remove piston rod attaching nut. Remove outer linkage bracket cushion retainer and cushion. Disconnect piston rod from frame bracket. Remove tie rods from power unit if necessary and replace before installing in vehicle. To install, reverse removal procedure. Tighten nuts to 45-75 ft. lbs. torque. Check oil level in reservoir and refill (see Lubrication above) as necessary.

Hudson (1954): Turn front wheels full left. Remove cotter pin from drag link ball stud at valve shaft and remove castle nut (7/8" wrench). Remove drag link ball stud from valve stud, using Tool J-2781. Remove

CONTINUED ON NEXT PAGE



1954-58 MONROE LINKAGE TYPE (C ntinued)

cotter pin, end plug, safety plug, spring and ball seat, then disconnect valve and cylinder from center steering arm. Raise car and place on stand jacks. Disconnect piston rod at support bracket at No. 3 crossmember by removing cotter pin and lock nut (3/4" wrench) and push the piston rod through bracket and remove piston shaft washers, rubber bushings and retaining washers. Disconnect hoses at oil pump and lift valve and power cylinder up through engine compartment. To install, connect piston to frame bracket and tighten castellated nut until **two full threads** of piston rod extend beyond top of nut. (DO NOT exceed this limit). Assemble drag link onto valve stud and install nut and cotter pin. Tighten drag link arm-to-valve stud nut to 50-60 ft. lbs. torque, then tighten other valve stud nut to give equal compression of rubber cushion against power cylinder. It is essential that valve and drag link are able to move a few thousandths of an inch sideways to operate power cylinder spool valve. (CAUTION—Maintain the 1.990" plus or minus .010" dimension between inner face of thrust washers. If this dimension not held, drag link and stud may be drawn down too tightly on power cylinder, increasing steering effort so that wheels will not return properly after making a turn. Install washers in sequence (reverse to that in which removed). It may be necessary to remove one of metal thrust washers to correct an overtight condition). Assemble steering arm ball (center) into slot in unit and install ball seat, spring and spring seat plug. Install hoses, but do not tighten. Fill hoses with fluid until fluid runs out at hose connections at booster cylinder free of air bubbles, then tighten connections at booster cylinder, while keeping hoses full of fluid. Install hose connections and tighten securely. Refill system

Hudson (Exc. 1954), Nash & Rambler: Disconnect oil hoses from unit and disconnect rod from side sill bracket. Disconnect tie rods from cylinder and valve assembly. Remove putman arm stud adjusting nuts, washers, cushions and spacers and remove cylinder and valve assembly from pitman arm. To install, reverse removal procedure. Tighten inner nut on pitman stud until there is sufficient tension on rubber cushions to prevent rattles and grease leakage and still permit free movement of the stud.

VALVE & POWER CYLINDER (POWER LINK) OVERHAUL: Valve Disassembly: Remove valve and power cylinder assembly from vehicle (See Removal & Installation above), then proceed as follows:

Dodge & Plymouth - Clean outside of the valve and cylinder assembly in suitable solvent. Remove cotter pin from outer adjusting plug. Using a scribe, mark the location of the adjusting plug (to assist in making final adjustment *(CAUTION–Do not use center punch for marking)*. Count number of turns, turning adjusting plug in until it bottoms, and record. *(CAUTION–Do not bottom adjusting plug unless attaching stud has been left assembled through ball, otherwise damage to ball may result from crushing.)* Remove outer adjusting plug. Note air vent in plug to see that it is open. Disassemble and remove steering arm stud. Using attaching stud, or brass rod, inserted through steering arm ball pull the right turn (outer) reaction piston, spring, follower and ball seat toward outer end of valve bore as far as possible. Remove attaching stud and ball. Insert finger in valve bore and push out assembly. Remove valve spool by tapping valve end on wooden bench or block of wood. Remove spring and left turn (inner) reaction piston.

MONROE LINKAGE TYPE POWER STEERING UNIT (TYPICAL)

All Other Models - On Hudson, disconnect hoses and remove cotter pin and outside spring seat plug to disconnect unit from center steering arm. All cars, clean outside of valve and cylinder assembly thoroughly. Punch mark adjusting plug to insure accurate reassembly, remove plug, then remove the valve spring, follower (or retainer), ball and ball seat. Hold unit in vertical position and tap valve end lightly on wooden bench or block to allow valve spool to slide out of valve body. Remove inside valve spring. *NOTE*–Inner adjusting plug cannot be removed.

Cylinder Disassembly: Remove cylinder cap (or unscrew cylinder plug) from cylinder. Pull out on piston to remove piston and guide assembly. To disassemble rod guide, use a screwdriver to separate "T" ring retainer from rod guide, then remove two outer phenolic rings, "T" ring and two inner phenolic rings. Remove large "O" ring from piston rod guide and discard. Disassemble "T" ring retainer only when wiper needs replacement. If necessary, use a screwdriver and remove wiping ring from "T" ring retainer. To reassemble rod guide, reverse removal procedure (lubricate rings with Lubriplate

Inspection: Thoroughly clean all parts in suitable solvent. Remove "O" rings and discard. Inspect all parts for nicks, scores, and burrs. (NOTE–Valve spool not replaceable as separate item, due to close fits). Small scores and burrs can be removed with crocus cloth, if used carefully. Make sure rings rotate freely in piston ring grooves.

Valve Reassembly (Dodge & Plymouth): Reverse the removal procedures. Lubricate new "O" rings with Lubriplate or equivalent. To facilitate assembly, place inner reaction piston spring in recess in spool and hold with Lubriplate or equivalent. Back off adjusting plug same number of turns as recorded when valve disassembled. Check valve assembly operation by placing a long pin through ball, you should be able to slightly move valve assembly back and forth in bore. Do not install cotter pin until unit has been installed in vehicle and power link adjustment checked.

Valve Reassembly (Other Models): Reverse removal procedures. Lubricate rings with Lubriplate or equivalent. Line up adjusting plug punch marks made at disassembly.

Cylinder Reassembly: Reverse removal procedures. Lubricate rings with Lubriplate or equivalent. Be sure rings locked in position and staggered. Wet "T" ring seals with power steering fluid.

POWER STEERING PUMPS: Different pumps used as follows:

Dodge & Plymouth (1954): *See "Chrysler, D Soto, Dodge & Plymouth Single Rotor"*

Hudson & Nash (1954): *See "Vick rs Van Type" (3-Piece Housing).*

Hudson & Nash (1955-57): *See "Eaton Rotor Type".*

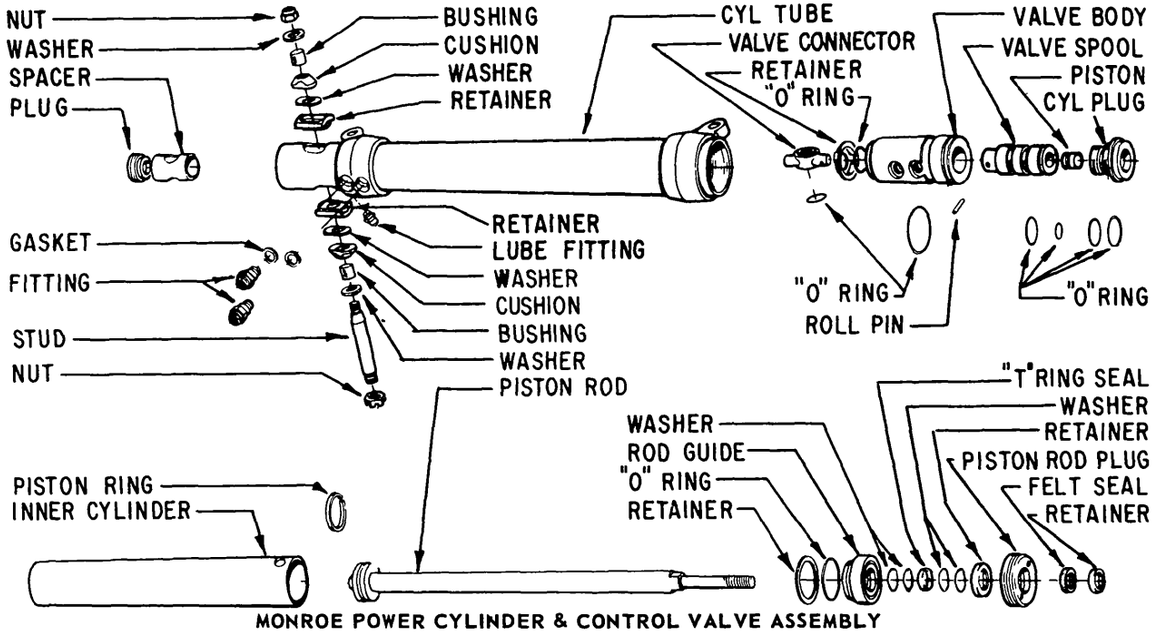
Packard (1955-56): *See "Vick rs Vane Type". (3-Piec Housing).*

Rambler (1955-58): *See "Eaton Rotor Type".*

1959-60 MONROE LINKAGE TYPE

Rambl r, All M d ls (1959-60)

DESCRIPTION: Linkage type with control valve and power cylinder assembly combined in a single unit which is connected to frame side member, tie rods and to steering pitman arm



FRONT WHEEL ALIGNMENT: *See "Front Suspension" on Car Model pages*

ADJUSTMENT: Valv Spool Centering - *NOTE - This adjustment is preset at the factory and is not ordinarily required in service* An improperly adjusted valve spool will be indicated by hard steering in one direction and easy steering in opposite direction Recovery will be poor from direction of easy steering and good from direction of hard steering Car will also have a tendency to wander in direction of easy steering To adjust, turn piston rod end plug OUT and turn pitman arm end plug IN the SAME amount (approximately ½ turn at a time) to correct for hard turn to LEFT, easy turn to RIGHT, poor recovery from RIGHT turn, or car wander to RIGHT Turn piston rod end plug IN and turn pitman arm end plug OUT the SAME amount (approximately ½ turn at a time) to correct for hard turn to RIGHT, easy turn to LEFT, poor recovery from LEFT turn, or car wanders to LEFT After final adjustment, tighten end plugs to 50 ft lbs

PRESSURE TEST: With fluid level in reservoir correct, install oil pressure gauge J-5548-A in main oil line at control valve assembly, then start engine and bring oil to normal operating temperature. Turn wheels against curbing or other obstacle and hold tension on wheel. Oil pressure should be 800-900 lbs. (Roller Type Pump), 850-950 lbs. (Slipper Type Pump). Turn wheel in opposite direction and note pressure. If there is a variation between right and left turns, internal leakage is evident. If pressure is low, stop engine and disconnect gauge from cylinder and valve assembly and cap pressure line. Restart engine and note pressure. If pressure is within specifications, pump is operating properly If pressure is low (belt tension correct), trouble exists in pump. *CAUTION - Do not hold wheels at maximum pr ssur longer than is necessary to obtain a st ady pr ssur reading.*

TROUBLE SHOOTING: Hard Steering or Lack of Suffici nt P w r Assistance - Bent piston rod Low oil pump pressure Insufficient oil flow in system Internal leak in control valve Internal leakage in cylinder Front wheel alignment incorrect Steering knuckle pins binding or steering linkage too tight Steering gear adjustment too tight Binding valve spool in control valve Pitman arm stud binding

Lack f P w r Assistanc in On Dir cti n: Steering gear binding Bent piston rod Valve in cylinder and valve assembly incorrectly adjusted Front wheel alignment incorrect

MONROE POWER CYLINDER & CONTROL VALVE ASSEMBLY

Car Wanders from Straight Ahead (without force on steering wheel): Pitman arm stud binding on cylinder and valve assembly Valve of cylinder and valve assembly not properly adjusted or binding

Poor Recovery From Turns: Piston rod bent Front wheel alignment incorrect Valve in cylinder and valve assembly not adjusted properly or binding

Noisy Operation: Pump pulley shaft key loose Restricted air vent in reservoir cover Pump bearing or bushings worn Dirt in pump Loose pitman arm stud may be cause of rattle

Front Wheel Shimmy: Pitman arm stud loose

REMOVAL: Disconnect oil lines, then disconnect piston rod from frame side member, and tie rods from cylinder and valve assembly Remove pitman arm stud nut and roll pin, washer, cushion, and spacers Remove cylinder and valve assembly from pitman arm stud

INSTALLATION: Reverse removal procedure and bleed system by turning steering wheel several complete turns in both directions with power steering pump operating *NOTE - Wheels must be raised off floor when bleeding system*

DISASSEMBLY: Mount cylinder in a vise in a horizontal position, using tie rod mounting pad to hold cylinder in vise *CAUTION - Do not clamp rounded area of cylinder in vise* Mark piston rod end plug locations in cylinder before disassembly *CAUTION - Marking th plug location is very important to properly center th valve spool when reassembling the unit* Remove cylinder end plug, then remove piston rod and inner cylinder assembly by carefully pulling piston rod assembly from cylinder Remove inner cylinder end plug (if it came out with piston rod assembly) *NOTE - End plug is a light press fit in inner cylinder* If felt dirt seal in piston rod end plug is to be replaced, lift out the old retainer and seal with a screwdriver *NOTE - For replacement, a new seal only should be used Install new seal flush with surface of plug, using Tool J-5619, which will not damage raised inner surface of seal retainer* Remove "O" ring, washers, and "T" ring from piston rod guide If necessary, remove piston ring from piston Remove plug on valve end of inner cylinder, then remove spacer Remove pressure and return line fittings and copper gaskets from cylinder tube assembly Press valve assembly out of cylinder toward piston rod end of cylinder *NOTE - A piece of seamless steel tubing 1 3/8"-1 1/2" I D approximately 18 gauge wall thickness, 22" long, may be used to press out valve assembly* To disassemble valve spool, remove roll pin between valve connector and valve spool, and remove connector Remove inner cylinder end plug (if it did not come out with inner cylinder assembly) Remove retainer cap from valve body and push valve spool out opposite end, then remove inner "O" ring from valve body *CAUTION -*

CONTINUED ON NEXT PAGE

1960 MONROE LINKAGE TYPE (C ntinued)

Valve spool must be removed in this direction to prevent cutting the "O" ring Remove valve piston from valve spool Apply air pressure to small hole near piston end of spool to aid in removal of spool *CAUTION - Remove all 'O' rings and replace with new rings when disassembling unit Lubricate all "O" rings with Lubriplate at reassembly*

REASSEMBLY: Install piston into valve spool,then install valve spool in valve body (see illustration) *CAUTION - If valve spool is assembled in wrong direction, the "O" ring seal could be cut in passing over valve spool inner passages* Install retainer, then install valve connector assembly with the roll pin Center roll pin in mounting so pin does not scrape during operation *CAUTION - Be careful not to push valve spool assembly out of position while installing roll pin* Reassemble piston rod and inner tube assembly (see illustration), noting that hole at end of inner cylinder must be assembled toward end of outer cylinder Reassemble inner components into outer cylinder, lining up pressure and return ports in valve assembly with corresponding holes in cylinder *NOTE - For final assembly, ports may be lined up with a fibre rod* Install piston rod end adjusting plug, tightening it into the previously marked position Install spacer and pitman arm end adjusting plug, holding spacer from turning while tightening end plug to 50 ft lbs Install pressure and return line fittings using new copper gaskets Tighten fitting to 17 ft lbs Install pitman arm components (see illustration), then tighten stud nut until there is sufficient tension on rubber cushions to prevent rattles and grease leakage and still permit free movement of stud *CAUTION - Overtightening stud nut will cause poor recovery from turns and binding when turning Looseness may result in wheel shimmy* With stud correctly adjusted, install locking roll pin Install unit in car

HYDRAULIC PUMP: *See "Vickers Vane Typ ', "Eaton Roller Type" or 'Rambler Slipper Type' Power Steering Pumps*

ROSS LINKAGE TYPE

Dodge V8 (1954)

DESCRIPTION: Ross "Hydrapower" hydraulic, linkage type power unit (power cylinder and control valve assembly). Power unit is an integral part of the steering linkage and transmits steering wheel motion to the wheels mechanically which permits manual steering when hydraulic power not available.

►*ADJUSTMENT CAUTION: Whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units, etc.) hydraulic system must be bled to remove air. See Bleeding Hydraulic System below.*

BELT ADJUSTMENT: *CAUTION–Pump is driven by fan belt and belt should be checked frequently and adjusted exactly as follows.* Use special tool C-3379 with a torque wrench. Hook tool over generator frame at the adjusting strap bolt lug, loosen strap bolts and bracket bolts, pull outward on torque wrench until indicated torque is 15 ft. lbs., tighten adjusting strap bolts before slackening off on wrench, tighten bracket bolts.

OTHER ADJUSTMENTS: No adjustments required in service.

►*STEERING GEAR ADJUSTMENT NOTE:* If steering gear chuck replaced due to accident or extremely high mileages, make check as follows. Remove chuck from vehicle. Torque required to rotate wheel (with scale pulled 90° to spoke of wheel at rim) when roller tooth (steering gear arm) shaft is not assembled in housing, should be 1-4 ozs. with no endplay in bearing. Then, after roller tooth shaft has been assembled, additional pull is required, making a total of 6-10 ozs. pull at rim to rotate steering wheel through mid-position, with no backlash in the worm and roller shaft at that point.

FRONT END ALIGNMENT: Same as for Manual Steering Gear. *See "Front Suspension" on Car Model Page.*

LUBRICATION: *CAUTION–Power Steering System and Steering Gear are lubricated separately and with different lubricants as follows:*

P w r Ste ring Syst m: Check fluid level in reservoir every 1000 miles, add fluid to maintain correct level. **Ch cking Fluid L v l**–If dipstick provided in reservoir cover, maintain fluid level at mark on dipstick. If no dipstick provided, thoroughly clean top of reservoir, remove cover, maintain fluid level at least 1/2" above filter element in reservoir. Use SAE 10-W engine oil (5-W for temperatures consistently below 10°F).

Draining System–*CAUTION–Extreme care should be taken to prevent dirt from entering reservoir while cover is removed. To prevent damage to filter element, do not insert sharp objects into reservoir. Do not disturb filter element as periodic changes of this element are not required.* Disconnect high pressure (small) hose at booster. Place hose in suitable container. While holding hose in container start engine and allow to idle until all fluid is forced from unit. *(CAUTION–Do not run engine above idle speed).* As soon as fluid starts to show great quantities of air bubbles, stop engine. Reconnect high pressure hose.

Refilling System (after units removed or disconnected)–Fill reservoir to higher level than normal. Start engine and allow it to idle for short time to circulate oil through system. With engine idling, turn steering wheel through entire travel (from extreme right to extreme left) several times to bleed air out of system. Check oil level in reservoir, add oil as necessary. **Capacity**–3 pints.

Steering Gear: Same type as used on cars without power steering and lubricated similarly.

BLEEDING HYDRAULIC SYSTEM: With engine running at idle speed, turn steering wheel back and forth several times from extreme right to left to bleed any air out of system. Check oil level in reservoir. Add oil as necessary to bring level to "Full" mark.

TESTING: Should lack of steering assistance be encountered and other checks have been made (See Trouble Shooting below), a pressure check should be made to determine if pump is at fault.

Hydraulic Pressure Check: 1) Connect gauge C-3102 in pressure line between pump and hose with shut-off valve on gauge in open position. Start engine and turn steering wheel. If gauge does not show at least 400 lbs. pressure when steering wheel is in either extreme position, check pump by turning valve of gauge to closed position. If pressure does not gradually increase as valve is closed, flow control valve in pump may be stuck in open position, or drive coupling may be broken. See step 2) below. If 400 lbs. pressure does show on gauge with engine idling, pump is in good condition (Look for trouble as indicated in Trouble Shooting below). Remove gauge and connect high pressure hose to pump.

2) Remove cover from reservoir, start engine and turn steering wheel. If oil flows through filter, a stuck flow control valve plunger is indicated. Shut off engine, remove high pressure hose at pump fitting and insert a 1/4" clean, blunt probe against valve plunger. If plunger moves inward 3/16-1/4", plunger was stuck and will probably function properly next time.

3) Recheck pressure. If it still registers less than 400 lbs. and if oil still flows through filter but does not flex pressure line, remove flow control valve plunger and clean thoroughly. If this does not correct condition, install a new pump assembly.

4) If oil does not flow through reservoir filter in above test, a broken coupling is indicated. Remove pump from generator. If either coupling is broken turn pump shaft by hand at least ten revolutions. If shaft turns freely, install new couplings on both pump and generator shafts. If pump shaft binds when turned by hand, replace both pump and couplings. If generator armature shaft is damaged, replace necessary parts. *(CAUTION–*Service package, Part No. 1450759 has been made available to prevent mixing of new coupling Part No. 1552859 with OTHER couplings in field). Reinstall pump on generator.

TROUBLE SHOOTING: *Diagnos trouble as follows.*

Hard Steering in Both Dir cti ns: Leak in system, pump belt slipping or broken, fluid level low, steering gear and linkage not lubricated, tire pressure too low, anti-roll bracket and pin binding, bend in power unit piston rod, low pump pressure, loss of pressure in power unit, insufficient fluid flow in system, bind in steering column or gear, improper front end alignment, valve in power unit sticking.

Small r Turning Radius in On Dir cti n: Wheel stops not adjusted properly.

CONTINUED ON NEXT PAGE

ROSS LINKAGE TYPE
(Continued)

Hydraulic Fluid Leaks (Locations): At hose adapters, pump body, valve assembly, valve spool assembly, reservoir cover gasket; around piston rod on power unit; between control valve body and cylinder head.

Hard Steering in One Direction Only: Tire pressure too low, bend in power unit piston rod, bind in steering column or gear, improper front end alignment, bind in control valve assembly.

Poor Recovery on Turns: Tire pressure too low, bind in valve assembly, bind in steering column or gear, bind in steering knuckles, bend in power unit piston rod, improper front end alignment, anti-roll pin and bracket binding.

Noise: Fan belt tension incorrect, low fluid level, pump shaft bearing worn, bushings worn in pump body or cover, dirt and sludge in pump, reactor link loose, tie rod clamps tightened in wrong position, steering gear arm adapter to valve spool loose or worn, steering gear arm nut loose, frame bracket cushion retainers striking frame bracket, position of clamp interfering with left tie rod.

REMOVAL & INSTALLATION: Proceed as follows:

Reactor Link Assembly (Unit in Car): Removal–Raise vehicle (preferably with hoist). Remove tie rods from reactor link assembly by removing cotter pins and nuts holding tie rods to threaded ends of the reactor link ball studs. Note position of clamp assembly (to prevent interference on turns), then loosen. Remove reactor link-to-cylinder mounting bolt and lockwasher. Lift reactor link assembly over dowel ring (at mounting bolt end) and slide out of cover reducer end of control valve assembly. *NOTE–Dowel ring may remain in link or cylinder.*

Installation–Place dowel ring in position in cylinder. Install tie rod dust seals and lubrication fittings into reactor link assembly. Install clamp assembly (if removed), then slide reactor link assembly into cap reducer end of the control valve assembly, and position over dowel ring. Install mounting bolt and lockwasher, torque to 45-55 ft. lbs. Position clamp assembly for maximum clearance with tie rod ends, torque to 15-20 ft. lbs. Lubricate fittings and road test.

Power Steering Assembly: Removal–Raise vehicle (preferably on a hoist). Place drain pan beneath power unit at hose fittings, disconnect both hydraulic lines (pressure and return) from power unit. Remove tie rods from reactor link assembly by removing cotter pins and nuts which hold tie rods to threaded ends of the reactor link ball studs. Disconnect piston rod boot at frame bracket end. Holding flattened section of piston rod with 9/16" open end wrench, remove piston rod-to-frame bracket retaining nut. Remove outer linkage bracket cushion retainer and cushion, disconnect piston rod from frame bracket. *(CAUTION–*Booster unit should be prevented from dropping by either holding or tying in place). Disconnect steering gear arm from steering gear arm adapter by removing cotter pin and nut. *(CAUTION–*Tap on steering gear arm and not adapter stud). Remove unit. Then proceed with Bench Operation below.

Installation: Reverse removal procedures.

OVERHAUL: *CAUTION–*Cleanliness through all phases of overhaul cannot be overemphasized.

Disassembly of Power Steering Unit Assembly (Into Major Components): Note position (to prevent interference on turns) of clamp assembly on reactor link then loosen nut. Remove reactor link mounting screw and lockwasher and slide link assembly from end cover. Remove dowel from cylinder. Scribe a line across valve body and cylinder head to show position of parts when reassembled. *(CAUTION–*There is only one correct position of control valve on cylinder head which will permit proper alignment of the four oil passages. Should valve be incorrectly assembled, unit will not function). Remove the four valve body-to-cylinder head mounting bolts, nuts and lockwashers and separate valve body from cylinder. Note two different length bolts used. Power Unit is now set up into three serviceable items–Reactor Link Assembly, Control Valve, and Power Cylinder. Disassemble these components and inspect as follows:

Reactor Link Assembly–Assembly is self-contained unit. Check ball studs for wear. If studs are loose in ball sockets, replace reactor link assembly.

Control Valve–*NOTE–*Since this unit works in oil during operation, very little wear is anticipated on any of moving parts. The major component parts of valve are machined to very close limits and selectively fitted. Use extreme caution when handling these parts as damaged sealing edges or burrs will not permit unit to function properly. It is not practical to service valve body or spool separately. Because of their selective fit and difference in size, gland and reaction rings will be referred to as **Left** and **Right.** This identification has reference to position of parts relative to their position in the vehicle and **not** to the direction of steering wheel turn. These parts are not interchangeable. **Always note their position when disassembling** so their position is not changed when reassembling. The largest gland and reaction ring are the parts for the left side and **must** be installed in the steering gear arm end of the valve. Glands and reaction rings are serviced in matched sets. Disassemble as follows: Using screwdriver or punch, unlock end cover caps by straightening lock ring tabs. Unscrew and remove both end covers from valve body. *(CAUTION–*Use extreme care so as not to damage mating surfaces on valve body when removing caps. Also the use of a strap wrench will prevent damage to exterior finish of caps). Remove lock rings. Remove right gland and spring by slightly pushing on threaded end of valve spool. Remove "O" ring from end of valve spool (end from which gland was just removed). Remove left gland and spring by pulling on threaded end of valve spool. When removing spool, one reaction ring will probably remain in valve body and can easily be removed. The other ring remains on spool. Remove remaining "O" ring and reaction ring from valve spool. Match reaction rings with their respective glands. Remove "O" rings from glands.

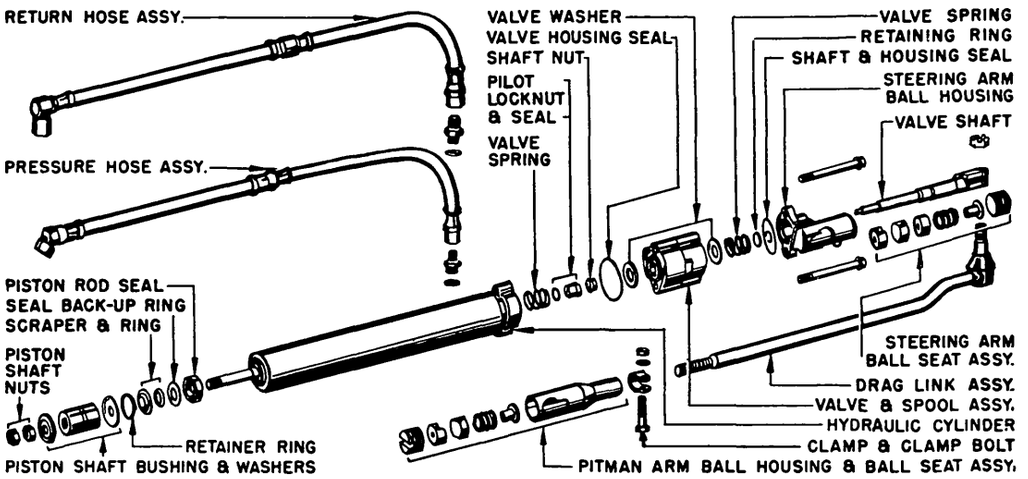
Cylinder–Drain oil from cylinder assembly by moving piston rod in and out from one extreme end of its travel to the other. Remove four "O" ring seals from cylinder head. Note position of piston rod bearing retainer snap ring in end of cylinder (retainer locks snap ring into position). Using punch, straighten tang on retainer and remove snap ring with tool C-3106. Remove piston, rod, bearing and seal assembly from cylinder. *(CAUTION–*Do not clamp or mark sealing surface of piston rod as damage will result to seals. When removing parts from piston rod, always slide them off piston end of rod). Holding piston rod at flattened section at frame bracket end of piston rod, remove cotter pin, nut and backup washer (steel). Remove piston and rings, piston rod bearing, and "O" ring seal from outer diameter of bearing. Remove oil seal from inside of bearing. Remove piston rod bearing backup washer (steel). Remove plastic shims (Note number removed). Slide piston rod seal retainer and spline seal from piston rod.

Reassembly: Reverse disassembly procedures and note the following: Adjust amount of endplay between piston rod bearing retainer snap ring and bearing seat in cylinder to a maximum of .005" by installing plastic shims. Shims are available in thicknesses of .005", .010", .015".

POWER STEERING PUMP: *See "Chrysler, DeSoto, Dodge, Plymouth Single Rotor Type".*

SAGINAW LINKAGE TYPE

Hudson Hornet, Model 7D (1954)



DESCRIPTION: Hydraulic linkage type. Power unit is a complete assembly with control valve built-in the end of the hydraulic power cylinder. The unit is connected in the steering linkage between the drag link and the center steering arm on the frame front cross-member (drag link connected to spool valve stem, center steering arm connected directly to same end of power cylinder) so that steering wheel motion is transmitted to the wheels mechanically to permit manual steering when hydraulic power is not available. Power unit piston rod is attached to a bracket on the frame so that hydraulic pressure tends to move the hydraulic cylinder on the stationary piston. Hydraulic application is controlled by the spool valve which is connected directly to the drag link.

Hydraulic Pump & Reservoir Assembly: Vickers vane type hydraulic pump. *See "Vickers & Eaton Hydraulic Power Pumps" in Power Steering Section*

BELT ADJUSTMENT: Loosen two bolts attaching pump to mounting bracket, move pump upward until belt deflection midway between fan and pump pulleys is ¼" with thumb pressure, tighten attaching bolts to 25-30 ft. lbs.

POWER CYLINDER ADJUSTMENT: Remove Power Cylinder Assembly (See Removal & Installation below). Clamp head of valve shaft in vise so that shaft is in a vertical position. While holding spool shaft nut, remove pilot lock nut and loosen shaft nut. Tighten shaft nut until a definite resistance is met, then back off nut ½ turn. A minimum of 5/16" thread should be showing beyond nut. (*NOTE*—If there is less than 5/16" thread, the inner valve washer has caught on the spool shoulder and is not centralized on valve shaft). After determining that 5/16" dimension is correct, screw on pilot lock nut **by hand**. Using the two valve body-to-cylinder attaching screws and two 3/8"-16 nuts, assemble the valve body and shaft assembly together (tighten to 12-15 ft. lbs. torque). Tighten valve shaft nut to 9-11 ft. lbs. torque. Release tension and tighten to 3-5 ft. lbs. torque. While holding valve shaft nut against turning, tighten pilot lock nut to 5-10 ft. lbs. After final tightening, use a fine punch and working through one of the small holes in the pilot lock nut, make a punch mark to stake lock nut to valve shaft. Place power cylinder on valve assembly and install attaching screws (dip threads in sealer). (CAUTION—Do not gouge or slice pilot lock nut seal when assembling cylinder to valve assembly). Tighten valve housing attaching screws to 12-15 ft. lbs. torque. Install valve fittings and seals in their proper places. Assemble pressure and return hoses to their proper fittings on valve body assembly. Install assembly on car (See Removal & Installation below).

STEERING LINKAGE ADJUSTMENTS: Pitman Arm & Stop Screw—Turn steering wheel to full right hand turn, place a 1/16" shim between stop on right hand outer steering arm and stop on spindle support. With shim in place, adjust stop screw at pitman arm stop bracket until screw just touches pitman arm, then tighten lock nut securely.

SAGINAW LINKAGE TYPE POWER STEERING UNIT

Drag Link—Set front wheel in straight-ahead position with steering gear on high point (steering wheel spokes in horizontal position). Drag link stud should hole in valve shaft freely. If not, disconnect drag link at pitman arm, loosen clamp at junction of male and female connection of drag link and turn drag link in or out as required. After adjustment, tighten clamp screw securely. Adjust drag link end plug by tightening plug to end of travel and back off to nearest cotter pin hole. Install and secure cotter pin. Install drag link, nut and cotter pin to valve shaft.

LUBRICATION: *CAUTION—Power Steering System and Steering Gear are lubricated separately and with different lubricants:*

Power Steering System: Check fluid level in reservoir every 2000 miles, add fluid to maintain level.

Checking Fluid Level—Thoroughly clean top of reservoir, remove cover, maintain fluid level even with mark near top of reservoir. Use Automatic Transmission Fluid Type A.

Refilling System (After units removed or disconnected)—*CAUTION—Fill exactly as follows to prevent air entering the system which will cause pump to be noisy:*

1) With both hydraulic hoses disconnected from the pump, loosen hose connection at the power unit, fill the hoses with fluid and allow it to run out at the power cylinder end until it is free of air bubbles, tighten connections at power cylinder end, connect hoses to pump. *CAUTION*—keep hoses filled with fluid while making the connections.

2) Fill oil pump reservoir to the full mark. Start the engine and run it at idle speed for approximately 10 minutes to remove air which may be trapped in system. *CAUTION—DO NOT TURN STEERING WHEEL DURING THIS PERIOD.*

3) Recheck fluid level, add fluid as required. Install reservoir cover. Check all connections for leaks.

NOTE—If pump is noisy after system has been refilled exactly as noted above, this noise should disappear after several days useage when air in fluid should be dissipated.

BLEEDING HYDRAULIC SYSTEM: Follow steps 2) and 3) of "Refilling System" under LUBRICATION above.

TESTING: If power steering operation is unsatisfactory and cause unknown, refer to "Trouble Shooting" below, and starting with easiest operations first continue to check until trouble found.

Steering Effort: Attach spring scale to spoke near rim of steering wheel. With engine running at idle speed and transmission in neutral, and with front wheels on dry, smooth concrete floor or smooth steel plates, a 3-8 lb. pull should be sufficient to turn wheel one full turn in either direction from center. If steering effort in both directions greater than 8 lbs. at rim of steering wheel, it indicates hard steering. (See "Hard Steering in Both Directions" in Trouble Shooting). If steering effort is more than 8 lbs. in one direction only and very low in other direction refer to "Hard Steering in One Direction Only" in Trouble Shooting for possible causes.

Hydraulic Pressure: If "Trouble Shooting" of items in system other than pump does not disclose trouble, difficulty may lie in pump. To check pump proceed as follows: With engine off, install pressure gauge in pressure line. Turn gauge valve to open position. Start engine and let it idle for approximately two minutes to permit fluid to reach operating temperature. With gauge valve open, turn wheels against a curb or other suitable object and maintain sufficient force on steering wheel to keep hydraulic pressure applied to steering linkage and front wheels. Note pressure shown on gauge, then release steering wheel. (*CAUTION—Do not maintain force on steering wheel for any extended period of time, as this may cause undue wear in hydraulic system*). If pressure reading above is 500-800 psi., the power cylinder and pump are operating properly and it is unnecessary to continue further. If reading less than 500 psi., close gauge valve and note pressure developed by pump, then open gauge valve (*CAUTION—Do not leave gauge valve closed for more than 3 or 4 seconds*). If pressure reading increases to 500-800 psi., pump is delivering sufficient pressure and

CONTINUED ON NEXT PAGE

SAGINAW LINKAGE TYPE (Continued)

fault is in power cylinder (See Power Cylinder Check below). If pressure did not increase to 500-800 psi., replace relief and flow control valve unit and flow control spring. If pressure still low, pump must be removed and overhauled. If pressure ever exceeds 800 psi., replace relief and flow control valve unit

POWER CYLINDER CHECK: Check drag link and stud to make sure it does not bind on valve body Correct if necessary (See Steering Linkage Adjustment above). If drag link is not binding, remove power cylinder piston and rod assembly Check piston and rings and replace if necessary. Make another pressure test and, if pressure still low, replace power cylinder

TROUBLE SHOOTING: *Diagnose trouble as follows:*

Hard Steering in Both Directions—Leak in steering system, pump belt slipping or broken, fluid level low, steering gear and linkage not lubricated, tire pressure low, drag link and stud binding on power cylinder, power cylinder piston rod bent, low pump pressure, loss of pressure in power cylinder, insufficient fluid in system, bind in steering column or gear, improper front end alignment, valve in power cylinder misaligned or sticking

Leaks: At hose fittings, pump body, valve end, around piston rod on power cylinder

Hard Steering in One Direction Only: Tire pressure too low, power cylinder piston rod bent, bind in steering column or gear, improper front end alignment, valve in power cylinder misaligned or sticking.

Car Attempts to Turn Unless Force Applied to Hold Steering Wheel: Tire pressure uneven, drag link and stud binding on power cylinder, valve in power cylinder misaligned or sticking

Poor Recovery on Turns: Tire pressure too low, drag link and stud binding on power cylinder, bind in steering column or gear, bind in power cylinder piston rod, improper front end alignment, valve in power cylinder misaligned or sticking

Noise—Pump belt tension incorrect, fluid level low, pump drive pulley retaining bolt loose, pump drive pulley key does not fit properly, pump shaft bearing worn, bushings worn in pump body or cover, dirt and sludge in pump, drag link stud loose.

REMOVAL & INSTALLATION: Proceed as follows.

Reservoir & Pump Assembly: Removal—Raise hood and drain radiator by opening cock at lower right side of radiator Remove upper radiator hose Disconnect hydraulic hoses at unions on pump (*NOTE*—Secure ends of hoses in raised position at pump unions to prevent oil drainage) Remove drive pulley attaching nut, lockwasher and flat washer (¾" wrench) Loosen two pump-to-bracket screws (9/16" wrench) Slide pump toward engine and remove pulley belt. Remove pump pulley by tapping lightly on back face with a soft hammer Remove two screws attaching pump to bracket (9/16" wrench) Remove reservoir and pump assembly to bench for draining and repair

Installation—Reverse removal procedure Adjust belt tension, then follow procedure outlined for "Refilling System" under LUBRICATION

Valve & Power Cylinder: Removal—Turn front wheels fully to left. Remove cotter pin from drag link ball stud at valve shaft and remove castle nut (7/8" wrench). Remove drag link ball stud from valve shaft with Tool J-2781 Remove cotter pin, end plug, safety plug, spring and ball seat and disconnect valve and cylinder assembly from center steering arm. Raise car and place on stand jacks Disconnect piston rod at support bracket at No. 3 crossmember by removing lock nut and retaining nut (¾" wrench) and push the piston rod through bracket. Remove piston shaft washers, rubber bushings and retaining washers. Disconnect hoses at oil pump and lift valve and power cylinder up through engine compartment (*NOTE*—Use screw caps to plug both hoses and both pump fittings to keep oil from draining out)

Installation—Enter complete assembly through hood opening. Attach piston rod to bracket at No. 3 crossmember, assemble one piston shaft washer, one rubber bushing and one rubber bushing retainer on each side of bracket. Cupped portions of washers should be toward rubber bushings. Install one attaching nut and compress rubber bushing to 1 11/16-1 3/4". Tighten securely. Install second nut and tighten securely. Second nut must be flush with end of shaft. Attach steering arm ball stud housing to center steering arm. Install ball seat on side of center steering arm. Enter steering arm ball, ball seat, dust seal, spring, safety plug and end plug Adjust end plug by tightening plug to end of travel and backing off to nearest cotter pin hole. Install and secure cotter pin Install drag link, nut and cotter pin to valve shaft. Refill system following procedure outlined for "Refilling System" under LUBRICATION

VALVE & POWER CYLINDER OVERHAUL: Disassembly—Clean outside of valve and cylinder assembly thoroughly Remove both hoses from valve body and inspect hoses for wear or cracks Replace if necessary (13/16" and 7/8" fittings) Remove two screws attaching steering arm ball housing and the valve and spool assembly to hydraulic cylinder assembly (*CAUTION—This is a spring loaded assembly and screws should be loosened equally until spring is relieved).* Overhaul components as follows

Hydraulic Cylinder: Hydraulic cylinder serviced only as an assembly Following parts **only** are furnished separately Retaining lock ring, scraper back-up ring scraper, seal back-up ring, piston rod seal

Piston Rod Seal—(*NOTE—Piston seal should not be removed unless there are signs of leakage around the piston shaft seal).* To replace seal, proceed as follows. Use a hook tool or screwdriver and remove retaining lock ring. Remove scraper back-up ring, scraper, seal back-up ring and piston rod seal (*CAUTION—When removing seal do not damage piston rod).* Install NEW oil seal, reversing removal procedure

Valve: Remove valve centering spring Remove "O" ring from pilot lock nut While holding spool shaft nut, remove pilot lock nut (11/16" wrench) Remove control valve assembly with spools from valve shaft Remove valve washer from valve shaft. Remove "O" ring seals from each end of valve body. Remove spools from valve housing, being careful not to damage or drop either the spools or housing (*NOTE*—Check spools and housing bore for excessive wear) Remove pressure and return fittings and seals from valve housing. DO NOT place housing in vise Remove valve washer and valve return spring. Push valve shaft through steering arm ball housing so that valve shaft "O" ring seal may be accessible Remove shaft retaining ring and seal. Remove valve shaft from steering arm ball stud housing. Clean all parts in a clean solvent and blow dry with compressed air

Reassembly: Valve & Power Cylinder—Clamp head of valve shaft in a vise so that shaft is in a vertical position, install steering arm ball housing over valve shaft Install new valve shaft "O" ring and spiral retaining ring. Place valve return spring and valve washer over valve shaft and into steering arm ball housing (*NOTE*—Install valve washers with machined surfaces toward valve spools). Assemble valve spools into valve housing. Insert largest diameter spool in end of housing having three small holes (*CAUTION*—Use care to prevent scratching or nicking spools or bore in housing) Install "O" ring seal in circular housing groove Slide valve housing and spool assembly carefully over valve shaft. The three holes in the valve housing should point up toward threaded end of valve shaft Install valve washer over valve shaft. Apply Lubriplate to valve shaft threads. Install shaft nut until a definite resistance is felt. Back off ½ turn. A minimum of 5/16" thread should be showing beyond nut. (*NOTE*—If there is less than 5/16" thread, the inner valve washer has caught on spool shoulder and is not centralized on valve shaft) After determining that 5/16" dimension is correct, screw on pilot lock nut **by hand.** Using the two valve body-to-cylinder attaching screws and two 3/8"-16 nuts, assemble valve body and shaft together (tighten to 12-15 ft lbs. torque). Tighten valve shaft nut to 9-11 ft lbs torque. Release tension and re-tighten to 3-5 ft lbs torque. While holding valve shaft nut against turning, tighten pilot lock nut to 5-10 ft lbs torque After final tightening, use a fine punch and working through one of the small holes in the pilot lock nut, make a punch mark to stake lock nut to valve shaft Install "O" ring seal on pilot lock nut Remove two cap screws and nuts used to assemble valve body and shaft together Install valve spring Insert housing seal in the contoured ring groove in valve housing Place power cylinder on valve assembly and install attaching screws(dip threads in sealer) (*CAUTION*—Do not gouge or slice pilot lock nut seal when assembling cylinder to valve assembly) Tighten valve housing attaching screws to 12-15 ft lbs torque. Install valve fittings and seals in their proper places Assemble pressure and return hoses to their proper fittings on valve body assembly.

HYDRAULIC PUMP OVERHAUL: *See "Eaton Rotor Type" or "Vickers Van Typ (3-Piece Housing)' under "Power Steering Pumps"*

STEERING GEAR ADJUSTMENT & OVERHAUL: *See "Gemmer Worm & Roller"*

BENDIX LINKAGE TYPE (CHEVROLET TRUCK)

Chevrolet Trucks (1955-59)

DESCRIPTION: Hydraulic power cylinder assembly is mounted on front axle, at one end, and to tie rod at the other. Hydraulic control valve is attached to tie rod between pitman arm and steering arm (replaces pitman arm tie rod). The control valve regulates the flow of fluid under pressure from pump to either anchor end or rod end of cylinder, and the return fluid from either end is directed to fluid reservoir

Hydraulic Pump & Reservoir Assembly: Vane type oil pump is mounted on end frame of generator and driven by a splined extension of the special generator armature shaft. Pump contains a combination overload relief valve which opens at 750-lbs., and a flow control valve which circulates oil within pump as required to regulate output volume.

BELT ADJUSTMENT: Loosen outer bracket-to-generator bolt on generator rear brace, and move generator to obtain correct belt tension. Tighten the retaining bolts. Push in on belt midway between water pump and generator pulleys with light pressure. If tension is correct, there will be 5/16" deflection (6 Cyl.), 13/16" (V8).

LUBRICATION: Checking Fluid Level - Check oil level in reservoir by removing dipstick, and fill to indicated level using Automatic Transmission Fluid Type "A" bearing an "AQ-ATF" number.

Refilling System (After Units Removed or Disconnected): Fill oil reservoir to proper level and let oil remain undisturbed for about two minutes. Raise front end of vehicle so that wheels are off ground. Start engine and run at idle speed for two minutes. Increase engine speed to approximately 1500 RPM. Turn wheels (off ground) right and left, lightly contacting stops. Lower vehicle and turn wheels right and left on ground. Recheck for leaks. Check oil level and refill as required.

Checking Pump Pressure: Disconnect pressure line at pump connection (smallest, top line). *(CAUTION* - Some fluid will leak out when line is disconnected so provision must be made to collect this drainage). Install checking gauge, Tool J-5176, with gauge valve closed on pump and hose connection *(NOTE* - Adapter Kit J-5900 must be used to adapt pressure gauge to pump). Open gauge valve and run engine at idle. Turn wheels (on ground) against stops. Pressure should not be less than 750 lbs (Exc 4000 Series and larger trucks), 600 lbs (4000 Series and larger trucks) If pressure is less, slowly close gauge valve observing pressure increase (pressure will increase as valve is closed if pump is good) *CAUTION - Do not leave valve closed for more than 15 seconds.* If pressure does not increase when valve is closed, pump is faulty Shut engine off and remove gauge and valve and reconnect hose to pump (if pump pressure is satisfactory) Bleed hydraulic system.

Pump Pressure Adjustment: *NOTE - The valve is preset at the factory and should not normally require adjustment* Pump pressure is regulated by the control valve assembly and can be increased or decreased by adding or removing shims located under hex head valve plug. Control Valve Shim, Part No 5682628 (016") should be used in selective combination with shims used in production to set pump pressure Add shims to decrease pressure and remove shims to increase pressure A 016" change is equivalent to approximately 60 lbs change in pump pressure

HYDRAULIC PUMP: Removal - Loosen bracket-to-generator retaining bolts and remove fan belt. Pull generator away from engine. Place a container under the pump and disconnect hydraulic lines from pump allowing oil to drain out of reservoir. Remove retaining bolts from pump-to-generator and generator rear brace on 8 cylinder models and remove pump from vehicle. Drain remaining oil from reservoir.

Disassembly: Remove retaining bolts and sealing washers from pump reservoir-to-pump cover assembly, and remove reservoir. Remove oil filter spring retainer from pump cover assembly. Remove cover plate spring and cover plate and then remove plug and "0" ring, flow spring and pressure relief valve assembly from pump cover. Remove three retaining bolts from pump cover assembly and remove pump cover from pump body. Remove oil filter and retainer. Remove cam ring, pump rotor and vanes. Remove and discard "0" rings from pump body, cover, and cam ring. Remove and discard generator shaft oil seal from pump body.

Inspection: Wash all parts in solvent and dry with a lint free cloth. Check fit of vanes in rotor. Vanes must slide freely, but snugly in slots. Inspect flat face of pressure plate, cam ring, cover, rotor and pump body. If necessary, lap these parts for a good fit. Check surface of pressure relief valve and check fit of valve in pump cover. Correct slight irregularities by polishing.

Reassembly: Coat new "0" rings with Lubriplate and install in pump cover, cam ring and pump body. Install rotor and vanes in pump body with wear pattern or beveled edge of vanes against cam ring inner diameter. Install alignment sleeve in cam ring and install cam ring in pump body *(CAUTION - Wider edge of cam ring should be installed toward pump body. Be certain to align holes in cam ring to body bolt holes. Install rotor with rounded side of splines toward generator end of pump).* Install pressure plate in pump cover and install filter retainer and oil filter. Install cover assembly to pump body, then install plunger and flow control spring. Install plug and "0" ring assembly, cover plate and retainer spring. Install filter retainer spring in cover assembly and install reservoir, retaining bolts and sealing washers.

► *BRASS FITTING NOTE:* Brass fitting seats are of the pressed in type and are replaceable by tapping threads in hole in the seat and then pulling the seat by using a bolt threaded into tapped out seat and a flat washer and nut as an extractor. Install new seats by aligning seat in bore and pressing it into place using the correct hose or tube fitting as a pressing tool.

CONTROL VALVE: Disassembly - Remove three bolts and lockwashers from valve housing and separate drag link from valve housing. Remove ball stud and then remove outer sleeve and flange. Remove Huglock nut and remove inner sleeve with stop screw, and spool bolt as a group. Remove bushing plate. Drive out lock pin, thread stop screw out of inner sleeve, and remove spring seat, spring, and ball stud seats from inner sleeve. Remove spacer from spool bolt and remove spool bolt from stop screw. To remove spool from valve housing, press alternately on the spool end projections by hand sufficiently to expose the "U" cup seals. Remove spool seal bushings and "U" cup seals and spool. Remove control valve plug with a rod having a bent end, and pry against plug. Remove check valve with a screw driver. *NOTE* - The plug and check valve should only be removed to correct a faulty check valve.

Cleaning & Inspection: Wash all parts in solvent and dry then with lint free cloth. Inspect all parts for scratches, burrs, distortion, evidence of wear, and replace all parts where necessary. Replace all seals, gaskets, and covers

Reassembly: Carefully assemble spool into bore of valve housing with the large diameter projection end of spool next to sliding sleeve end. Assemble large bore and small bore "U" cup seals over large and small diameter projections of spool with lips of seals facing each other. Assemble bushing plates on their respective ends of spool. Insert spool bolt through screw stop from side having the large diameter, and assemble spacer on bolt. Assemble lock pin in hole of screw stop and through slot in bolt head to secure bolt to screw stop. Place inner (sliding) sleeve in outer sleeve and flange assembly and then assemble the following parts in sliding sleeve Ball seat, ball stud, ball seat, spring and spring seat. Assemble screw stop with bolt to sleeve assembly by threading screw stop into inner (Sliding) sleeve, and tighten securely. Assemble bushing plate over bolt and on shoulder of outer sleeve flange. Insert spool bolt through hole in spool and assemble Huglock nut and secure as follows draw up nut tight then back off nut (less than ¼ turn) until the spool can be rotated with a minimum of endplay. Position drag link flange on valve housing so ball stud is on side opposite the valve ports. Align holes and assemble three bolts and lockwashers and tighten to 40-45 ft lbs

POWER CYLINDER: Disassembly - *(NOTE - This only repair to make in the field on the power cylinder is the replacement of piston rod seals).* Before removing piston rod seal parts from rod bearing end of power cylinder, clean the exposed portion of seal cavity with clean solvent, brush and compressed air. Remove snap ring. To dislodge scraper, washer, dust seal, seal back-up washer and "U" cup seal, use air hose and apply pressure to cylinder port (right hand port, looking down), and seal the left hand port. Remove seal parts from rod.

Cleaning and Inspection: Clean all parts in solvent and dry with compressed air. *(CAUTION* - Do not use waste to wipe off spool or inside bore of valve housing). Protect spool edges and bore of valve housing from damage during disassembly and reassembly. Inspect parts for nicks and burrs and excessive wear. Check cylinder scraper washer for fit on piston rod, which should be .001-.0035". Replace if worn.

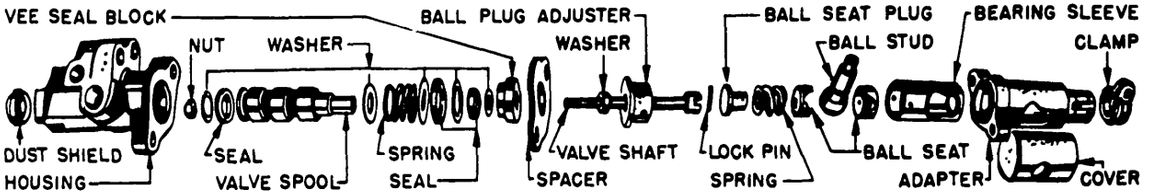
Reassembly: Assemble open side of "U" cup seal over the rod and into bearing cavity, seal back-up washer, dust seal (with side away from seal cavity), and scraper washer. Slide parts in place on rod and lock in place with snap ring.

POWER STEERING PUMP: Same as used on passenger cars. *See "1955-59 Chevrolet Power Steering Pump".*

1955-59 CHEVROLET (PASS. CAR) LINKAGE TYPE

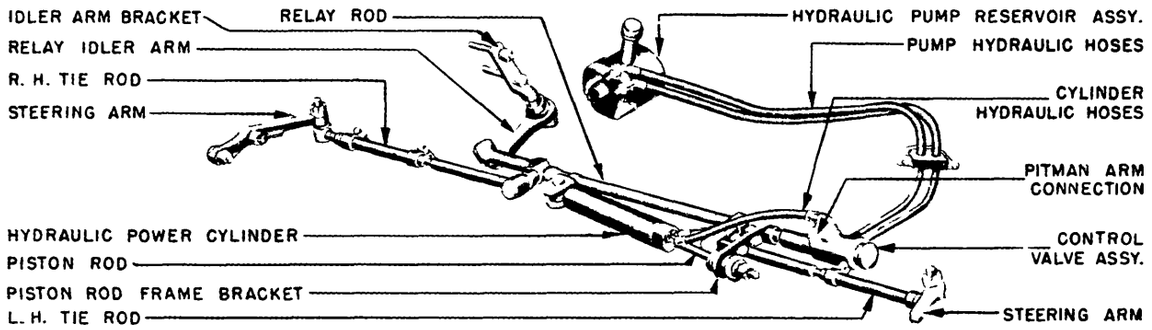
Ch vrol t Pass. Cars (1955-59)

DESCRIPTION: Hydraulic linkage type. Hydraulic power cylinder assembly is mounted on a bracket on the relay rod at one end and to bracket on frame at other end. Hydraulic control valve is attached to left end of steering relay rod and is operated by pitman arm acting on spool valve assembly, through valve shaft. Spool is restricted to a .050" travel to right and left from centered position. Spool valve is normally centered (straight -ahead position) and in this position oil from hydraulic pump flows through center passage of valve body, through annular grooves in spool to annular passages in housing and back to pump. When axial movement of spool occurs with a 3 lb. effort on steering wheel, direct circuit of pump is interrupted by shutting off both direct return passages. Oil is then forced to travel to one end of power cylinder to move cylinder axially on piston shaft. At same time opposite end of power cylinder is open to hydraulic pump return line and permits oil at this end to return through control valve to pump reservoir. Manual steering is possible when hydraulic power not available.



BELT ADJUSTMENT: Loosen outer bracket-to-generator bolt and retaining bolt on generator rear brace. Pull generator out from engine with all slack taken out of belt. Tighten retaining bolts. Push in on belt midway between water pump and generator pulleys with light push. If tension correct there will be 5/16" (6 Cyl.), 13/16" (8 Cyl.), deflection at this point with light push.

LUBRICATION: Checking Fluid Level–Check oil level in reservoir by removing dipstick. Fill to indicated level using Automatic Transmission Fluid "Type A" bearing an "AQ-ATF" number.



R filling System (Aft r Units Removed or Disconnected): Fill oil reservoir to proper level and let oil remain undisturbed for about two minutes. Raise front end of vehicle so that wheels are off ground. Start engine and run at idle for two minutes. Increase engine speed to approximately 1500 RPM. Turn wheels (off ground) right and left, lightly contacting stops. Lower car and turn wheels right and left on ground. Recheck for leaks. Check oil level and refill as required.

CONTROL VALVE: (R m val)–Raise front of car and place it on stands. Loosen relay rod to control valve clamp and disconnect the two pump to control valve hose connections. Drain fluid into a container and then disconnect the two remaining valve to power cylinder hoses. Remove the retaining nut from the ball stud to pitman arm connection and disconnect control valve from pitman arm. Turn pitman arm to right to clear control valve and unscrew control valve from relay rod. Remove control valve.

Disass mbly: Remove dust shield from control valve housing and remove retaining pin and nut from valve shaft. Remove retaining bolts connecting valve assembly housing to adapter assembly housing and separate the two assemblies. *(NOTE–*Valve spool remains in housing when the two assemblies are separated. The seal at the end of the spool makes it necessary that spool be removed from the end of the housing). Remove spring thrust washer, spring, flat washer, "V" seal assembly, flat washer and spacer from valve shaft. Remove ball stud cover from adapter assembly housing. Push ball stud to the end of the adapter housing and remove lockpin. Remove threaded ball plug adjuster and valve shaft. Remove ball seat plug, spring, ball seats and ball stud. Remove bearing sleeve.

POWER STEERING CONTROL VALVE ASSEMBLY

CHEVROLET POWER STEERING ASSEMBLY

Inspection: Wash all parts in solvent and dry with a lint free cloth. Inspect all parts for scratches, burrs, distortion, evidence of wear, and replace all parts that are worn or damaged, including mating parts where necessary. Replace all seals, gaskets and covers.

Reassembly: Place ball seat in bearing sleeve and insert sleeve in housing. Insert ball stud in sleeve. Install the remaining ball seat, spring and spring seat in bearing sleeve *(CAUTION–This is the heavier of the two springs used in the control valve).* Install valve shaft in adjuster and screw adjuster into sleeve. Tighten adjuster until it bottoms, and then back if off ¼ turn, plus or minus the amount necessary to install lockpin in nearest hole *(CAUTION–*Be sure ball seats remain in correct position, otherwise there will be insufficient clearance to correctly install retaining pin). Install ball stud cover and install washer and annulus spacer on the valve shaft. Install "V" seal block and ring assembly. Install the annulus washer, spring and spring thrust washer with chamfered side of thrust washer toward spool side. Install spool valve assembly and retaining nut *(CAUTION–*Install spool valve with the "V" seal at the threaded end of valve shaft). Tighten the retaining nut to 25 inch lbs. with a torque wrench and install retaining clip. Make sure that all parts are correctly located before tightening. Insert the assembled valve and adapter assembly into valve housing and install retaining bolts and lockwashers. Fill the end area with GM 4617-M grease and install valve housing dust cover.

Installation: Install control valve on relay rod so that distance from center of control valve ball stud to center of tie rod end ball stud measures approximately 3 5/8". Tighten control valve clamp *(NOTE–*The clamp securing control valve to relay rod end should be positioned before tightening so that it will not interfere with steering linkage. Reconnect the four hydraulic hoses to control valve and fill system with Automatic Transmission Fluid Type "A".

POWER CYLINDER: (Removal)–Disconnect hydraulic lines connected to cylinder and drain fluid into a container. Remove retaining nut, washer, and rubber grommet from cylinder rod to brace attached to frame. Remove cotter pin, retaining nut, flat washer and bolt from end of power cylinder where it is fastened to relay rod bracket. Remove power cylinder.

Inspection: Inspect seals for leaks around cylinder rod and if leaks are present, replace the seals as follows: Use a hook tool and remove retaining ring. Remove wiper ring, backup washer, backup seal ring and seal *(NOTE–*Piston rod should not be removed unless there are signs of leakage along piston shaft at the shaft seal). Examine brass fitted hose connection seats for cracks or damage and replace if necessary. If other service required on power cylinder, replace the unit.

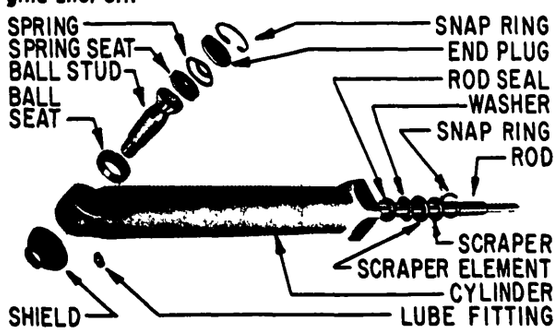
Installation: Install power cylinder by reversing the reversing the removal procedure. Reconnect the hydraulic lines and fill system with Automatic Transmission Fluid Type "A".

POWER STEERING PUMP: S *"1955-59 Ch vrol t Pow r Steering Pump".*

1960 CHEVROLET PASS. CAR LINKAGE TYPE

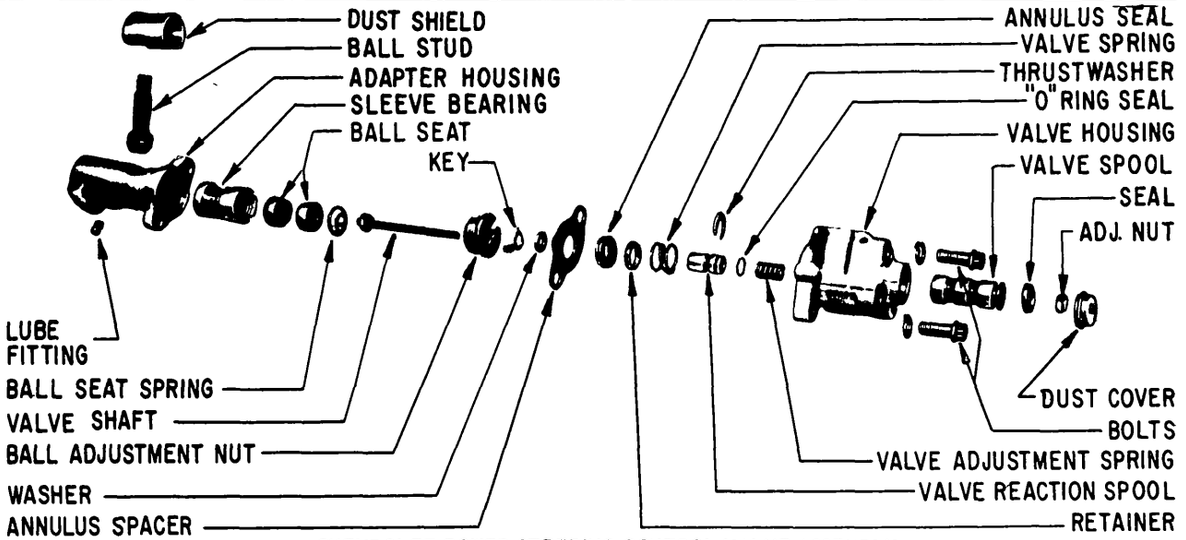
Chevrolet Pass. Cars (1960)

►CHANGES, CAUTIONS, CORRECTIONS



►*1960 (EARLY CARS) POWER STEERING RESERVOIR OVERFLOWING NOTE: On early models, the power steering reservoir will overflow when wheels are turned from right to left with engine stopped.*

DESCRIPTION: Linkage type with power cylinder mounted between steering relay rod and bracket on frame side rail. Control valve assembly is mounted on left side relay rod and is operated by pitman arm acting on spool valve assembly. The new control valve assembly is adjustable to provide greater uniformity of operation and faster response. The new power steering pump is mounted on engine and is driven by a belt from crankshaft pulley.



ADJUSTMENT: Power Steering Pump Belt - Loosen power steering pump-to-bracket attaching bolts and move pump, with belt in place, until belt is tensioned so that a 15 lbs. force applied at midpoint between fan pulley and pump pulley will cause a ½" to ¾" belt deflection, then tighten mounting bolts.

Control Valve Balancing: *NOTE - If a hard steering effort is required (in one direction), balance control valve as follows:* With car on a hoist, engine running, and power cylinder rod disconnected from frame bracket, piston rod will be fully retracted or fully extended (if valve is out of balance). If piston rod remains retracted, turn adjusting nut clockwise until rod begins to move out, then turn nut counterclockwise until rod begins to move in. Now turn nut clockwise to exactly one-half the rotation needed to change direction of shaft movement. If rod remains extended, move nut counterclockwise until rod begins to retract, then clockwise until rod begins to move out. Now position nut to exactly one-half the rotation needed to change direction of shaft movement. *CAUTION - Do not turn nut back and forth more than is absolutely necessary to balance valve.* With valve properly balanced, it should be possible to move rod in and out manually. Stop engine and connect cylinder rod to frame bracket, then restart engine. If front wheels (still on hoist) do not turn in either direction from center the valve is properly balanced. With valve properly adjusted, install dust cap.

LUBRICATION: *NOTE - On early cars, check fluid level in reservoir with oil at normal operating temperature and front wheels in straight ahead position, with engine shut off.*

POWER CYLINDER ASSEMBLY

CHEVROLET POWER STEERING CONTROL VALVE ASSEMBLY

Checking Fluid Level: Check oil level in reservoir by removing dipstick (normal operating temperature). Fill to indicated level with Automatic Transmission Fluid.

Bleeding Hydraulic System: Fill reservoir to proper level and let oil remain undisturbed for at least two minutes, then start engine and run at idle speed for two minutes. Add oil if necessary, raise front of car so wheels are off ground. Increase engine speed to 1000 RPM and turn wheels full right and left, contacting stops lightly. Lower car and turn wheels right and left on the ground. Check oil level and refill as necessary. Continue this process as long as required to bleed all air from system (oil in reservoir should be clear).

REMOVAL & INSTALLATION

CONTROL VALVE: Removal - Raise front of car and place it on stands, then loosen relay rod to control valve clamp and disconnect the two pump to control valve hose connections. Drain fluid into a container and then disconnect the two remaining valve to power cylinder hoses. Remove retaining nut from ball stud to pitman arm connection and disconnect control valve from pitman arm. Turn pitman arm to right to clear control valve and unscrew control valve from relay rod.

Installation: Install control valve on relay rod so that distance from center of control valve ball stud to center of tie rod end ball stud measures approximately 3 5/8", then tighten control valve clamp. *NOTE - Clamp securing control valve to relay rod end should be positioned before tightening so that it will not interfere with steering linkage.* Reconnect the four hydraulic hoses to control valve and fill system with Automatic Transmission Fluid Type "A". Balance control valve *(see "Control Valve Balancing" above).*

POWER CYLINDER: Removal - Disconnect hydraulic lines connected to cylinder and drain fluid into a container. Remove retainer nut, washer, and rubber grommet from cylinder rod to brace attached to frame. Remove cotter pin, retaining nut, flat washer and bolt from end of power cylinder where it is fastened to relay rod bracket. Remove power cylinder.

Installation: Install power cylinder by reversing removal procedures. Reconnect lines and fill system with Automatic Transmission Fluid Type "A". Bleed air from system (see above).

POWER STEERING PUMP: Removal - Disconnect hoses from pump and secure ends in a raised position, then cap all open fittings. Loosen pump bracket-to-pump bolts and remove pump from car. Remove drive pulley attaching nut and slide pulley from shaft. *CAUTION - Do not hammer pulley off shaft.*

Installation: Slide pulley on shaft (do not hammer on shaft), then install pulley nut and tighten to 35-45 ft. lbs. *NOTE - Always use a new pulley nut.* Position pump assembly on mounting bracket and install bolts loosely, then connect and tighten hoses. Fill reservoir with Automatic Transmission Fluid Type "A" and bleed pump by turning pulley (counterclockwise as viewed from front) until air bubbles cease to appear. Move pump outward until belt is properly tensioned (see "Belt Adjustment" above), then tighten mounting bolts.

OVERHAUL

CONTROL VALVE: Disassembly - Place valve assembly in a vise with dust cap upward. *CAUTION - Clamp adapter housing end of assembly only in vise.* Remove dust cap, then remove adjusting nut. Remove valve to adapter bolts and remove valve housing and spool from adapter. Remove spool from housing, then remove spring, reaction spool, washer, reaction spring, spring retainer, and seal. Remove "O" ring from reaction spool. Remove annulus spacer, valve shaft, washer and plug to sleeve key. Turn adjusting plug out of sleeve very carefully so as not to nick top surface. Remove adapter from vise and invert, permitting one of the two ball seats to drop out. Remove ball stud and the other ball seat and the seal will drop out.

Inspection: Wash all metal parts in solvent and dry with a lint free cloth. Inspect all parts for scratches, burrs, distortion or wear. Replace all seals, gaskets, covers.

Reassembly: Install sleeve and ball seat in adapter, then install ball stud, other ball seat and spring (small coil of spring down). Clamp adapter in vise, then put shaft through seat in adjuster plug and screw adjuster plug in sleeve. Turn plug in until it is tight, then back it

CONTINUED ON NEXT PAGE

1960 CHEVROLET LINKAGE TYPE (Cont.)

off until slot lines up with notches in sleeve. Insert key, making sure that small tangs on ends of key fit into notches in sleeve. Install valve shaft washer, annulus spacer, and reaction seal (lip up), spring retainer, reaction spring and spool, washer and adjustment spring. *NOTE - Install "O" ring on reaction spool before installing spool on shaft.* Install washer with chamfer up. Install seal on valve spool (lip down), then install spool in housing being careful that spool is not jammed in housing. Install housing and spool onto adapter with side ports on same side as ball stud, then bolt housing to adapter. Depress valve spool and turn lock nut onto shaft about four turns. *NOTE - Always use a new locknut.* Install valve in car and balance before installing dust cap.

POWER CYLINDER: Disassembly - To remove piston rod seal, remove snap ring, then pull out on rod, being careful not to spray oil out of parts. Remove piston rod scraper and scraper element, back-up washer and piston rod seal from rod. To remove ball stud, depress end plug and remove snap ring. Push on end of ball stud and the end plug, spring, spring seat and ball stud may be removed. If ball seat is to be removed it must be pressed out using a suitable size socket.

Reassembly: Reverse disassembly procedures and note the following: Apply a thin coating of Lubriplate on inner surfaces of seal and scraper element before reassembly. Fill area beneath end plug with GM grease, Part No. 4618-M. Make sure snap rings are firmly seated in grooves.

POWER STEERING PUMP: *See "Chevrolet Power Steering Pump".*

PRESSURE TEST: Disconnect pressure line at pump connection and install checking gauge, Tool J-5176 (with gauge valve closed) on pump and hose connection. *NOTE - Adapter Kit J-5900 must be used to install pressure gauge to pump.* Open gauge valve and run engine at idle speed, then turn wheels (on ground) against stops. Pressure should not be less than 750 lbs. If pressure is less, slowly close valve and check for pressure increase. *NOTE - Pressure will increase if pump is in good condition.* If pressure does not increase with valve closed, pump is faulty. *CAUTION - Do not hold valve closed more than 15 seconds.* After removing gauge, bleed hydraulic system (see above).

FORD TRUCK LINKAGE TYPE POWER STEERING

Ford Truck, Exc. Tilt Cab Models (1958-60) ℂ
Ford Truck Tilt Cab Models (1958-60) ℂ

ℂ - Power cylinder used.
ℂ - Booster (rack & piston) cylinder used.

▷CHANGES & CORRECTIONS

▷*1959 F-600 TRUCK FRONT END SHIMMY CORRECTION (POWER STEERING MODELS):* This condition may be caused by collapsed power steering piston rod insulators. To correct, install new type insulators, Part No. B9T-3314-A.

DESCRIPTION: Linkage type with control valve assembly connected directly to steering gear pitman arm. On Tilt Cab Models, the operating cylinder is a "rack & piston" booster type cylinder connected between pitman arm and wheel spindle. On other models, the hydraulic power cylinder is anchored to left side of front axle with the piston rod connected to center of spindle connecting rod. The only basic differences between the two units is in the construction of the operating cylinders.

ADJUSTMENT: Pump Drive Belt - ½" belt deflection midway between pulleys. Tighten belt adjusting bolt to 30-35 ft. lbs.

LUBRICATION: Check fluid level every 1000 miles. Remove cover from reservoir and add Automatic Transmission Fluid as required to bring level within 1 inch of top of reservoir.

TESTING: Turning Effort - With front wheels properly aligned and tire pressure correct, place car on dry concrete, set brakes, then proceed as follows: With engine at normal idle speed, turn wheel to right and left several times to bring fluid to normal operating temperature. Hook a spring scale to rim of steering wheel and measure pull required to wheel at least one complete turn in both directions. The pull should be 35-65 lbs., and about equal in both directions.

Pump Pressure: Install pressure gauge, Tool T54L-33610-C between pump hose and pump outlet with pressure gauge between pump and shutoff valve of tool. Run engine at idle speed (with shutoff valve open) for two minutes to normalize oil temperature. Note pressure reading while turning wheels to full right and left positions. Pressure should be 50-60 lbs. (F-100); 60-70 lbs. (F-200 to F-600). Increase engine speed to 2500 RPM, then slowly close shutoff valve. Pressure should increase to 900-1050 lbs. *CAUTION - Do not leave valve closed for more than 15 seconds.* If pressure is less than minimum, pump is faulty. If pressure increases but does not reach maximum, inspect pump, control valve, and power cylinder. If pressure is within limits and power steering is not satisfactory, trouble is in control valve or power cylinder.

TROUBLE SHOOTING: Binding or Poor Recovery - Check pitman arm ball stud in drag link outer sleeve. Check steering gear adjustments. Check operation of control valve spool in valve housing. Check for interference between sector shaft arm and dust shield. Check valve spool bolt locknut adjustment. Check control valve inner and outer sleeves for damage.

Hard Steering: Check hydraulic pressures. Check control valve and control valve spool. Check sector arm ball stud for free movement.

Excessive Free Play: Check steering gear worm and roller mesh adjustment. Check clearance between sector arm ball stud and ball stud seats.

Noise: Check and adjust pump belt tension. Check to make sure correct hose is being used. If necessary, remove and check pump. Bleed air from system by turning wheel several times to each stop.

Steering Chatter: Loose pump belt. Check for looseness in spindle connecting rod connections.

Rattles: Check for looseness between sector arm ball stud and seats.

Loss of Power Assist: Check system for damage or broken hoses. Check hydraulic pressures. Check control valve and power cylinder.

POWER STEERING PUMP: Removal - Remove reservoir cover, then disconnect reservoir-to-pump hose from pump and drain fluid from reservoir. Disconnect pump-to-control valve hose from pump, and fasten it in a raised position to prevent fluid from draining out. Remove belt, then remove pump.

Installation: Reverse removal procedure and adjust pump belt to specifications.

CONTROL VALVE: Removal - Disconnect four hose assemblies at control valve fittings and drain fluid from hoses. Remove dust cover from end of drag link outer sleeve, then remove cotter pin and unscrew drag link ball plug from end of sleeve. Remove nut and bolt from drag link dust shield (if so equipped). Turn steering wheel so steering sector shaft moves toward rear of truck and remove washer and outer drag link ball seat from sleeve. Pull sleeve away from sector shaft arm ball stud. Remove dust shield from sector shaft arm stud. Remove inner drag link ball seats and spring from the sleeve, then disconnect forward end of drag link from left spindle arm and remove control valve and drag link assembly from truck.

Installation: Install a new dust shield on steering sector shaft arm if old shield is worn or damaged, then install drag link stud in spindle arm and tighten nut to 45-55 ft. lbs. (F-100, F-250); 60-70 ft. lbs. (F & P-350, P-400 F-500 & 600, B-500 & 600, P-500), 90-100 ft. lbs. (C-550 & 600), and install new cotter pin. Position flat faced inner ball seat, ball spring, and the other inner ball seat in control valve sleeve. Install control valve sleeve on sector shaft arm ball, then install outer ball seat and washer in end of sleeve. Install the plug. Tighten control valve sleeve plug until ball spring is fully compressed, then back plug off to first cotter pin hole and install a new cotter pin. Connect four hose assemblies at control valve and drag link fittings with chassis lubricant, then fill reservoir to correct level with Automatic Transmission Fluid. Operate engine at idle speed for about two minutes, check fluid level, then check all hose connections for leakage. Increase engine speed to 1000 RPM, then turn steering wheel to right and left several times. Stop engine and check control valve and hose connections for leakage. Recheck fluid level in reservoir.

POWER CYLINDER (EXCEPT TILT CAB TRUCKS): Removal - Disconnect control valve-to-power cylinder hoses at power cylinder and fasten ends of hoses in a raised position to prevent fluid drainage. Disconnect spindle connecting rod at end of power cylinder, then disconnect power cylinder from truck.

Installation: Position anchored end of power cylinder in its mounting bracket with a bushing on either side, then install anchor pin through bottom of the bracket and tighten nut securely. Place a washer and insulator on piston rod, then insert end of rod through stud eye or mounting bracket on spindle connecting rod. Place

CONTINUED ON NEXT PAGE

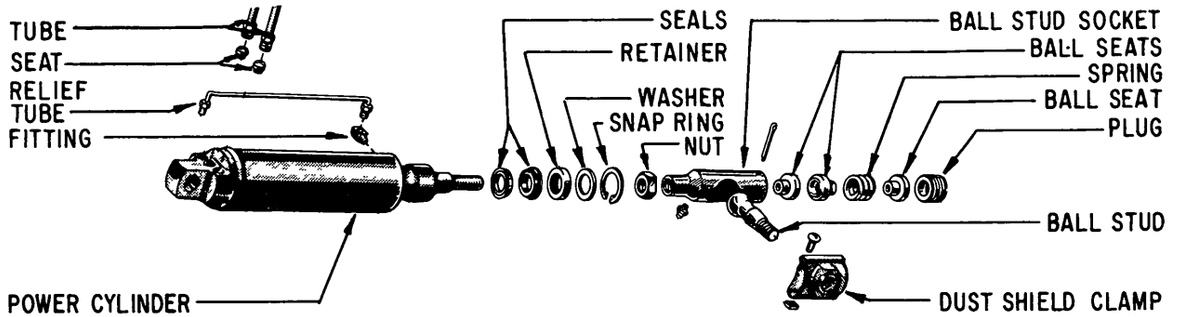
FORD TRUCK LINKAGE TYPE POWER STEERING (C nt.)

an insulator, washer, and nut on end of rod, and tighten nut until washer bottoms on piston rod shoulder. Install locknut. Connect hoses to control valve and tighten fittings securely. Fill reservoir to specifications with Automatic Transmission Fluid, then start engine and run at idle speed for two minutes and check for fluid leakage. Bleed air from system by turning wheel fully to right and left.

BOOSTER CYLINDER (TILT CAB MODELS): Removal - Tilt cab forward and drain cooling system, then remove fan assembly. Disconnect upper and lower radiator hoses and the accelerator and choke cable clamps, then remove radiator assembly. Remove intermediate sector shaft arm (pitman arm) from booster cylinder sector shaft. Place a drain pan under cylinder, then disconnect left turn and right turn lines from cylinder. Remove booster cylinder-to-frame retaining bolts and cylinder.

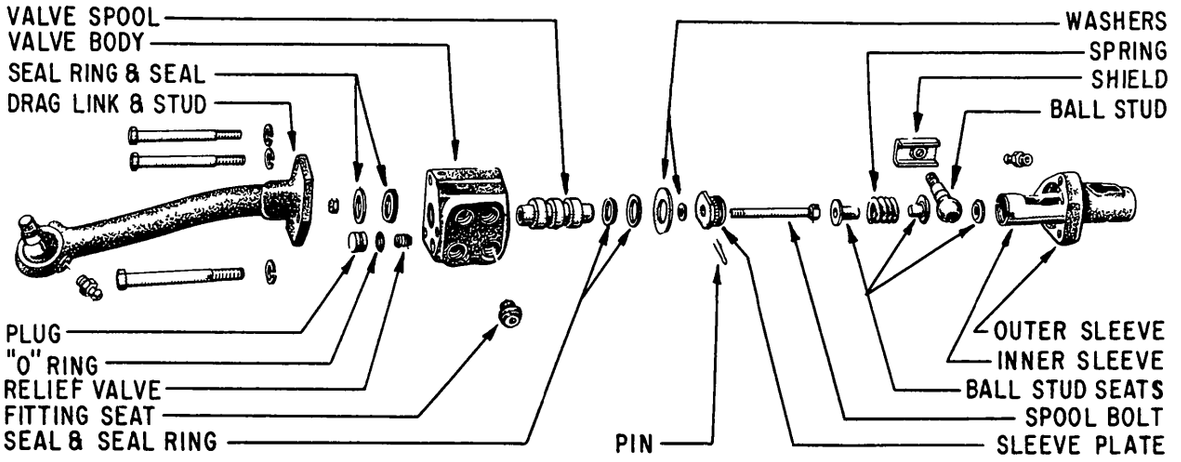
Installation: Position booster cylinder on frame and install retaining bolts. Connect right and left turn lines to cylinder and tighten fittings to 30-40 ft. lbs. Install intermediate sector shaft arm on sector shaft and and tighten nut to 180-220 ft. lbs. Complete installation by reversing removal procedure. Fill cooling system, then fill power steering reservoir with Automatic Transmission Fluid. Operate engine and check for leakage, then bleed system of air by turning wheel fully to right and left.

OVERHAUL



CONTROL VALVE: Disassembly - Drain as much fluid as possible from hose fitting holes on top of control valve housing, then clean outside of housing, being careful not to allow dirt to enter holes. Remove four bolts that fasten drag link control valve housing and drag link outer sleeve together, then separate drag link and outer sleeve from housing. Remove locknut from end of control valve spool bolt, and remove bolt, washer, and inner sleeve from housing. Remove control valve spool and housing seals from housing. *NOTE - One of the seals can be pushed out with the spool, and the other seal can be removed from opposite end of housing.*

moved from opposite end of housing.



Inspection: Inspect all parts for wear or damage. Examine lips of seals carefully for nicks or scratches that would allow fluid to escape from control valve. Inspect spool for nicks or burrs and scoring. Remove burrs with crocus cloth. DO NOT round off sharp edges on spool. Inspect housing for burrs, and scored or damaged surfaces. Remove burrs with crocus cloth. With spool clean and dry, insert spool in housing. Spool should fall free of its own weight. Check fit of drag link inner and outer sleeves. Inner sleeve should slide freely in outer sleeve. Check ball stud seats for wear or damage.

Check Valve Replacement: If necessary to replace return port relief check valve assembly in control valve housing, remove plug from forward end of housing. *NOTE - Apply air pressur to return port to blow plug out.* Remove relief valve with a screwdriver, then install a new valve. Install plug in relief valve hole.

Valve Housing S at R plac m nt: If necessary to replace control valve hose connector seats, tap the existing hole in hose seat, using a 3/8" starting tap for the large hose seat and a ¼" starting tap for small seats. *CAUTION - Remove all metal chips from hose seat port after tapping.* Place a nut and large flat washer on a bolt of the same size as tapped hole (washer large enough to cover hose seat port). Thread bolt into tapped hole and turn nut to remove hose seat. Place a new hose seat in port and thread a bolt of the same size as port into the port. Tighten bolt enough to bottom seat in port.

FORD TRUCK POWER STEERING POWER CYLINDER

FORD TRUCK POWER STEERING CONTROL VALVE ASSEMBLY

Reassembly: Lubricate all parts with Automatic Transmission fluid, then insert valve spool in housing with large end of spool toward inner sleeve end of housing. Rotate spool while inserting it. Install two seals in control valve housing over ends of the spool (beveled lip of each seal should be against outer edge of valve housing bore). *CAUTION - Do not nick or scratch seal during installation.* Position valve spool bolt in drag link inner sleeve, then place washer over forward end of inner sleeve and position inner sleeve on end of control valve housing. Install a new locknut on end of valve spool bolt, and tighten nut securely. Back off the nut 1/16-1/8 turn until spool bolt can be rotated freely (without endplay) while holding the spool. Place drag link, control valve housing, and drag link outer sleeve together in their correct positions, then install and tighten the four bolts fastening the three parts together. Install new lock wires on bolts.

POWER CYLINDER (EXCEPT TILT CAB MODELS): *NOTE - Power cylinder internal parts and rod, except seals and hose seats, cannot be replaced.*

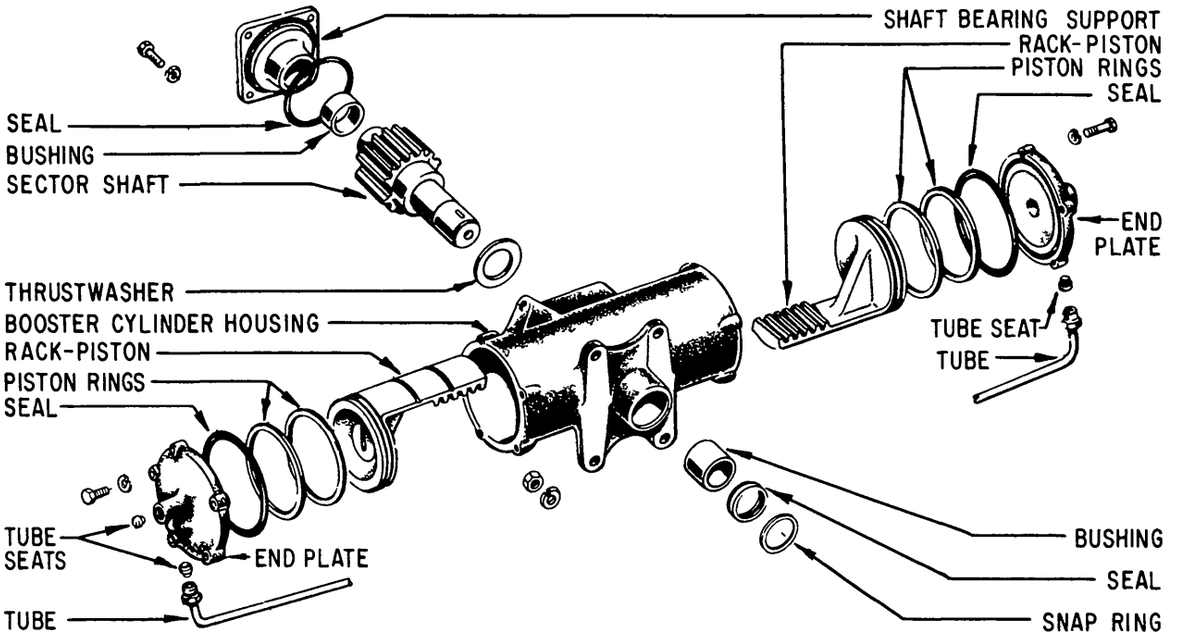
Seal Replacement: Clamp power cylinder in a vise and remove snap ring from end of cylinder. *CAUTION - Be careful not to distort or crack cylinder.* Pull piston rod out all the way to remove scraper, bushing, and seals. Lubricate new inner seal with Automatic Transmission Fluid and place seal, bushing, outer seal, and scraper on piston rod. Push rod in all the way, then install parts in cylinder with a deep socket slightly smaller than cylinder opening. Install snap ring in end of cylinder.

Hose Seat Replacement: Procedure is the same as installing seats in control valve. *See "Control Valve" above.*

POWER CYLINDER (TILT CAB MODELS): Disassembly - Remove front end plate-to-rear end plate connector tube and drain as much fluid as possible from cylinder. Remove sector shaft bushing support plate from side of cylinder, then remove sector shaft and thrust washer from housing. Remove both of the cylinder assembly

CONTINUED ON NEXT PAGE

FORD TRUCK LINKAGE TYPE POWER STEERING (C nt.)



end plates, then reach in through support plate opening and push piston out of cylinder Remove sector shaft seal snap ring, and remove seal

Insp cti n: Clean all parts with solvent and wipe dry with a clean lint free cloth Blow out all passages and grooves Inspect cylinder bore for nicks, scores, and scratches Touch up minor damages with crocus cloth *NOTE - Cylinder housing is not available as a service part If replacement is necessary, the complete unit must b replaced* Inspect piston rings for scores on contact surfaces and replace rings if necessary Check ring side clearance which should be 002- 004" Check condition and clearance of sector shaft bushing Clearance should be 0005- 0025" Check sector shaft for burred or broken teeth and for rough spots on bushing and seal contact surfaces Inspect end plates, bushing support plate, and cylinder housing for nicks and burrs on mating surfaces Dress any rough spots with a file Inspect tube connector seats in housing and end plates and replace seats if necessary Check thickness of sector shaft thrust washer which should be 058- 062" thick If less than minimum, replace thrust washer

Conn ctor S at Replacement: Procedure is the same as installing seats in control valve *See "Control Valve" above*

Bushing R plac m nt· If clearance between sector shaft and bushings exceeds 0025", or if bushings are damaged, replace as follows Press bushing out of housing or support plate with a suitable tool When pressing bushing into housing or support plate, place slit in bushing at bottom center or top center Press bushing into housing far enough so that thrust washer will not ride on it, and will be approximately flush with seal counterbore Press bushing into support plate flush with, or a little below, edge of its bore

R assembly: Lubricate sector shaft seal with Automatic Transmission Fluid and position it in shaft bore in cylinder with metal side of seal facing outward Install seal snap ring Lubricate pistons, rings and cylinder bore with Automatic Transmission Fluid, then compress rings with a piston ring compressor tool (stagger the ring gaps), and install piston in cylinder by tapping

FORD TRUCK POWER STEERING BOOSTER CYLINDER

gently with a hammer handle Position rack of front piston at the top of cylinder and rear piston at bottom of cylinder The two center teeth on each rack are identified by "X" marks The upper and lower center teeth on sector shaft pinion are also identified by "X" marks Position the pistons in cylinder so "X" marks on pinion teeth are located between "X" marks on racks when sector shaft is installed Place sector shaft thrust washer in cylinder housing, then install sector shaft with serrations facing down and with "X" marks properly aligned Install a new "O" ring seal in groove in sector shaft bushing support plate, then install support plate

NOTE - Mounting holes are not concentric, and support plate can be installed only in one position Tighten screws to 12-15 ft lbs Install a new "O" ring seal in groove in front end plate (end plate with two tube connector holes) Install front end plate making sure to position end plate connector tube hole facing down and slightly toward frame mounting bracket Tighten screws to 12-15 ft lbs Install a new "O" ring seal in rear end plate groove, then install rear end plate on cylinder, making sure the tube connector hole is lined up with its counterpart in front end plate Tighten screws to 12-15 ft lbs Install front end plate to rear end plate connector tube and tighten fittings to 30-40 ft lbs

HYDRAULIC PUMP: *See "Eaton Roller Type Pow r Steering Pump"*

GEMMER HYDRAGUIDE (CHRYSLER & DESOTO) (INTERNAL OIL PASSAGE TYPE)

Chrysler (1954)
DeSoto (1954)

►CHANGES & CORRECTIONS

►*1954 "HIGH SPOT" OR "LUMPY FEELING" AT OR NEAR STRAIGHT AHEAD POSITION (Or feeling of oversteering when turning from center to right or left)* Check and adjust Cross-shaft Backlash and check Steering Tube-and-Column Alignment EXACTLY as detailed below NOTE—See 1953 Steering Column Jacket Bearing Spring Change (below)

DESCRIPTION

DESCRIPTION: The "Internal Oil Passage" Power Steering Gear is of the same basic design and operates on the same principle as the previous Gemmer Hydraguide type. The new type has numerous structural changes

Gear Housing—Cast aluminum (was malleable iron) Oil passages are provided in the housing and all external oil tubing and connections have been eliminated.

Power Cylinders—Cylinders are gray iron castings with integral mounting flange and are attached by capscrews No piston travel adjustment is required

Valve Body & Valve Body Cap—Both parts are die-cast aluminum Valve identification is stamped on valve body above each valve cylinder.

Power Piston Assembly—Two piece aluminum die-cast type with new seal ring assemblies (rectangular section rubber seal ring backed up by molded nylon ring) *NOTE*—Piston assembly is interchangeable with previous type used in earlier model steering gears

Worm Adjustment—Threaded type adjustment screw and locknut provided in worm shaft lower cover (replaces adjusting shims).

Worm Lubrication—Entire steering gear (including worm and roller now lubricated by SAE 10-W Engine Oil (used for both lubrication and hydraulic power). Nylon Elastic Stop Nuts and nylon washers are used on both the worm and shaft adjusting screws for sealing at these points.

Hydraulic Pump & Reservoir Assembly: "Single Rotor" type mounted on generator and driven by armature shaft *See Hydraulic pump data in "Gemmer Hydraguide (External Oil Passage Type)".*

LUBRICATION: *CAUTION—New "Internal Oil Passage" type is lubricated entirely by the hydraulic pressure oil supply and special lubricant not required for steering gear worm-and-roller (as on previous External Oil Tube type).*

Checking Fluid Level: Check at 1000 mile intervals or every 30 days. Thoroughly clean top of reservoir, remove cover. Add oil as required to maintain level even with mark stamped on inside of reservoir or ½" above top of filter element.

Recommended Oil—SAE. 10W (MM or MS). For temperatures below —10°F., use SAE. 5W.

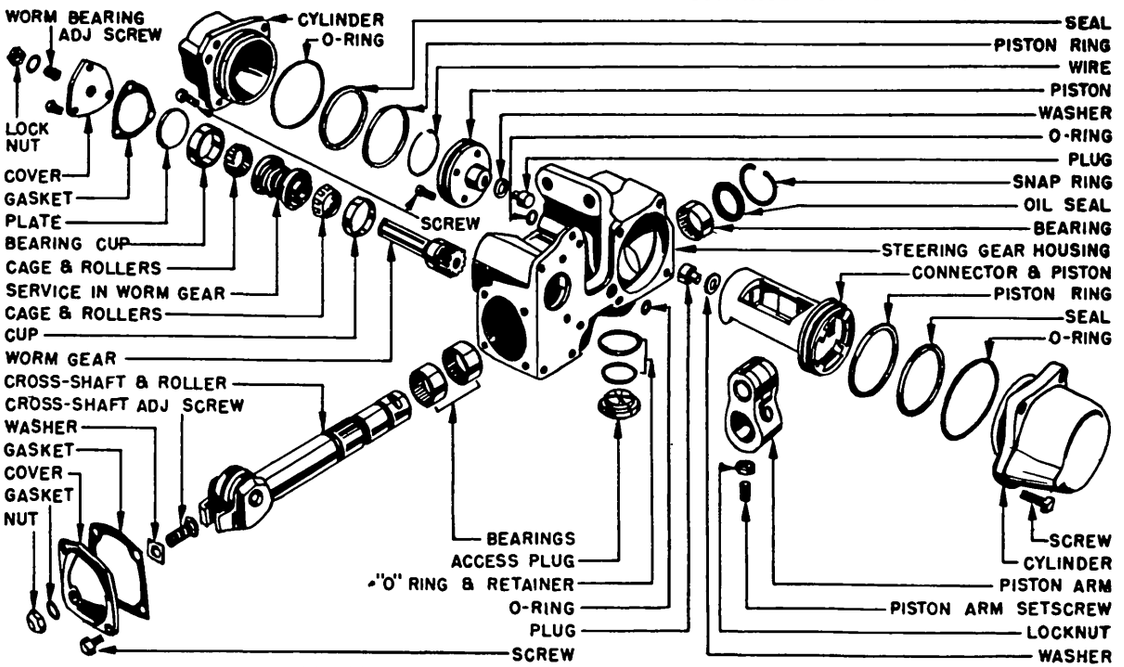
BLEEDING HYDRAULIC SYSTEM: *CAUTION—Before removing reservoir cover, carefully clean cover and adjacent surfaces to prevent possibility of dirt entering the system.*

1. Fill reservoir slightly higher than normal, place cover on reservoir.
2. Start engine and allow to run for short time to circulate oil through hoses and chuck, stop engine and refill reservoir to proper level (see below). NOTE —If gear chuck contained no oil, filling operation may have to be repeated until level remains constant.
3. With engine running at idle speed, turn steering wheel back and forth several times from extreme right to left
4. Refill reservoir to proper level (see below).
5. Re-install reservoir cover.

TESTING

HYDRAULIC PRESSURE TEST: Use special gauge C-3102 assembly which is designed to be connected to pressure hose connection at pump so that pressure can be checked while unit is operating.

1. Connect gauge C-3102 in the pressure line between pump and hose. Start engine and turn steering wheel. If gauge does not show at least 500 lbs. pressure when steering wheel is in either extreme position, check the pump by turning the shut-off valve to its closed position. If the pressure does not gradually increase as the valve is closed, the flow control valve in the pump may be stuck in an open position or the drive coupling may be broken, *See PUMP below.* If 500 lbs. pressure does show on gauge with engine idling, the pump is in good condition; and trouble is probably in steering gear assembly.



►*TESTING NOTE*—If a gauge is not available, a fairly accurate way of making the test is as follows: Start the engine and turn the wheel to both extreme positions. If the high pressure hose flexes, the pump is in good condition. Look for trouble in the gear assembly. If the high pressure hose does not flex, lack of pump pressure is indicated. See below.

TROUBLE SHOOTING

NO POWER ASSISTANCE (with engine running):

1. **Hydraulic Pressure**—Check hydraulic pressure (see Testing above).
2. **Pump**—Remove reservoir cover and with plug or finger held over center hol at top of filter start engine and turn steering wheel. If oil flows through filter, stuck flow control valve plunger is indicated. Shut off engine and free the valve as follows: Disconnect high pressure hose at the pump fitting and insert a ¼" clean blunt probe against valve. If valve moves inward 3/16" to ¼", then it was stuck open. Remove valve and clean with crocus cloth to remove foreign material or scores; reinstall and test. Pressure should be obtained on extreme turns of 500 lbs on gauge, or without gauge, the high pressure line should flex. If this does not correct condition, check coupling.
3. **Coupling**—Remove pump and coupling from generator. Remove snap ring that attaches coupling to pump shaft and remove coupling. If coupling is damaged, turn pump drive shaft at least ten revolutions. If shaft turns freely, install a new coupling on pump. Insert tongue of pump shaft into slot of coupling and fasten with snap ring. Then reinstall pump. If pump shaft binds when turned by hand, replace both pump and coupling. If generator shaft is damaged, repair generator.
4. **Drive Belt**—Check condition of the fan and generator drive belts and pulleys. Check belt adjust-

CONTINUED ON NEXT PA E

EMMER HYDRAGUIDE STEERING GEAR & POWER UNIT

HYDRAGUIDE (C nt.) (INTERNAL OIL PASSAGE)

ment. See Generator Belt Adjustment on car model page.

5. Steering Gear Assembly—Erratic lack of steering assistance (occasionally or repeatedly) may be due to broken power cylinder piston rings (phenolic rings or rubber "T" rings). Replace piston ring assemblies.

►*CAUTION—If broken rings found, or if pieces of ring noted when draining system, Oil Pump and Reservoir should be cleaned (see LUBRICATION above).*

POWER ASSISTANCE LACKING IN ONE DIRECTION (Car steers easily in one direction but greater effort required to turn in opposite direction):

1. Steering Gear Misalignment—Check and correct alignment of steering gear and steering column jacket. *See Steering Gear Alignment.*

2. Control Valve Assembly—Check all reaction and distribution valves for correct assembly and installation. Make certain all valves are clean and that bleeder hole in check valve is open.

SENSITIVE STEERING (Too much assistance—front wheels tend to turn too far or too quickly): Can be detected without turning wheels by tendency of engine to slow down, and pressure hose from pump expanding when engine accelerated (hose may also show some seepage). Test as follows:

1. Install gauge and valve (see No Power Assistance Test above). Without turning wheels, accelerate engine and note pressure. If pressure excessive (300-400 lbs.), flow control valve sticking in closed position is indicated. Correct as follows:
2. Remove flow control valve (directly behind large plug to which high pressure hose connected), clean out all foreign material and polish valve with crocus cloth. Re-install valve and check for free movement.
3. Recheck pressure. Gauge should show 30-60 lbs. when engine accelerated.

NOISY OPERATION:

1. Low Oil Level—If steering wheel is turned while engine is not running, oil will be lost through reservoir vent and air will be drawn into system resulting in noisy operation. Replenish oil supply and bleed system. *See BLEEDING HYDRAULIC SYSTEM above.*

2. Singing Relief Valve—Indicates that the steering wheel is being held in either extreme position, or against curb. Release steering wheel.

►*CAUTION: Do not hold steering gear in either extreme position and accelerate engine at same time. Excessive heat will be generated and may cause damage to pump.*

3. Banging or Cracking Noise or Thump when turning corners—Indicates loose clamp bolt on steering arm (tighten to 120 ft.lbs. using a torque wrench), loose mounting bolts, or misalignment between steering column jacket bearing and steering tube. *CAUTION*—when tightening steering gear-to-bracket bolts or bracket-to-frame bolts, alignment must be checked. *See Steering Gear Alignment.*

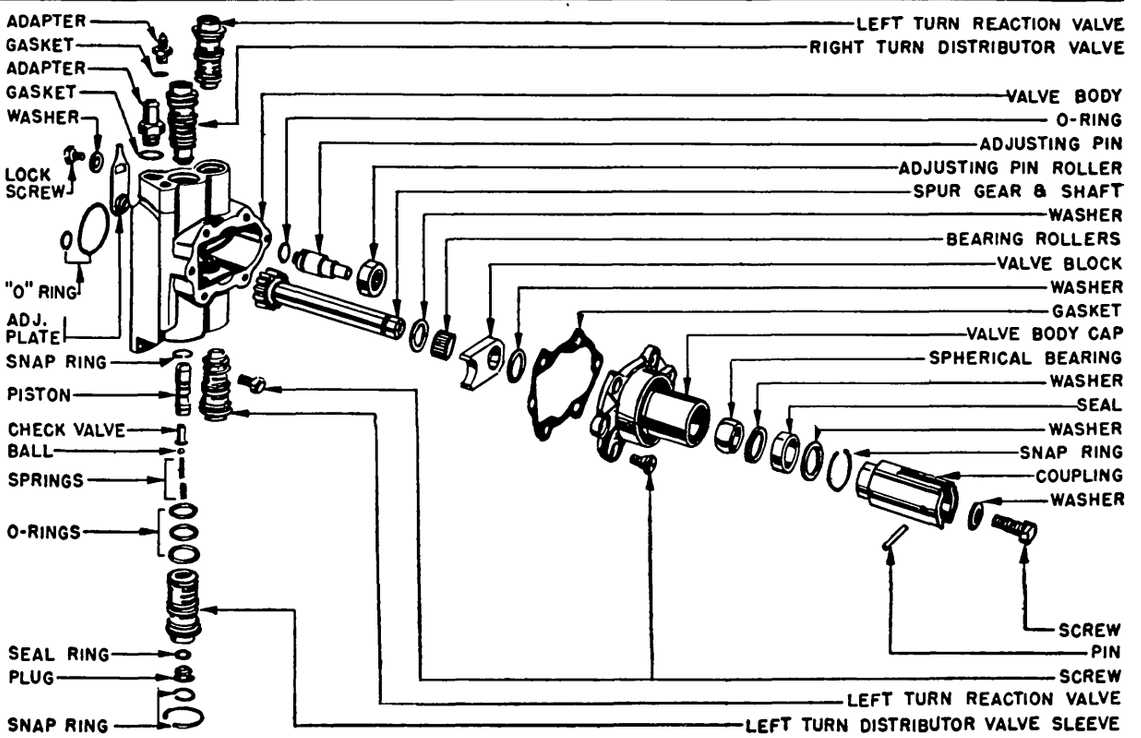
4. Valve operating gears out of adjustment. *See Spur Gear Adjustment.*

5. Rubber insulator between steering gear and steering column jacket worn or out of place.

LEAKS:

1. Between Reservoir and Pump—Remove lower plug on pump and drain reservoir. Check to see that the four reservoir to pump screws are tight. If they are tight, the leak is probably due to "O" rings not sealing. Remove the four screws and lift reservoir from pump. Replace all six "O" rings in proper position and examine pump and reservoir surfaces for flatness and freedom from surface defects. Tighten screws to 7-12 ft. lbs. torque.

2. At Banjo Fittings—Cross-over lever on gearshift may interfere with fluid lines going to gear assembly and cause leaks at banjo fittings. Loosen banjo fittings. Pry between the lines and gearshift lever rod and force lines and rods apart, allowing fitting to move a little. While holding lines apart, tighten fittings to 16-20 ft. lbs. torque.



3. Between Cylinder Mounting Lock Rings & Housing: Replace "O" ring gaskets as follows: Back off lock ring far enough to permit removal of old "O" ring, disconnect banjo oil line connections on cylinder, slip new "O" ring (use two rings if necessary) under pipe connections and stretch ring over lock ring. Apply lubriplate to "O" ring and tighten lock ring to 35-45 ft.lbs. torque.

EXCESSIVE PLAY IN STEERING WHEEL:

1. Check and adjust valve operating gears (spur gears) and steering gear worm and roller. *See ADJUSTMENT.*
2. Tighten steering gear-to-bracket bolts to 65-75 ft.lbs. torque and bracket-to-frame bolts to 50-56 ft.lbs. torque with a torque wrench. *See Hydraguide Mounting Bolt Loosening Correction.*

ADJUSTMENT

All adjustments are made with Steering Gear Unit off car. *See "Overhaul" for adjustments with Steering Gear off Car.*

GEMMER HYDRAGUIDE CONTROL VALVE ASSEMBLY

BELT ADJUSTMENT: Keep generator drive belt in adjustment (¾" deflection midway between fan and generator pulleys).

STEERING COLUMN HORIZONTAL & VERTICAL ALIGNMENT: If spacing between column and chuck is not equal, loosen bracket-to-frame bolts and shift chuck and bracket in required direction to equalize the spacing between column jacket base, grommet, and valve body face. *CAUTION*—In some instances it may be necessary to install shims between bracket and frame to obtain sufficient movement of gear for proper alignment. Shims should be "U" shaped or flat washers and placed around bracket-to-frame bolts. *DO NOT PLACE SHIMS BETWEEN GEAR AND BRACKET.*

STEERING GEAR REMOVAL

STEERING WHEEL & HORN BUTTON REMOVAL: Disconnect battery, center steering wheel in straight-ahead position. Press down on horn blowing ring ornament and turn counter-clockwise. Lift out ornament retaining spring and pad. Disconnect horn wire from terminal on travel plate and insulator assembly. Remove bushing, travel plate, horn blowing contact ring spring and triangular ground plate. Curl and push horn wire into steering gear tube to make room for steering wheel puller pilot. Remove steering wheel nut. Attach puller Tool C-612 and remove steering wheel.

STEERING GEAR ASSEMBLY REMOVAL: (1)—Remove horn blowing ring, turn steering wheel to extreme left position, and remove steering wheel. Re-

CONTINUED ON NEXT PAGE

HYDRAGUIDE (C nt.) (INTERNAL OIL PASSAGE)

move transmission position indicator lamp housing from gearshift lever housing. Remove snap ring retaining turn signal and carefully work turn signal switch housing upward until it clears column jacket. Remove cross head screws retaining upper and lower halves of shifting yoke collars together and lift off upper collar. Remove large Oilite bearing with care. Remove snap ring retaining shift lever yoke and bushings in gear shift tube.

(2)—Lift shift lever yoke upward and out of housing. Do not drop yoke bushings in tube. Otherwise it will be necessary to disassemble column jacket in order to recover bushings. Remove lower collar from steering column jacket.

(3)—Remove steering column jacket toe pad, floor mat, clutch, and brake pedal pads. Remove clutch and brake pedal floor pan toe board cover. Remove clutch pedal horseshoe lock, slide pedal sideways and toward rear of car to allow for clearance of steering assembly removal.

(4)—Remove shift linkage clevis pin from bellcrank assembly in engine compartment. Disconnect directional signal indicator wires and remove horn wire connector from steering column. Remove two steering column to instrument panel screws.

(5)—Remove column jacket shroud assembly by removing column and shroud assembly down and away from gear chuck. Disconnect pressure and return hose from steering gear housing assembly, and cap the fittings.

(6)—Raise car off floor and remove left front wheel and drag link. Remove fender side shield. Remove steering gear chuck-to-frame bracket attaching capscrews. Install front wheel, lower car and remove steering gear assembly through toe board opening.

STEERING GEAR OVERHAUL

►*DISASSEMBLY NOTE*—Drain assembly by removing piston arm screw access plug at bottom center of cylinder housing. Remove caps from inlet and outlet oil passages. Turn steering gear coupling to extreme right and left, while draining oil, to force out all oil. Thoroughly clean all surfaces of unit.

DISASSEMBLY (Valve Assembly & Steering Gear Tube): (1)—Remove capscrew from steering arm and remove arm from steering cross shaft. Remove four bolts attaching valve body and valve cap assembly to housing, and lift valve body and cap from housing. *(CAUTION*—Valve body is made of die-cast aluminum and must be handled carefully to prevent damage to cover or its mating surfaces). Remove five "O" ring oil seals from valve body face.

►*VALVE REMOVAL CAUTION*—Each valve body port boss is marked to aid in reassembly of valves in correct position. Work carefully when removing valves, as internal parts of valves may become loose and fall into housing. To prevent improper assembly, units of valve assemblies should be cleaned separately and placed in separate containers. ***Valve parts are a select fit with each other and ar not interchangeable.***

(2)—Remove outer snap ring retaining each valve assembly in valve body, and pry out each valve assembly.

►*VALVE POSITION IDENTIFICATION MARK CAUTION*—Valve position identification marks on valve body port bosses indicate the number of "O" ring seals used on each valve as follows: (a) Right Turn Reaction Valve (Lower Right)—two "O" rings. (b) Left Turn Distributor Valve (Lower Left)—three "O" rings. (c) Left Turn Reaction Valve (Upper Right)—two "O" rings. (d) Right Turn Distributor Valve (Upper Left)—three "O" rings.

►*VALVE INTERCHANGE NOTE*—Right and left valves are interchangeable as an assembly, if correct number of "O" ring seals are installed on valves for each location.

(3) Remove valve piston assembly from valve sleeve and remove check valve. Inspect valve balls, springs and valve body bleed holes for obstructions. Clean all parts in solvent and replace "O" ring oil seals. Assemble valves in sleeves, making sure each valve is clean and is assembled in its respective position in valve sleeve. Remove the six valve body cap recessed head screws and star washers. Remove valve body cap and gasket from valve body housing.

(4)—Clamp steering tube coupling in vise and remove capscrew and washer holding coupling to steering shaft.

►*CAUTION—Do not clamp tube gear or valve cap body casting in vise. Clamp only the coupling to prevent damaging the assembly.*

(5)—Mount Puller Tool C-3132 (adapted to C-293 puller stand) to valve body cap and steering gear tube coupling assembly. Clamp puller in vise and remove coupling from gear tube. Slide steering gear tube and valve block assembly out of valve body cap. Remove oil seal snap ring and lift out oil seal outer washer.

(6)—With Remover & Installer Tool C-3269, drive the spherical bearing, steering gear tube oil seal and inner washer from valve body cap. Inspect bearing, roller, and valve block for damage, and wear. Clean all parts with solvent and blow dry with air.

Steering Gear Cylinders and Power Pistons: (1)—Remove cylinder-to-housing attaching capscrews. Thread cylinder removing studs, Tool C-3336 evenly into threaded cylinder flange holes until studs bottom in housing. Continue threading studs inward, evenly, until cylinder is free from housing. Remove large "O" ring seal from outer machined surface of cylinders, and small "O" ring seals from steering gear housing face.

(2)—Center piston arm in center of steering housing and remove piston screw retaining wire from pistons. Remove three piston-to-connector attaching capscrews and remove piston from connector. Remove connector and piston assembly from housing. Remove the neoprene seals and nylon thrust rings frim pistons. Carefully inspect rings for damage.

►*PISTON RING CAUTION—If piston rings are damaged or appear to be in doubtful condition, rings should be replaced.*

(3)—Loosen piston setscrew locknut and remove setscrew. Remove steering gear shaft cover adjusting screw locknut and nylon washer. Turn steering gear shaft to center position. Remove the four shaft cover attaching capscrews and copper sealing washers. Withdraw steering shaft from housing sufficiently to allow for removal of cover. Turn shaft cover adjusting screw in. Slide adjusting screw and cover out of slot in end of shaft. Remove cover and gasket. NOTE—A nylon washer is being used instead of the adjusting screw star washer.

(4)—Withdraw steering shaft from piston arm and remove piston arm assembly from steering gear housing. Loosen worm gear shaft cover adjusting screw locknut. Remove the three cover attaching screws and lift cover and screws from housing. Remove the steering gear shaft outer oil seal retaining snap ring with Remover Tool C-3137. Remove outer oil seal.

(5)—Remove the thrust pad, cup bearing, and worm assembly from housing. Remove adjusting screw locknut, nylon washer, and adjusting screw from worm cover. Clean housing and parts thoroughly in solvent and blow dry with air. Inspect worm shaft and gear, bearings, cups, bearing rollers, and other parts.

(6)—Inspect the three steering shaft needle bearings in housing. If rollers do not rotate freely, or if bearings are damaged, remove steering shaft center and inner bearings by driving bearings toward outer bearing with Tool C-3114. Remove outer bearing by driving bearing toward inside of steering gear with Driver Tool C-3113.

REASSEMBLY (Steering Gear Cylinders and Power Pistons): (1)—When installing steering gear shaft bearings in steering housing, bearings should be always driven against lettered end of bearing cage. Install center bearing in housing from steering gear arm side of housing. Drive bearing into housing with Driver Tool C-3114, until bearing is flush with inner face of housing.

(2)—Install shaft outer bearing, drive bearing with Driver C-3113, until bearing is approximately .050" below outer seal counter bore of housing.

(3)—Lubricate worm gear bearings and cups with lubriplate. Install worm gear, outer bearing, cup and thrust pad in housing. Lubricate gasket with Lubriplate and install gasket in position in housing. Remove adjusting screw from worm gear cover and place cover on steering housing. Install the three cover attaching capscrews, with copper sealing washers under screw heads. Tighten to 20 ft lbs. Install adjusting screw in cover, nylon washer and locknut on adjusting screw. Turn locknut down until it barely touches the washer.

Worm Shaft Bearing Adjustment—Turn adjusting screw clockwise until worm rotates freely without binding from one extreme to opposite extreme. ***(CAUTION—The worm gear when properly adjusted, should rotate freely in bearing cones without binding, and should also be sufficiently tight to eliminate any free play between shaft and bearings).*** Hold adjusting screw and tighten locknut to 25 ft. lbs. Recheck worm shaft bearing adjustment after tightening adjusting screw and locknut.

CONTINUED ON NEXT PAGE

HYDRAGUIDE (C nt.) (INTERNAL OIL PASSAGE)

Checking Piston Arm and Plug Clearance—Assemble piston on piston connector outside of steering housing. Check clearance between piston plugs and piston arm roller. ***It is important that this clearance be held as close to zero as possible.*** This can be controlled by various thickness of shims inserted between piston and piston plugs. These shims are available for service in a number of sizes varying in steps of .001" thickness. After checking the above clearance, disassemble piston and connector, leaving plugs in piston. Remove connector from piston arm.

(4)—Make sure steering shaft rollers rotate freely and that the housing oil passages and piston arm are clean. Place piston arm in position in housing so that splines on shaft will mesh with splines on piston arm. Insert steering shaft into piston arm until shaft is positioned in housing.

(5)—Install steering gear shaft cover gasket on housing after coating with Lubriplate. Install steering gear shaft cover and adjusting screw assembly in slot in end of shaft. Turn adjusting screw counter-clockwise to draw shaft cover up to housing. When cover is properly seated on housing, install the four cover attaching capscrews and copper sealing washers under head of each screw. Tighten screws evenly to 20 ft. lbs. Install nylon washer and locknut on shaft adjusting screw until nut barely touches nylon washer. Install gear shaft outer oil seal (lip of seal facing inside housing) with Sleeve Tool C-3136. Install outer seal snap ring (beveled side out). Position snap ring so that ring opening is pointing downward toward bottom of unit so that snap ring can be removed readily from under car when necessary. Make sure snap ring is properly seated in groove. Install steering gear arm on steering shaft. Tighten arm clamp bolt to 200 ft. lbs.

Steering Gear Shaft Adjustment—***(CAUTION—When making cross shaft adjustment, always remove power arm access plug and loosen power arm set screw before attempting to adjust cross shaft).*** Set worm gear and piston arm at center position. Hold worm at center with one hand. With other hand on pitman arm, check backlash between gear and worm in both directions. Turn shaft adjusting screws so that no backlash will be felt while worm is turned approximately 45 degrees, either side of center line.

►***CAUTION: Clearance should be at a minimum at the degree positions without binding. Do not adjust cross shaft roller and worm too tightly.***

Hold adjusting screw in the adjusted position and tighten locknut to 20-25 ft. lbs. Install piston arm adjusting lock screw and locknut. Tighten screw to 30-35 ft. lbs. and tighten locknut to 20 ft. lbs. Lubricate and install a new "O" ring seal on access plug, and tighten plug to 35 ft. lbs.

(6)—Center piston arm in steering housing. Install piston and piston connector assembly in housing, with piston plug bearing against piston arm and roller. Assemble the removed piston and plug assembly to opposite side of piston connector. Tighten Allen screws to 16-20 ft. lbs. Install piston screw retaining lock wires. ***CAUTION***—New "O" ring seals, gaskets, copper and nylon washers should be used each time unit is disassembled.

(7)—Lubricate neoprene "D" ring (cross section of ring is shaped like a "D"), and nylon thrust rings on piston with Lubriplate. Make sure that tapered side of thrust ring fits against tapered side of piston ring groove.

►***NOTE: Tapered side of thrust ring fits against tapered side of piston ring groove.***

(8)—Remove cylinder removal screws from cylinder flange, check face for burrs, clean and lubricate cylinder bores. Lubricate cylinder "O" ring with Lubriplate and install ring on outer machined section of cylinder. Install oil passage "O" rings on housing-to-cylinder oil passages. With pistons located in center of housing, place cylinders in position on housing. Work carefully to avoid damaging "O" rings during installation. Align cylinder holes with holes in housing. Install capscrews and tighten screws evenly to 30-40 ft. lbs.

Valve Assembly & Steering Gear Tube: (1) Install spherical bearing in valve body cap and place oil seal inner washer in body against bearing. Lubricate steering tube gear oil seal with Lubriplate and install seal in valve body (with lip of seal inward). Using Remover & Installer Tool C-3269, drive seal in valve body cap sufficiently to allow for installation of outer washer and snap ring. Install oil seal outer washer and snap ring, making sure snap ring is properly seated in valve body cap. Place steering gear tube and valve block assembly in valve body cap. Install coupling on steering tube gear and secure with capscrew and washer. Tighten screw to 20 ft. lbs.

►***VALVE BLOCK ADJUSTING PIN NOTE***—To replace or inspect needle roller bearings in adjustment pin roller, lift bearing and roller off pin as an assembly from shaft. To replace needle bearing in roller, use one end of Driver Tool C-3141 to remove bearing and the other end to install bearing. If leakage around valve block adjusting pin is apparent, remove adjusting plate capscrew, washer and adjusting plate. Remove valve block adjusting pin from inside valve body and remove "O" ring seal from adjusting pin. Lubricate new ring seal with Lubriplate and install ring on adjusting pin. Install pin in valve body. Do not damage ring when installing. ***(CAUTION—When assembling valve block adjusting pin in valve body, locate offset side of pin away from steering tube gear. The adjusting plate should not be installed on adjusting pin until unit is completely assembled).*** Inspect steering tube gear thrust button located in valve body for wear and replace if necessary.

(2)—Place adjusting pin roller on pin and lubricate valve body cap gasket. Install valve body cap assembly on valve body. Install the six recessed head screws and star washers in valve body cap. Tighten screws to 20 ft. lbs.

(3)—Lubricate "O" rings on valve assemblies with Lubriplate and install valves as indicated on valve body ports. Install snap rings with beveled edge out. Make sure snap rings are properly seated in grooves. Lubricate the five valve body-to-housing "O" ring seals and locate them in valve body.

(4)—Set worm gear and piston arm to center position. Locate steering tube coupling slot in vertical position and assemble valve body to steering gear housing. Install valve body to housing attaching screws and lockwashers. Tighten screws to 40 ft. lbs.

Spur Gear Adjustment (Unit off Car)—With worm gear and piston arm centered, turn tube coupling slot in vertical position. Install adjusting plate on adjusting pin. Rotate adjusting pin and plate until no backlash is felt at steering tube coupling. Hold lock plate in adjusted position. Install and tighten capscrew to 12 ft. lbs.

STEERING GEAR INSTALLATION

STEERING GEAR ASSEMBLY INSTALLATION: Reverse removal procedures.

HYDRAULIC PUMP OVERHAUL

See "Chrysler, DeSoto, Dodge, Plymouth (Single Rotor) Pump" under "Power Steering Pumps".

CHRYSLER. DE SOTO, DODGE, PLYMOUTH 1954-56 "CO-AXIAL"

Chrysler (1954-56)
DeSoto (1954-56)
Dodge (1954-56)
Plymouth (1954-56)

►CHANGES & CORRECTIONS

►*GEARSHAFT PRODUCTION CHANGE & ADJUSTMENT CAUTION:* Early cars (prior to approximately Jan. 1955) have a gearshaft with teeth having **unequal widths.** Later cars, have a gearshaft with teeth of **equal width.** The later type shaft is identified by a "O" stamped on the steering arm end of the shaft, and is adjusted in a different manner than the early type shaft.

►*1955 POWER STEERING PISTON PRODUCTION CHANGE:* Effective production March 18, 1955 a new type piston has been used. New piston has a narrow ring groove, a "D" type ring seal, Part No. 1634561, and eliminates the use of a steel ring. Kit, Part No. 1692656, is available to service earlier type piston with "L" type piston ring and steel ring. New "D" type seal should be used to correct a "lack of feel" condition.

►*1955 DODGE JERKY OPERATION OF POWER STEERING GEAR CORRECTION:* After generator drive belt has been adjusted (See Generator on Car Page), adjust fan drive belt so that a maximum of 1/4" deflection is obtained when applying a 10 lb. pull with spring scale at middle of widest belt span.

► *1955 CHRYSLER, DE SOTO, DODGE, PLYMOUTH CO-AXIAL STEERING GEAR PRODUCTION CHANGE & OVERHAUL CAUTION:* On later steering gears, a new "D" section rubber piston ring seal without metal spacer or backing ring was used with a new piston as listed below. This ring replaced original "L" section ring seal which must not be used at any time. New "D" section piston ring seals can be used with original piston if installed as follows:

"D" Section Piston Ring Seal Installation (On Original Piston) – Remove old "L" section piston ring seals and metal spacer or backing rings from piston, discard the "L" type neoprene rings. Install new "D" section rings on original piston, then install original metal spacer rings behind "D" rings (toward center of piston). *NOTE* - If necessary to replace the original metal spacer rings, use Assembly No. 1692657 (contains "D" rings and metal spacers).

Co-axial Power Steering Piston Assy.

Part	New Part No.	Old Part No.
Power Piston	1639169	1554388
"D" Sect. Ring Seal	1618789	1531420

► *1956 POWER STEERING GEAR WORM NUT PRODUCTION CHANGE:* A new worm nut, Part No. 1673971 having a hexagonal shape and a built-in staking collar is being used on steering gears identified by the date 12-15-55 or later stenciled on housing side of flange, where upper housing bolts to lower housing. The present tool, C-3320 can be modified to accomodate both early and later type nuts by removing the two opposing lugs.

DESCRIPTION

Components of this system have been fitted into an elongated, tubular-shaped housing, concentrically located about the axis of the steering column. Unit fastens to steering column at underside of instrument panel and extends down through firewall to a bracket bolted to top of frame, System incorporates a worm and worm connector and a rack and sector gear. Worm and worm connector acts in a manner similar to a bolt and nut assembly with left hand threads. Rotation of the worm causes linear (axial) motion of the worm connector. Fastened to worm connector, in succession, are an upper piston rod, piston, and a lower piston rod, all concentric to the steering column axis. A rack, machined in the lower portion of the lower piston rod, meshes with a sector gear. This combination produces rotation of the steering gear arm, actuating steering linkage. The conventional system of steering linkage is used. Hydraulic elements of the system include:

Hydraulic Power Mechanism—Consists of a double-acting piston, a spool valve (which fits inside the piston), and an hydraulic reaction chamber (which gives the driver the "feel" of the road). Axial positioning of the valve directs high pressure oil to one side or the other of the double-acting piston. At the same time, valve movement opens an oil return line which carries oil from low pressure side of the piston to the oil reservoir. The direction of oil flow (which depends on direction of steering wheel rotation) is such that hydraulic force is added to the driver's effort and is transmitted through the rack and sector gear to the steering gear arm.

Pump and Reservoir Assembly—Consists of generator driven oil pump with pressure relief valve and flow control valve, and a filter with oil reservoir. Flow control valve limits oil flow to a predetermined maximum (2 gallons per minute) and thus holds the horsepower required to drive the oil pump to a minimum.

ADJUSTMENT

SELECTOR LEVER & TRANSMISSION SHAFT LINKAGE: Loosen gear shift rod lever clamp bolt. Position selector lever in low or reverse, then holding the gear shift rod lever and spacer flush against gear housing, tighten nut. Place selector lever pointer lever in neutral position on indicator dial at top of steering column. Disconnect gearshift control rod at bellcrank on transmission. Make sure manual control lever (at the transmission) is in neutral position (second detent position from rear of vehicle). With selector lever pointer still in neutral position, adjust the gearshift control rod to the required length for a free fit in the lever of the bellcrank, then reinstall rod. Operate selector lever through all indicator positions. Road test vehicle.

1954 MODELS

GEAR SHAFT ONLY (UNIT IN VEHICLE): Remove drag link from steering gear arm. One man should be seated in vehicle to turn steering wheel and record positions while the other does the adjusting. Start engine and turn steering wheel from one extreme position to the other, and count the number of turns (this should be approximately 3 3/4 turns). Then, starting with steering wheel setting at one end of the travel, turn it back approximately 1 7/8 turns (center position). The steering gear shaft, when correctly adjusted, will have an arc of no backlash for at least 300° but less than 340° (or 150° either side of center). When making this adjustment, it has been found to be more accurate to turn the gear into a backlash position and adjust gear mesh to a point where backlash disappears. As an aid in establishing the 150° positions of the steering wheel when making the gear shaft adjustment, it is suggested that the clock system be used. In using system 12 o'clock would represent center position and each hour would represent 30°; therefore the 150° position would be at 5 o'clock if steering wheel was turned to right (clockwise). If turned in the opposite direction (counter-clockwise) from 12 o'clock, the 150° point would be at 7 o'clock. With steering gear in centered position, turn steering wheel to 150° (5 o'clock) and adjust, if necessary, into a backlash position. Then, using steering gear arm for checking, reduce backlash to zero at the 150° (5 o'clock) point.

►*CAUTION: When checking for no backlash, use a very light (feather) touch with a slight wrist motion. Greater effort to move the steering gear arm back and forth when checking may result in moving other parts of the gear and give a false sense of true gear shaft to rack clearances. To further aid the sense of touch, a pair of vise grips may be clamped ont the steering gear arm.*

Again with steering gear in centered position, turn the steering wheel in the opposite direction (counter-clockwise) past the 150° (7 o'clock) point into backlash position. Then turning the steering wheel back slowly toward center and using steering gear arm, check for point at which backlash disappears. If it disappears at the 150° (7 o'clock) point, the steering gear is properly centered and adjusted to the center of no backlash arc. If backlash did not disappear until after the 150° (7 o'clock) point, the steering gear is too loose and gear not properly centered to no backlash arc. To center a gear in this condition with the center of no backlash arc, the jacket and shroud assembly will have to be removed and position of tube coupling on worm shaft changed as follows: Turn coupling back to center position. Then divide the difference of 60 (2 hours 7 to 9) in half, which would be 30° (1 hour). Since the shorter distance of no backlash travel was in a counter-clockwise direction, remove coupling from worm shaft and turn it clockwise 30 (1 hour) so that when reinstalled the slot in the coupling will be 1 o'clock. Then turn coupling to 12 o'clock and gear will be centered to center of no backlash arc. Again starting from center, turn the coupling to 150° (5 o'clock) and adjust into a backlash position. Then, using steering gear arm for checking, reduce backlash to zero at the 150° (5 o'clock) point.

►*CAUTION: Too loose adjustment will result in free play and a noisy gear. Too tight an adjustment will affect recoverability and will cause excessive wear of the gear teeth.*

CONTINUED ON NEXT PAGE

1954-56 "CO-AXIAL" (C nt.)

Recheck adjustment by turning coupling counter-clockwise past the 150 (7 o'clock) point in the backlash position. Turn coupling back slowly toward center and backlash will disappear at the 150° (7 o'clock) point if coupling was properly centered to center of no backlash arc. (NOTE–If backlash had disappeared at 6 o'clock instead of 7 o'clock it would have indicated 330 of no backlash arc, which is permissible, and position of coupling would not necessarily have to be changed. Should it be desired that the position be changed, make sure that slot in coupling, when installed, is relative to the center of no backlash arc and not the overall travel (3 3/4 turns of the steering gear). When adjustment is completed, stop engine and tighten adjusting screw locknut to 40 ft. lbs. torque. Install drag link to steering gear arm and tighten nut to 45-75 ft. lbs. torque. Check centered position of steering wheel with straight-ahead position of front wheel. If not centered properly, correct by adjusting tie rod ends.

CONTROL VALVE: *CAUTION–Since considerable effort is involved in adjusting the control valve, it is sugg sted that it be c rtain that the difficulty lies within th c ntr l valv before making the adjustment. If diagnosis indicates that gear assembly is not cent red hydraulically, and all other possibilities hav been check d, th n pr ceed as follows:*

1) Remove steering gear assembly (See "Removal & Installation").

2) Remove worm housing filler plug and drain lubricant through filler hole. Attach holding fixture C-3323 to unit and place in vise. Remove tube coupling screw, lockwasher and washer from center of coupling. Using tool C-3392, remove coupling from worm shaft. *(NOTE*–Tool C-3112 may also be used to remove coupling. However, to accomplish this, necessitates the cutting of one adapter plate SP-1409 in half and using the two pieces instead of the two plates). Remove worm housing oil seal.

3) Unlock bearing adjusting nut by bending tang of lockwasher. (NOTE–Only one tang locks nut in position). Place tool C-3320 over worm shaft followed by C-3319. Holding worm stationary remove worm bearing adjusting nut, lockwasher and thrust washer. Remove worm outer bearing race and bearing roller from worm. Remove the three worm-to-gear housing screws and belleville washers. (NOTE–Concave side of washers are against housing when installed). Remove worm housing and "O" ring.

►*CAUTION: Do n t b ttom worm shaft in the outward dir cti n when rem ving or installing. Bottoming th w rm shaft may damage the ball guides which w uld result in a tight r r ugh operating worm.*

4) Remove the two worm connector ball guide clamp screws and lockwashers. Remove guide clamp. Using care not to lose any of the worm balls, carefully remove ball guide from the worm connector.

►*CAUTION: Balls us d in w rm c nn ct r are a s lect fit with ach oth r. If any ar lost or damaged, it is rec mmended that a compl t s t (40) be install d.*

5) Turn worm connector over and carefully thread the remaining worm balls out of the worm connector by turning the worm in and out. Remove worm from connector.

►*CAUTION: If h using h ad has becom s parated from gear housing, make sure the "O" ring is in position between housing head and gear housing.*

6) Secure housing head to gear housing by guiding tool C-3324 (Dummy Housing) over rails on worm connector until it is flush with gear housing. Install the three washers and screws, draw down evenly and tighten to 25-30 ft. lbs. torque.

7) Secure steering gear arm from stock or remove the one from vehicle. Install steering gear arm, lockwasher and nut. Tighten nut to 30-40 ft. lbs. torque. Install the 3/4" hose adapter fitting in the return outlet of the gear housing. Connect return hose (large diameter) C-3318 to the 3/4" adapter fitting. Connect small end of C-3211 hose to the 5/16" adapter (pressure) in gear housing. Install pressure gauge C-3309 in pressure side of pump. Connect the pressure hose C-3211 to fitting at the shut off valve. Connect the return hose C-3318 to reservoir and tighten all fittings. Thoroughly clean the outside of the reservoir and remove cover or filler cap.

8) To maintain oil in the reservoir to normal level while hydraulically centering the steering, add sufficient oil over and above the normal oil level of the reservoir to approximate the volume in the test hoses.

9) Open the shut off valve at the gauge and start engine. Allow engine to operate long enough for pump to circulate oil through steering gear assembly and test hoses.

10) Place alignment cap and dial SP-2619, which is part of tool C-3325, over worm connector and lock in position by tightening thumb screw. Insert extension rod SP-2621 through alignment cap and over valve adjusting rod in bottom of worm connector. Tap extension rod lightly so that it is a tight fit on valve adjusting rod. Position adjusting handle SP-2620 on extension rod so there is approximately 1/16" clearance between handle and alignment cap, then lock in place by tightening set screw in handle Adjust valve by turning handle until the pump pressure registered on the gauge is at a minimum.

►*CAUTION: Do not apply heavy pressure on the adjusting tool as valve rod may twist off in assembly.*

11) Carefully rotate valve adjusting handle SP-2620 to the right until the piston bottoms in the gear housing. Then, rotate valve adjusting handle to the left until the piston bottoms in the opposite direction. Repeat the rotation of the valve adjusting handle first to the right and then to the left until piston bottoms each time. This operation purges the air from the gear housing.

12) Check the oil level in the reservoir and refill to the required level.

13) With engine idling, close the shut off valve and check pump pressure. The gauge should read approximately 750 psi. **Open shut off valve.**

Cent ring Contr l Valv –Turn valve adjusting handle SP-2620 until the steering gear arm reaches approximately the center of its travel and minimum pressure is again noted *(CAUTION–Adjust the gear shaft into a backlash condition at center of gear travel. Make sure that xtension rod and tool handle fit tight on the adjusting rod. Turn valve adjusting handle in on direction until the st ering gear arm just starts to move. Note degree of valve adjusting handle on dial. Then, without removing handle, turn it in the opposite direction until steering gear arm starts to move at the same rate of speed in the opposite direction and again note the degree of valve adjusting handle on dial. Next, turn valve adjusting handle to center of the degrees required to move arm in both directions. Recheck to make sure adjustment is correct).* Stop engine, remove valve adjusting handle, extension and alignment cap. *(CAUTION–Do not change position of valve adjusting rod when removing tool. Do not disconnect test hoses at this time).* Remove the three screws from tool C-3324 (Dummy Housing), and carefully slide tool from worm connector assembly.

Required Re-Assembly Operations After Adjusting Control Valve–Insert worm shaft into connector and visually align the **upper** portion of the spiral grooves with the ball guide holes. Insert 30 balls into lower hole by tapping them gently (use rubber end of a lead pencil or similar object) while slightly oscillating the worm. *(NOTE*–When the 30 have been inserted, they should be visible in the other hole). Place the remaining balls (10) in either half of the worm connector ball guide. Grease end balls to help hold them in place and add other half of ball guide assembly. Insert assembly into holes until it seats on worm connector. Place ball guide clamp into position on ball guide and install the two lockwashers and screws. Tighten to 10-12 ft. lbs. torque. Check operation of worm making sure it is free to oscillate. Caution should be exercised not to bottom worm in the outward direction, otherwise damage to the ball return guide may result and cause a rough or tight operating worm. Lubricate worm connector rails with Lubriplate. Lubricate housing head "O" ring with Lubriplate and install on housing head pilot opposite piston side. Drop inner bearing into housing and hold in place, rotate connector so ball guide is in downward position and pilot worm housing over rails on worm connector until flush with gear housing.

►*CAUTION: Worm housing cannot be installed if bearing is installed on worm shaft prior to installing housing.*

Install the three screws and belleville washers, draw down evenly and tighten to 25-30 ft. lbs. torque. Lubricate worm outer bearing roller with Lubriplate and install in bearing cup. Slide thrust washer over worm and against outer bearing race and follow with worm bearing nut lockwasher. Turn worm shaft out until lower race seats in bearing. Install worm housing bearing adjusting nut (tapered end first). Place tool C-3320 over worm shaft followed by tool C-3319. Then using tool C-3319, with a torque wrench, turn worm shaft in a clockwise direction to 20 ft. lbs. torque against inner bearing. While holding worm shaft at this point against inner bearing, use tool C-3320 with another torque wrench and tighten adjusting nut to 15 ft. lbs. torque. Rotate worm shaft

CONTINUED ON NEXT PAGE

1954-56 "CO-AXIAL" (C nt.)

several times to insure proper seating of bearings. Next, loosen adjusting nut and again using tool C-3319 with torque wrench, hold shaft at 5 ft. lbs. torque (clockwise direction) against inner bearing and retighten adjusting nut to **5 inch pounds torque.** Lock adjusting nut in position by bending tang of lockwasher to index with slot in the nut. (NOTE–Only one tang needed to lock adjusting nut).

►*CAUTION: Too loose adjustment will result in free play before steering is accomplished. Too tight an adjustment will result in erratic steering and lack of returnability.*

Using driver C-3317, drive worm housing oil seal (lip of seal in) until it is seated against worm housing. Add 18 ounces of SAE-10W oil to the worm housing through worm bearing filler hole. Keep gear assembly in a level position to facilitate filling. Install worm housing filler plug and tighten to **50 inch pounds torque.**

►*CAUTION: It is very important that the worm housing be filled since there is no hydraulic connection between the worm and gear housings.*

CENTERING STEERING TUBE COUPLING & ADJUSTING BACKLASH BETWEEN GEAR SHAFT & RACK TEETH: With unit off car, turn worm shaft from one extreme of its travel to the other and count the number of turns; this should be approximately 3 3/4 turns. Then starting with the worm shaft setting at one end of travel, turn it back 1 7/8 turns (approximately center position). With steering gear centered as above, install the tube coupling with the slot in a vertical plane in the installed position of the gear assembly. **Do not install screw and washer at this time.** Then proceed as for adjustment of "Gear Shaft Only (Unit in Vehicle)" above noting the following:

1) Slot in coupling, when installed, must be relative to the center of no backlash arc and not the overall travel (3 3/4 turns of the steering gear). If installed incorrectly, and the steering gear is installed in vehicle, the jacket and shroud assembly will have to be removed in order to correct.

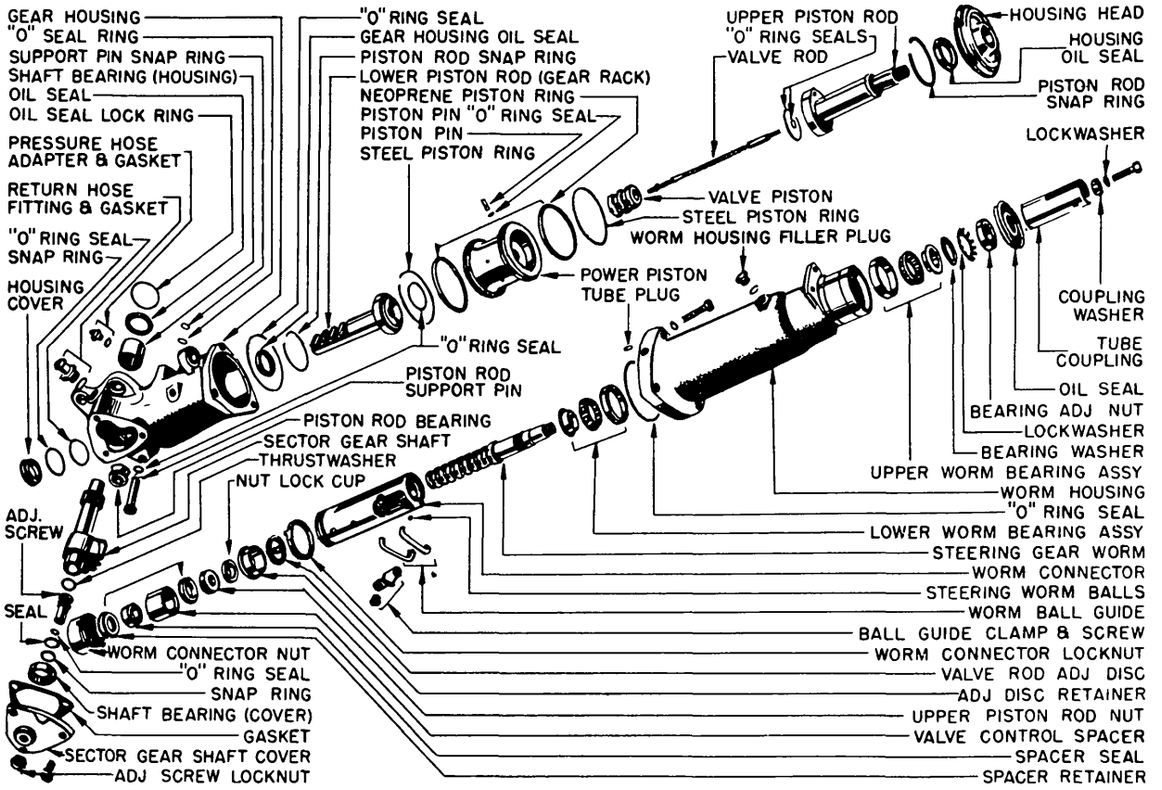
2) When adjustment completed, stop engine and tighten adjusting screw locknut to 40 ft. lbs. torque. Install coupling screw and lockwasher and tighten to 15-20 ft. lbs. torque.

3) Disconnect C-3211 and C-3318 hoses and remove adapters from gear housing. Install pressure hose connector and gasket, tighten to 18-22 ft. lbs. torque. Install return hose connector and copper gasket, tighten to 25-30 ft. lbs. torque. Cap fittings to prevent loss of oil.

4) Remove steering gear arm (to permit installation of unit in vehicle).

5) Remove holding fixture C-3323.

6) Refer to "Required Re-Assembly Operations After Adjusting Control Valve" above.



1955-56 MODELS

GEARSHAFT ADJUSTMENT: *(Early 1955 Cars - See Production Change & Adjustment Caution above)* - Check steering for being properly centered by turning the coupling in each direction from center. Pitman arm backlash should become evident at equal distances in both directions when turning from center. It may be necessary to reposition the coupling to obtain equal travel in both directions in which case it will be necessary to readjust pitman arm backlash.

GEARSHAFT ADJUSTMENT: *(Late 1955 & 1956 Cars - See Production Change & Adjustment Caution above)* - Center the steering tube coupling or steering wheel to the overall travel of the steering gear. With gear in center position, loosen adjustment screw in end of shaft opposite pitman arm until there is some backlash. Slowly turn adjusting nut in until the backlash disappears. **Turn the adjusting screw in ¼ of a turn and lock in position.** *CAUTION - Use a very light touch on steering wheel when checking for backlash.*

►*1955 LATER TYPE GEARSHAFT INSTALLATION ON EARLY MODELS WITH FIRST TYPE GEARSHAFT:* Later type gearshaft can be installed on early cars without changing the lower piston rod. If new shaft is used, the later type adjustment must also be used.

►*IDENTIFICATION OF EARLY 1955 CARS WITH LATER TYPE GEARSHAFT (Installed in field):* If difficulty is experienced in adjusting the gearshaft on early cars, the following check may be made to determine if later type gearshaft installed. Center steering wheel and tighten adjusting screw until a small amount of backlash is felt, then turn coupling or wheel to either extreme limit. If backlash increases, it is the early type gearshaft.

1954-56 CHRYSLER & DE SOTO "CO-AXIAL" POWER STEERING GEAR

Installing Coupling at Center: Install steering tube coupling with slot in coupling in the vertical plane. There are no master serrations on either worm shaft or the coupling. A mark is scribed on the coupling which must be set at 12 o'clock when the steering worm shaft is at center so that the steering tube master serration will be in position to allow for proper installation of steering wheel.

MANUAL CONTROL VALVE NEUTRAL POSITION ADJUSTMENT (Power Steering Unit Removed): With unit secured in a vise or suitable fixture, connect test hoses to hydraulic pump on car and to steering assembly. Remove oil reservoir cover. Start engine and operate at idle. Fill reservoir to level mark and allow system to warm up *(CAUTION–Oil level must be maintained above filter while hydraulically centering valve).* Insert manual control valve centering tool C-3445 (slotted end first) into worm shaft and engage slot in tool with tang on control valve operating rod (tool can be rotated by using a tap wrench). *If pitman arm moves to one extreme or the other and stays there, rotate tool in either direction until arm starts to move. Slightly rotate tool in opposite direction until arm stops moving.* Install a 1 7/16" socket on a torque wrench and place on pitman arm retaining nut. Rotate gear

CONTINUED ON NEXT PAGE

1954-56 "CO-AXIAL" (C nt.)

shaft in both directions from one extreme to the other The torque required should be the same in both directions Where torque is higher in one direction than in the opposite, rotate the valve adjusting tool slightly in the opposite direction to the direction in which the pitman arm has the highest torque reading *(Change valve position in slight variations to prevent over adjusting).* When torque is the same in both directions, remove tool

MANUAL CONTROL VALVE NEUTRAL POSITION ADJUSTMENT (P w r St ring Unit in Car): *(NOTE–Th following proc dur can be used when it is difficult to rotat th st ring wheel in one direct ion but not in th oth r, or wh r the wheels turn of their own accord. B for proc ding with the adjustment, make sur that un qual tir pressure is not the cause of steering whe l turning hard in one direction).* Remove all parts, as necessary to gain access to steering tube coupling Remove coupling retaining screw, lockwasher and plain washer from worn shaft Insert manual control valve centering tool C-3445, slotted end first into worm shaft and engage tool with tang on control valve operating rod. *(NOTE–*Two men are required to center the valve). Move pitman arm through its travel from one direction to the other with a torque wrench and a 1 7/16" socket, observing the torque reading The torque should be the same in both directions. Turn adjusting rod as required until an equal torque reading is obtained *(NOTE–*Where gearshaft requires more than 40 ft. lbs to rotate it, or where torque is uneven at any point through the full shaft travel, check for cocked gear shaft cover, dirt in unit, or recirculating balls are defective or improperly installed)

ALL MODELS

PUMP DRIVE BELT ADJUSTMENT: Sufficiently tight to prevent slipping.

HYDRAULIC PRESSURE TEST

Connect Gauge C-3309 in pressure line between pump and hose Refill reservoir to proper level Open valve on gauge, start engine, and run until power steering oil pump reaches operating temperature With engine at normal operating speed, turn shut-off valve on gauge to its closed position *(CAUTION–Do not keep valve closed mor than a few seconds or accelerate engine with valve clos d)* If pressure does not gradually increase to 700 lbs pressure (Chrysler & DeSoto), 600 lbs pressure (Dodge), 750-800 lbs pressure (Plymouth), it is possibly due to fan belt slipping or flow control valve stuck in the open position, or a broken drive coupling If the above pressures are indicated on the gauge, pump is in operating condition

►*TESTING NOTE–*If gauge not available, a fairly accurate way of making the test is as follows. Start engine and turn the wheel to both extreme positions. If the high pressure hose flexes, the pump is in good condition. If hose does not flex, lack of pressure from pump is indicated. Shut off engine and check pump as indicated below.

PUMP CHECK: Remove cover from reservoir start engine and turn steering wheel If oil does not flow through filter, a stuck flow control valve is indicated Shut off engine Remove high pressure hose at pump fitting and insert a ¼" blunt probe against valve plunger If plunger moves inward 3/16-1/4", plunger was stuck and will probably function properly next time Recheck pressure and if found to be below normal (see above), remove flow control valve and clean thoroughly If this does not correct the condition, remove and repair pump assembly If oil does not flow through reservoir filter in above test, check for broken filter or slipping fan belt Check shaft rotation by hand if coupling found to be broken If shaft turns freely, install new couplings on both pump and generator shaft If pump shaft binds when turned by hand, replace both pump and couplings If armature shaft is damaged, replace necessary parts

TROUBLE SHOOTING

HARD STEERING IN BOTH DIRECTIONS: 1) Leak in steering system, pump belt slipping or broken, fluid level low.
2) Steering gear linkage not lubricated, tire pressure too low, bind in steering column or gear, improper front end alignment.
3) Low pump pressure (see Hydraulic Pressure Test above) with particular attention to following: Relief and flow control valve, rotors (not turning or worn), pump body or cover worn.
4) Loss of pressure in power unit (see Hydraulic Pressure Test above).

SMALLER TURNING RADIUS IN ONE DIRECTION: 1) Wheel stops not adjusted properly.

HYDRAULIC LEAKS: 1) Check for leaks at hose adapters, pump body, between gear and worm housings, and gear shaft oil seal.

HARD STEERING IN ONE DIRECTION ONLY: 1) Tire pressure too low.
2) Control valve maladjusted.
3) Bind in steering column or gear, improper front end alignment.

VEHICLE ATTEMPTS TO TURN UNLESS FORCE APPLIED TO HOLD STEERING WHEEL: 1) Tire pressure uneven.
2) Control valve maladjusted.

POOR RECOVERY ON TURNS: 1) Tire pressure too low, improper front end alignment.
2) Gear shaft adjustment too tight, worm bearing adjustment too tight.
3) Balls in worm connector binding, fit too tight.
4) Bind in steering column or gear, bind in steering knuckles.

NOISE IN CHUCK ASSEMBLY: Check belt adjustment Check for vibrating condition set up by control shaft rod Remove unit and install a new valve rod adjusting disc.

HISSING NOISE (NO LOAD): Caused by low oil pressure or improper operation of back pressure valve

HISSING NOISE (RIGHT TURN ONLY): Caused by oil leaking past lower piston rod gear housing seal

HISSING NOISE & LOSS OF OIL THROUGH UPPER HOUSING VENT (LEFT TURN ONLY): Caused by oil leaking past upper piston rod housing head oil seal

CREAKING NOISE ON TURNS: Check for loose gear-to-frame mounting bolts If noise persists after tightening gear-to-frame bolts, install a new equal tooth sector or gear shaft

SNAPPING NOISE: Tighten gear-to-frame mounting bolts Check coupling screw for tightness. Check lower piston rod bushing dowel pin for being too high. Check bushing for seating properly Check lower piston rod for tight fit at piston

CHUCKLE NOISE: Check as follows Steering arm nut loose on gearshaft Loose front wheel bearing Gearshaft adjustment too loose Excessive kingpin endplay Steering tube coupling screw loose Worm bearing preload adjustment too loose Excessive worm shaft endplay

WANDER (STEERING WHEEL FREEPLAY): Check steering wheel freeplay which should not exceed 5/8" If freeplay excessive (without moving steering linkage), check in same manner as for "Chuckle" above, and also check steering linkage and front wheel alignment.

POOR RETURNABILITY (BOTH DIRECTIONS): Check torque required to turn gearshaft from one extreme to the other with torque wrench on steering gear arm nut (linkage disconnected from steering arm). Torque should not exceed 40 ft. lbs., ± 10 lbs. If torque reading not excessive, check wheel alignment and steering linkage. If torque excessive, check steering column jacket bearing. Check gearshaft adjustment. Check worm shaft bearing preload. Check wormshaft for binding in connector.

POOR RETURNABILITY (ONE DIRECTION ONLY): Check tire pressure. Center control valve (see Adjustment). Check gearshaft adjustment.

UNEQUAL STEERING EFFORT: Check control valve adjustment. Check for upper piston rod movement in piston. Check worm shaft connector nut for tightness. Check control valve rod for looseness in valve. Check upper piston rod nut for looseness. Check upper piston rod for being scored at reaction seal retainer. If the above fails to correct unequal steering effort, replace all reaction parts

UNABLE TO MAINTAIN CONTROL VALVE ADJUSTMENT: This may be caused by reaction spacer being too short or too long, or by burrs or out of squareness. Check valve control rod for looseness in disc, or control valve looseness on rod. Upper piston rod nut may be loose, or upper piston rod may be loose in piston

LACK OF ASSIST(ONE DIRECTION): Check for damaged neoprene piston ring. Check for damaged or improperly seated housing head oil seal. Valve rod lower "O" ring may be damaged, or piston rod "O" rings may be damaged.

LACK OF ASSIST (BOTH DIRECTIONS): Check the following. Low tire pressure. Drive belts slipping. Low oil pressure.

LUBRICATION

Since there is no hydraulic connection between the worm and gear housing, the Power Steering has two separate fluid levels. Lubricate as follows

R s rv ir–Check every 1000 miles or every 30 days. Reservoir is mounted at rear of generator. Make sure top of reservoir is absolutely clean. Then, remove cover or filler cap and check oil level. Oil level

CONTINUED ON NEXT PAGE

1954-56 "CO-AXIAL" (C nt.)

should be 1/2" above filter element (if reservoir is tilted, oil level should be 1/2" above highest point of filter element). (NOTE—An oil level mark is stamped on the inside of the reservoir or on the dipstick on type using a filler cap). Replenish as necessary with SAE-10W engine oil. When temperatures are constantly below minus (-) 10° F., drain hydraulic system and refill with SAE-5W engine oil (see Draining and Refilling Hydraulic System below). When temperatures are consistently above minus (-) 10° F., drain the lighter lubricant which may have been added and replace with SAE-10W engine oil. Should the vehicle be operated at extremely high temperatures, it may be necessary to drain and replace the SAE-10W oil with SAE-30 oil for the time it is being operated in these extremely high temperatures. NOTE—When temperature is below minus (-) 10° F. run engine for at least three minutes before putting car in motion or turning steering wheel. Capacity is approximately 2 quarts.

Worm Housing—*(NOTE*—It is not necessary to change oil in worm housing due to temperature). Worm housing does not require periodic checks (unless leakage occurs). However, should the steering gear assembly be removed for any reason, it is recommended it be checked at that time. The oil should be level with the filler plug opening when the gear assembly is in an installed position. Replenish as necessary with SAE-10W engine oil.

DRAINING HYDRAULIC SYSTEM: *(CAUTION—Extreme care should be taken to prevent dirt from entering reservoir while cover or filler cap is removed. To prevent damage to filter element, do not insert sharp objects into reversoir. Do not disturb filter element as periodic changes of this unit are not required).* Disconnect high pressure (small) hose at the gear housing and jack up front end of car sufficiently to raise wheels off floor. Place hose in suitable container. While holding hose in container start engine and allow to idle, turn steering wheel from one extreme to the other until all fluid is forced from unit. *(CAUTION—Do not run engine above idle speed. As soon as fluid starts to show great quantities of air bubbles, stop engine).* Reconnect high pressure hose and refill.

REFILLING HYDRAULIC SYSTEM: Bleed steering gear as follows: Fill reservoir slightly higher than normal. Start engine and run for a short time to circulate oil through hoses. With engine running at idle speed, turn steering wheel back and forth several times from extreme right to left to bleed any remaining air out of system. Check oil level in reservoir. Add oil to reach level mark. Capacity is approximately 2 quarts.

REMOVAL & INSTALLATION
1954 MODELS

REMOVAL: Turn steering wheel to extreme left position to allow for removal of steering gear arm and drag link. Remove horn control ring ornament, cushion and spring. Disconnect horn wire and remove steering wheel nut and wheel. (NOTE—Horn control ring and contact plates will have to be removed if puller C-612 used to remove wheel. See below). Remove steering wheel column jacket bearing spring and spacer (cone shaped). Remove three shroud-to-toe board cover screws, then remove cover from the shroud. Remove accelerator and brake pedal pads and floor mat. Remove steering column jacket toe pad screws (6) and slide toe pad up on jacket assembly. Remove floor pan pedal opening cover screws, remove cover. Remove directional signal indicator, horn and selector lever indicator light wires. Disconnect pressure and return hose from steering gear housing and cap fittings.

Steering Wheel & Horn Button Removal (Using Puller C-612): Disconnect battery, center steering wheel in straight-ahead position. Press down on horn blowing ring ornament and turn counter-clockwise. Lift out ornament retaining spring and pad. Disconnect horn wire from terminal on travel plate and insulator assembly. Remove bushing, travel plate, horn blowing contact ring spring and triangular ground plate. Curl and push horn wire into steering gear tube to make room for steering wheel puller pilot. Remove steering wheel nut. Attach puller Tool C-612 and remove wheel.

►*CAUTION: Fasten ends of hose above level of reservoir to prevent further loss of oil.*

Remove cotter pin and disconnect gearshift control rod from gearshift rod lever. Remove steering gear arm nut, then using tool C-143 with short puller screw SP-2623, remove steering gear arm and drag link. Remove access cover in left front fender shield and remove front lever steering gear assembly to bracket screw, washer and spacer (convex). Note position of wedge between bracket and gear housing. Remove front upper and rear steering gear assembly to bracket screws, washers and spacers (convex) through opening in toe board.

►*CAUTION: Do not lose spacers or wedge.*

Holding jacket and shroud assembly in position, remove the two steering column to instrument panel screws.

►*CAUTION: Steering column to instrument panel screw retaining plate and anti-squeak pad may fall from behind instrument panel when screws are removed.*

Lower jacket and shroud assembly, then remove insulator collar. Slightly push the steering gear column jacket and shroud assembly toward passenger side of vehicle (to permit gear shaft to clear frame bracket) and remove assembly through toe board opening. Place assembly on bench, loosen gear shift rod lever nut and slide lever and spacer (oilite) off gear shift rod. Loosen two nuts on the jacket clamp assembly and slide the jacket and shroud assembly from worm housing. (NOTE—Spring and spring seats (2) may fall from gear shift rod when jacket and shroud assembly is removed). Remove steering gear tube insulator pin, then remove tube and insulator from coupling.

INSTALLATION & ALIGNMENT: Center gear to center of no backlash arc (slot in coupling vertical). Place steering gear tube insulator on tube and position tube and insulator (master serration on steering wheel end of tube in "UP" position) in coupling. Install pin. The horn connector which is located on the jacket assembly is spring loaded. Because of this, the contact point will have to be raised to permit clearance with contact ring on steering tube when jacket and shroud assembly is installed. To accomplish this, bend one end of a piece of wire in the shape of a hook to raise contact point, then bend other end over shroud to hold it in raised position while being installed.

►*CAUTION: In some instances it will be necessary to remove lower half of shroud from jacket assembly and remove horn connector from jacket. Install jacket assembly over steering gear tube, then install horn connector on jacket and reassembl .*

Place gear shift rod spring seats in position in spring (flange portions of seats facing to inside of spring), slide spring and seats over gear shift rod. With horn contact held in raised position by piece of wire and holding spring and seats on gear shift rod, slide jacket and shroud assembly over steering gear tube, guiding gear shift rod into bushing on gear housing. Tighten the two nuts on the jacket clamp assembly and remove piece of wire which was used for holding the horn contact point. Install steering gear assembly through toe board opening pushing column jacket and shroud assembly slightly toward passenger side of vehicle to permit gear shaft to clear frame bracket. Install front upper and rear steering gear housing to bracket spacers (convex), screws and washers through opening in floor pan. Tighten (snugly), then back each one off one turn. Position insulator collar on upper shroud and align the jacket and shroud assembly to instrument panel. Install the two screws, tighten securely. Tighten front upper and rear steering gear housing to bracket screws to 70 ft. lbs. torque (ones that were loosened one turn). Install front lower steering gear housing to bracket spacer (convex), washer and screw **but do not tighten.** Tap wedge into position (over front lower gear to bracket screw) and between bracket and gear housing.

►*CAUTION: Make definitely sure wedge is positioned properly. Tap wedge lightly but do not drive.*

With wedge in position, tighten front lower steering gear housing to bracket screw to 70 ft. lbs. torque. Replace access cover in left front fender shield. Install steering gear arm and drag link, tighten steering gear arm nut to 100-120 ft. lbs. torque. Connect direction signal indicator, horn and selector lever indicator light wires. Install steering column jacket bearing spacer (cone shaped) and spring. Install steering wheel, tighten nut securely (install horn contact plates and control ring, if removed) and connect horn wire. Install horn control spring, cushion and ornament. Check clearance between steering wheel and direction signal housing. If clearance is more or less than 1/8" loosen the two column jacket to instrument panel screws slightly, then, loosen the two nuts on the jacket clamp assembly at top

CONTINUED ON NEXT PAGE

1954-56 "CO-AXIAL" (C nt.)

of worm housing and slide steering column jacket upward or downward to allow for proper clearance. Retighten jacket clamp assembly nuts and column jacket to instrument panel screws. Slide gear shift rod lever spacer (oilite) and lever on rod. Position selector lever in low or reverse, then holding the gear shift rod lever and spacer flush against gear housing, tighten nut.

►*CAUTION Make definitely sure the selector lever remains in the low or reverse position while tightening nut. This procedure necessary to obtain the proper selector lever gate clearances. Check operation by shifting selector lever to all positions.*

Connect gear shift control rod to lever and install cotter pin. Remove the protective caps from fittings in gear housing and connect the pressure and return hoses. Remove reservoir cover or filler cap and fill reservoir to proper level. Start engine and turn steering wheel from one extreme of its travel to the other several times to purge air from system and note operation of steering. If steering seems to operate properly, install the floor pan pedal opening cover and tighten screws securely. Slide the steering column jacket toe pad down into position and install screws (6). Install floor mat, accelerator and brake pedal pads. Place cover on shroud and install screws (3). Recheck oil in reservoir and fill to proper level. Place selector lever pointer in neutral (N) position. Disconnect gear shift control rod at bellcrank located on transmission. Make sure manual control lever (at transmission) is in neutral (N) position (second detent position from rear of vehicle). With selector lever pointer still in neutral (N) position, adjust the gear shift control rod to the required length for a free fit in the lever of the bellcrank, then re-install rod. Operate selector lever through all indicator positions. Road test vehicle.

1955-56 MODELS

REMOVAL: Remove horn ring and ornament from steering wheel. Disconnect horn wire and remove horn ring. Remove steering wheel with puller C-612, and remove signal lever and plate. Loosen steering column to instrument panel bracket. Loosen steering column jacket clamp screws and raise front of car Disengage drag link from pitman arm and pull pitman arm with Tool C-3402. Loosen three gear housing to frame attaching bolts. Remove floor mat retaining plate and rubber dust pad. Disconnect pressure and return hoses and drain gear assembly by slowly rotating steering wheel until all oil is expelled from unit. Fasten disconnected ends of hoses above oil level in reservoir to prevent loss of oil and cap hose ends to prevent dirt entering. Remove gear housing to frame bolts and alignment wedge and remove gear assembly from lower side of car.

Steering Wheel & Horn Button Removal (Using Puller C-612): *See 1954 Removal & Installation.*

INSTALLATION & ALIGNMENT: Install steering gear assembly from under the car and up through the dash panel into the jacket Install housing to frame attaching bolts, flat washers, swivel washers and nuts, but do not tighten (swivel washers permit alignment to dash) Slide steering column jacket down over worm housing. Install turn signal lever, being sure column jacket does not restrict lever Tighten jacket to steering gear housing clamp. Connect turn signal wires. Install steering column to instrument panel bracket and install steering wheel If clearance between steering column jacket and steering wheel is less than 1/8", adjust steering column jacket to provide proper clearance. Install dust pads and retaining plates. Tighten front upper and lower gear housing to frame attaching bolts to 20 ft lbs. Install wedge over rear bolt between housing and frame, so that tapered surfaces match, tapping it lightly in place. Tighten three attaching bolts to 70 ft. lbs Install horn ring and horn wire in steering wheel and install horn ring ornament Connect hoses from steering gear to hydraulic pump

STEERING GEAR OVERHAUL

►*CAUTION* Cleanliness in executing all overhaul procedures cannot be over-emphasized. Unit should be thoroughly cleaned in a suitable solvent when removed from vehicle. When disassembling, each part should be placed in the solvent, washed, then dried with compressed air. Careful handling of parts is necessary to avoid occurrence of nicks and burrs. Crocus cloth may be used to remove small nicks and burrs provided it is used carefully. When used on valve spool, use extreme care not to round off sharp edge portion. (NOTE–Sharp edge portion helps prevent dirt and foreign matter from getting between the valve and bore, thus reducing possibilities of sticking). Remove and discard all "O" ring seals, and seals, using new ones lubricated with Lubriplate when reassembling.

DISASSEMBLY & INSPECTION: Proceed as follows.

Removal of Worm Housing from Gear Housing: 1) Drain lower portion of steering gear through pressure and return connections, by turning steering tube coupling from one extreme of travel to the other. Using a 3/16" allen wrench, remove worm housing filler plug and drain worm (upper) housing.

2) Attach holding fixture C-3323 to unit and place in vise.

3) Remove tube coupling screw, lockwasher, and washer from center of coupling. Using tool C-3392, remove coupling from worm shaft. (NOTE–Tool C-3112 may also be used to remove coupling. However, to accomplish this, it will be necessary to cut one adapter plate SP-1409 in half and using these two parts instead of the two plates).

4) Using extreme care and a screwdriver, remove worm housing oil seal from housing and worm shaft.

5) Unlock bearing adjusting nut by bending tang of lockwasher. (NOTE–Only one tang locks nut in position). Place tool C-3320 over worm shaft followed by C-3319. Holding the worm stationary remove worm bearing adjusting nut, lockwasher, and thrust washer (NOTE–Worm bearing adjusting nut tapered on one side).

6) Remove worm outer bearing race and bearing roller from worm. Inspect bearing roller for wear or pitting.

7) Remove three worm to gear housing screws and belleville washers (Note installed position of washers on screws. Concave side of washers fit against housing). Remove worm housing. (NOTE–It may be necessary to tap housing lightly due to interference of "O" ring seal between housing head and housing

8) Remove inner bearing race from worm shaft and inspect for wear or pits.

9) Remove lower bearing roller from housing. Inspect bearing roller and the upper and lower bearing cups in housing. **Do not remove bearing cups unless inspection reveals it is necessary to do so.** To remove upper and lower bearing cups use tool C-3322.

Removal of Worm Connector: 1) Remove housing head "O" ring and discard (Use new rings when assembling). Unlock worm connector nut lock and slide lock back sufficiently to loosen worm connector nut.

2) With tool C-3321 attached to worm connector, remove connector nut using tool C-3326 (NOTE -It may be necessary to rotate steering gear shaft to raise worm connector and permit installation of tool C-3326).

3) Slide worm connector assembly from valve control spacer.

Disassembly of Worm Connector–*(CAUTION–Do not bottom worm shaft in the outward direction upon disassembly or assembly. Bottoming the worm shaft may damage the ball guides and cause a tight and rough operating worm).*

1) Remove the two worm connector ball guide clamp screws and lockwashers. Remove guide clamp.

2) Using care not to lose any of the worm balls, carefully remove the ball guide from the worm connector. *CAUTION–Worm balls are a select fit with each other. If any of them are damaged and require replacing, it is recommended that a complete set (40) be installed.*

3) Turn worm connector over and carefully thread the remaining worm balls out of the worm connector by turning worm in and out. Count the worm balls which were removed so that the same number can be installed. There should be (40).

4) Remove worm from connector, slide connector nut lock from connector.

5) Inspect guide rails on connector for nicks and burrs.

Removal of Piston & Rods from Gear Housing: 1) Remove pressure and return hose adapters and copper gaskets.

2) Remove steering gear shaft oil seal lock ring (circular section), then, using tool C-3350, remove steering gear shaft oil seal.

3) Remove lock nut from shaft adjusting screw.

4) Remove three cover screws, belleville washers, and neoprene seals.

5) Remove steering gear shaft cover from housing by turning adjusting screw in. Remove cover gasket and discard (use new gasket when reassembling)

6) Using steering arm (if necessary) align steering gear shaft with cover opening in housing. Remove steering gear shaft assembly from gear housing by using a fiber hammer and tapping lightly.

7) Using tool C-3229, remove adjusting screw retaining snap ring. Remove adjusting screw, thrust washer

CONTINUED ON NEXT PAGE

1954-56 "CO-AXIAL" (C nt.)

and washer from steering gear shaft. Remove adjusting screw "O" ring.

8) Inspect needle bearings in cover for broken needles and inspect bearing surface on shaft for scoring or pitting. *CAUTION–Do not remove bearing from cover as bearing and cover are serviced as an assembly. Inspect condition of teeth on shaft.*

9) Using C-760 pliers remove gear housing cover snap ring (tapered) at bottom of housing, remove housing cover. Remove "O" ring from housing and discard (use new ring on reassembly).

10) Place a suitable container under the assembly (to catch trapped oil), then slide piston assembly and rods from gear housing. *CAUTION–Use extreme care in handling so as not to damage the sealing surfaces on housing head.*

Disassembly of Piston & Rods– 1) Remove valve rod adjusting disc from valve rod, slide valve rod adjusting disc retainer from upper piston rod, remove upper piston rod nut lock cap.

2) Using tool C-3328, remove upper piston rod nut. *CAUTION–Support upper piston rod on block of wood to help prevent damaging housing head when removing nut. Assembly may also be supported by wrapping several layers of masking tape around the rack teeth and sealing surfaces of lower piston rod and clamping it in a vise equipped with protective jaws.*

3) Slide valve control spacer, seal assembly, upper and lower valve control spacer seal retainers from upper piston rod. Remove spacer retainers from spacer, slide seal assembly from valve control spacer.

4) Remove worm connector nut from upper piston rod, slide housing head off upper piston rod. Remove housing head "O" ring and discard (use new ring on reassembly).

5) Using suitable drift, remove upper piston rod seal (lip type) from housing head.

6) Remove two backup (steel) and "D" type (neoprene) piston rings from piston.

7) Using C-760 pliers, remove lower piston rod snap ring and slide lower piston rod from piston.

8) Using care not to bend valve adjusting rod, slide valve assembly from piston assembly.

9) Using a 1/4" punch, drive piston pin into upper piston rod, then using C-760 pliers, remove upper piston rod snap ring. **Note position and construction of snap ring.**

10) Remove upper piston rod from piston. Using a wire hook, remove piston pin and "O" ring from piston rod, discard "O" ring (use new ring on reassembly). Make sure oil passage is open. Inspect sealing surface on piston rod for scoring. Remove the two valve rod "O" rings (one in each end of upper piston rod) remove upper piston rod "O" ring (discard rings, use new rings on reassembly).

11) Remove lower piston rod "O" ring (discard and use new ring on reassembly). Inspect rack teeth and sealing surfaces on lower piston rod. Make sure oil return hole is open.

12) Inspect piston for nicks and burrs. Make sure all oil passages are open and free of dirt.

Removal of Relief Valve Assembly: Thread a ¼"-28 bolt into threads provided in plug. Clamp bolt in vise and pull on lower piston rod to remove plug. If end plug is seized in rod, tap on retaining flange at lower end of piston with a fibre hammer. Inspect piston for nicks and burrs. Make sure all passages are open and free from dirt.

Disassembly of Steering Gear Housing: 1) Using C-3128 pliers, remove piston rod bearing support pin snap ring. Slide bearing support pin out of gear housing and remove roller support assembly. Inspect roller and needle bearings. Inspect bearing support pin for wear or scoring. Remove two bearing support pin "O" rings located in each side of gear housing and discard (use new rings on reassembly).

2) Inspect steering gear shaft needle bearing in gear housing for broken or rough needles. **Do not remove bearing unless inspection reveals it is necessary to do so.**

3) Using driver C-3333, drive steering gear housing shaft needle bearing from inside gear housing. Remove lower piston rod seal (lip type) from housing.

REASSEMBLY & ADJUSTMENT:–Proceed as follows:

Steering Gear Housing: 1) Remove garter spring from a **new** piston rod seal (to prevent being damaged by tool when installing) and position seal over driver C-3331 (position seal so lip will be facing up or to inside of cylinder when installed). Insert seal aligning pilot of tool in end of driver and drive lower piston rod seal into position in gear housing. *CAUTION–Replace garter spring in piston rod seal.*

2) Using driver C-3333, install housing shaft needle bearing assembly into gear housing until driver marking on driver is even with side of housing. *CAUTION–Always drive on letter side of bearing, otherwise damage to bearing may result.*

3) Lubricate the two **new** piston rod bearing support pin "O" rings with Lubriplate and install into gear housing at outer edge of bearing support pin holes. Make sure they are properly seated in housing.

4) Start piston rod bearing support pin through hole in cover side of housing. Place roller support assembly into position in housing and push support pin through roller assembly until it protrudes sufficiently on opposite side of housing to install snap ring. Using C-3128 pliers, install snap ring, making sure it is properly seated.

Piston & Rods 1) Insert relief valve spring followed by plunger into valve body and insert assembly (milled end first) into lower piston rod. Press end plug into lower piston sufficiently to seat against relief valve body (*NOTE*–A suitable adapter will be required to press end plug into place. Otherwise, damage to rod will result. If plug is not pressed in far enough to properly seat against the valve body, it will produce a rattling or clattering sound when hydraulic pressure is applied. If the plug is pressed in too tightly, it will cause relief valve ports in valve body to collapse, restricting the plunger and creating high back pressure, resulting in lack of steering assistance). Lubricate the two **new** valve rod "O" rings with Lubriplate and install one in each end of piston rod. Make sure the rings are seated properly.

2) Lubricate the two **new** large "O" rings with Lubriplate and install one on each upper and lower piston rod. Make sure rings seat properly in ring grooves.

3) Install lower piston rod (with rack) into end of piston assembly opposite piston pin hole and using C-760 pliers, install snap ring. *CAUTION–When installing snap ring, minimum gap opening of 25/64" is specified. Care should be exercised to locate the gap at the middle ports of the five ports without obstructing the middle port or adjacent ports with snap ring ends. Make sure snap ring is seated properly.*

4) Lubricate valve assembly with Lubriplate and slide into piston assembly. Using care not to damage "O" rings, slide upper piston rod over valve rod, aligning piston pin hole in the piston assembly with the hole in the upper piston rod.

5) Lubricate **new** piston pin "O" ring with Lubriplate and install on piston pin. With piston pin holes aligned in both the piston and upper piston rod, position piston pin (tapered end first) in piston. Using a 1/4" punch and hammer, tap lightly until piston pin is flush with bottom of piston pin groove. Using C-760 pliers, install upper piston rod snap ring. *See CAUTION under 3) above.*

6) Remove garter spring from a **new** upper piston rod seal (to prevent being damaged when installing seal) and position seal on driver C-3331 (lip of seal facing tool). Insert seal aligning pilot of tool in end of driver. Drive upper piston rod seal (lip of seal out) into position in housing head. Replace garter spring and lubricate seal with Lubriplate. Install housing head assembly (sealing lip first) onto upper piston rod. *CAUTION– Use extreme care to protect sealing surfaces on housing head.*

7) Slide connector nut onto upper piston rod with open threaded end away from piston.

8) Lubricate the valve control spacer seal (new) with Lubriplate and install in center of valve control spacer. *CAUTION–Should it be necessary to replace the valve control spacer or upper piston rod for any reason, always select a spacer to match. The length of the valve control spacer selected, must be identical to the distance between the seat of the valve control spacer seal retainer and the seated upper piston rod nut.*

9) Slide one of the valve control spacer retainers (large diameter first) on upper piston rod. Lubricate with Lubriplate. Place tool C-3329 over threaded end of upper piston rod. Lubricate the valve control spacer retainer with Lubriplate and place into posi-

CONTINUED ON NEXT PAGE

1954-56 "CO-AXIAL" (Cont.)

tion (small diameter first) so it nests in valve control spacer. Slide spacer, seal and retainer over tool C-3329 and into position on piston rod, remove tool.

10) Install upper piston rod nut and using tool C-3328, tighten securely (25-30 ft. lbs. torque). Lock in place using piston rod nut lock by tapping outer diameter of lock into nut recess.

11) Slide valve rod adjusting disc retainer (largest diameter first) over end of upper piston rod. Thread valve rod disc (extended lock thread section being outward) onto valve rod until approximately three threads show (for aid in later adjustment).

12) Place lock ring on worm connector (tang of ring toward threaded end). Slide worm connector (less ball bearings and worm shaft) over valve control spacer, then screw worm connector nut onto connector. Hold worm connector with tool C-3321, then using tool C-3326, tighten nut. Stake ring with punch.

13) Lubricate the two "D" type (neoprene) piston rings with Lubriplate and install on piston. To aid in installation of rings, first slide rings over ring lands and to center of piston with lips facing away from each other. Next, slide rings into position in ring lands. Install backup (steel) rings one on each end of the piston, in extreme position from the center of the piston.

Installation of Piston & Rod Assembly into Gear Housing: 1) Lubricate lower piston rod, teeth of rack and tool C-3391 with Lubriplate, then position tool in teeth of rack.

2) Place ring compressing tool C-3344 on gear housing. Position piston and rod assembly so teeth on rack are 180° from roller support assembly and install into gear housing. *CAUTION–Use extreme care when performing this operation so as not to damage gear housing oil seal or piston rings. Do not use screwdriver to compress piston rings. To further aid in installation, piston and cylinder may be lubricated with Lubriplate. If rack is not positioned properly when it is installed, it may be corrected by rotating the lower piston rod with a screwdriver through opening in end of gear housing.* Remove ring compressing tool C-3344, and tool C-3391 from teeth of rack through opening in gear housing.

3) Lubricate large new "O" ring with Lubriplate and install on the side of housing head which faces piston assembly.

4) Carefully slide tool C-3324 (dummy housing) over worm connector and secure housing head to gear housing, tighten the three screws to 25-30 ft. lbs torque.

5) Install thrust washer on gear shaft adjusting screw and position tool C-3401 over thread of screw. Lubricate adjusting screw "O" ring with Lubriplate and slide over tool and into position on adjusting screw. Remove tool and insert adjusting screw thrust washer into gear end of steering gear shaft. Insert adjusting screw assembly into gear shaft and lock into position by inserting internal snap ring. Use C-3229 pliers and make sure snap ring is properly seated. Screw shaft adjusting screw with gear attached into the gear shaft cover assembly as far as possible.

6) Center the second tooth of the rack over center line of piston rod bearing support pin.

7) Lubricate a **new** gear shaft cover gasket with Lubriplate (to help hold it in place) and position it on cover of housing.

8) Center the center line of the middle tooth on gear shaft with second tooth **space** from end of rack. Insert gear shaft assembly with cover attached into gear housing, tap lightly into position. Place belleville washers and new seals on screws and secure cover to gear housing. Draw down evenly and tighten to 25-30 ft. lbs. torque.

9) Lubricate **new** gear housing cover "O" ring with Lubriplate and install on housing cover. Push assembly (seal end first) into housing and install snap ring.

10) Before attempting to install a **new** seal, thoroughly clean sealing surface on the gear shaft and counterbore of steering gear housing. Lubricate a **new** steering gear shaft oil seal with Lubriplate and place (lip of seal down) on a piece of clean paper. **Carefully** install tapered end of sleeve (part of tool C-3350) in seal and slide seal back approximately 1/4" on sleeve. Install this assembly (lip of seal toward housing) over steering gear shaft until seal contacts counterbore in housing. Push seal into position by installing adapter over sleeve, and installing coupling nut on shaft threads until shoulder of adapter contacts housing. Remove nut and adapter. Wrap a new piece of friction tape around sleeve to provide a firm grip and with a turning motion, remove sleeve from seal and gear shaft. Seal is then positioned properly. Install oil seal lock ring (circular section) and make sure it is properly seated. Install gear shaft adjusting screw lock nut, but do not tighten.

11) Secure steering gear arm from stock or remove one from vehicle. Install steering gear arm, lockwasher and nut, and tighten nut from 30-40 ft. lbs. torque (low torque reading for checking purposes only). Work steering arm back and forth forcing piston to its full length of travel. Adjust gear, if necessary, into a backlash position, then tighten lock nut.

CAUTION–This adjustment necessary before hydraulically centering gear assembly and is not to be considered a final adjustment.

12) Proceed as indicated under steps **7)** through **13),** Centering Control Valve, and Required Re-Assembly Operations After Adjusting Control Valve, outlined under "Control Valve" in ADJUSTMENT section above.

13) For final gear adjustment proceed as outlined under "Centering Steering Tube Coupling & Adjusting Backlash Between Gear Shaft & Rack Teeth" in ADJUSTMENT section above.

HYDRAULIC PUMP

►*PUMP COUPLING NOTE:* Two different types of pump drive coupling have been used and special Pump and Generator must be used with each type coupling (special shaft used with each coupling).

1) Rubber Insulated Coupling–Oilite coupling flanges are pressed on generator and pump shafts and retained by special "thread locking" type capscrew and **plain** washer (lockwashers should not be used with these screws). A rubber insulator and insulator sleeve are installed between the coupling flanges to transmit the drive.

2) Metal Tongue Coupling–Tongue-and-slot type metal coupling. Coupling members are retained on shaft ends by a retaining ring and slide off after ring removed.

PUMP OVERHAUL: *See "Chrysler, DeSoto, Dodge, Plymouth (Single Motor)' under "Power Steering Pumps".*

CHRYSLER. DE SOTO, DODGE, PLYMOUTH 1957 "CO-AXIAL"

Chrysler, Imperial, De Soto, Dodge, Plymouth (1957)

►CHANGES, CAUTIONS, CORRECTIONS

►*1957 CHRYSLER NOISY FAN BELT OPERATION CORRECTION:* This noisy condition may be caused by a stuck flow control valve in the power steering pump. Check pump pressure with engine operating at 1200 RPM. If pressure is greater than 950 lbs., replace the pump. DO NOT attempt to recondition the pump.

►*DODGE SELF-STEERING TO RIGHT CORRECTION* Adjust power steering gear control valve. If condition is not corrected, it may be caused by fluid leaking by the valve adjusting rod upper "O" ring seal or the reaction seal. See "Overhaul" below for correction.

►*1957 DESOTO POWER STEERING PUMP PRODUCTION CHANGE:* A new power steering pump, Part No. 182-6158, identified by the convex shape of the pulley, replaces Part No. 1730892, beginning with Car Serial Nos. S-25-55337661, S-26-50399739, S-27-58003300. The new pulley used with the later type pump is not interchangeable with the earlier pump. The later type pump will be furnished for service replacement.

►*PUMP PULLEY LOOSENESS CORRECTION:* If the pump pulley is loose and pulley attaching capscrew is tight, replace the washer with Part No. 567331.

DESCRIPTION: Design is similar to power steering gear used on 1954-56 models, however, changes have been made in the lower housing, power piston rings, and in worm shaft bearing assemblies.

ADJUSTMENT: *(NOTE - Three adjustments as follows, can be made without removing steering gear from the car. Make adjustments in the sequence indicated).* Remove steering wheel (see below), steering column jacket and tube. Remove tube coupling bolt and washer from center of coupling, then using Tool C-3392, remove coupling from worm shaft and remove worm housing seal. Remove steering drag link from steering gear arm. Back off gear lash adjusting screw until lash is maximum. Proceed as follows:

Worm Shaft Bearing Adjustment: Slide Tool C-3320A over adjusting nut, and Tool C-3319 on splines of worm shaft with sufficient space between tools to lift Tool C-3320A off the adjusting nut. Turn steering gear to full left and hold in this position with a ft. lb. torque wrench. Attach torque wrench C-3380 to Tool C-3320A in an "in-line" position *(NOTE - Tool C-3380 is a special inch-pound torque wrench having a special extension adapter).* While holding 5 ft. lbs. tension (toward left), loosen nut with small wrench and then adjust to exactly 5 inch-pounds on Tool C-3380. Remove tools with caution to prevent moving adjusting nut and crimp ring section of adjusting nut into keyway in worm shaft. Install worm housing seal.

Piston Valve Adjustment: Start engine and run at medium idle speed. Allow gear to reach normal operating temperature. Attach a small tap handle to flat on end of Tool C-3445, then insert tool through the worm shaft over end of piston valve rod. With a ft. lb. torque wrench on the steering arm nut, read tension while turning steering gear to full right and left. Wrench movement should be smooth. Turn piston valve in the direction necessary to obtain the same torque reading in both directions. Torque reading must be equal and under 40 ft. lbs. If torque reading is equal at less than 25 ft. lbs., a more accurate reading can be made using a 300 inch-pound torque wrench.

Gear Lash Adjustment: With engine running and steering gear at normal operating temperature, turn steering gear to straight ahead position. Using a very light finger tip touch at end of steering gear arm turn gear shaft adjusting screw clockwise until all gear lash has been eliminated. **Turn adjusting screw ¾ turn tighter (clockwise) and tighten locknut.** Stop engine and install worm housing oil seal (with lip of seal down). With gear still in the straight ahead position, install coupling on worm shaft with slot in an up-and-down position. Install drag link on steering gear arm, then install steering tube, steering wheel, etc.

Pump Drive Belt Adjustment: Adjust as follows:

Chrysler & Imperial (Early Cars) - Loosen pivot and adjusting slot bolts, then using a lever between pump and engine, tighten belts so that deflection on one of the belts is 3/8" with a 5 lb. force applied midway between fan and pump pulleys. Tighten pivot bolt first, then tighten adjusting slot bolt.

Chrysler & Imperial (Later Cars) - A square hole is provided in pump bracket to permit using a torque wrench for adjusting belt tension. Loosen pivot and adjusting slot bolts, then insert torque wrench in square hole and apply a 90 lb. torque. Tighten pivot bolt first, then tighten adjusting slot bolt.

DeSoto.- 3/16" belt deflection with a 5 lb. force applied midway between fan and pump pulleys.

Dodge - 1/8" (new belt), ¼" (used belt) deflection of belt measured midway between crankshaft and pump pulleys.

Plymouth V8 - A 20 ft. lb. torque should be required to slip pump pulley on belt with torque wrench applied to pump pulley attaching bolt.

LUBRICATION: Check fluid level in reservoir every 1000 miles or every 30 day. Maintain level of fluid to "Full" mark on reservoir using Automatic Transmission Fluid Type "A".

►*WORM HOUSING FLUID LEVEL NOTE:* It is not necessary to check fluid level in worm housing at regular intervals. When gear is removed for overhaul or for other reasons, fill worm housing to level of filler plug hole (with gear in normal installed position).

DRAINING HYDRAULIC SYSTEM: *(CAUTION–Extreme care should be taken to prevent dirt from entering reservoir while cover or filler cap is removed. To prevent damage to filter element, do not insert sharp objects into reservoir. Do not disturb filter element as periodic changes of this unit are not required).* Disconnect high pressure (small) hose at the gear housing and jack up front end of car sufficiently to raise wheels off floor. Place hose in suitable container. While holding hose in container start engine and allow to idle, turn steering wheel from one extreme to the other until all fluid is forced from unit. *(CAUTION–Do not run engine above idle speed. As soon as fluid starts to show great quantities of air bubbles, stop engine).* Reconnect high pressure hose and refill.

REFILLING HYDRAULIC SYSTEM: Bleed steering gear as follows: Fill reservoir slightly higher than normal. Start engine and run for a short time to circulate oil through hoses. With engine running at idle speed, turn steering wheel back and forth several times from extreme right to left to bleed any remaining air out of system. Check oil level in reservoir. Add oil to reach level mark. Capacity is approximately 2 quarts.

TROUBLE SHOOTING

HARD STEERING IN BOTH DIRECTIONS: 1) Leak in steering system, pump belt slipping or broken, fluid level low.
2) Steering gear linkage not lubricated, tire pressure too low, bind in steering column or gear, improper front end alignment.
3) Low pump pressure (see Hydraulic Pressure Test above) with particular attention to following: Relief and flow control valve, rotors (not turning or worn), pump body or cover worn.
4) Loss of pressure in power unit (see Hydraulic Pressure Test above).

SMALLER TURNING RADIUS IN ONE DIRECTION: 1) Wheel stops not adjusted properly.

HYDRAULIC LEAKS: 1) Check for leaks at hose adapters, pump body, between gear and worm housings, and gear shaft oil seal.

HARD STEERING IN ONE DIRECTION ONLY: 1) Tire pressure too low.
2) Control valve maladjusted.
3) Bind in steering column or gear, improper front end alignment.

VEHICLE ATTEMPTS TO TURN UNLESS FORCE APPLIED TO HOLD STEERING WHEEL: 1) Tire pressure uneven.
2) Control valve maladjusted.

POOR RECOVERY ON TURNS: 1) Tire pressure too low, improper front end alignment.
2) Gear shaft adjustment too tight, worm bearing adjustment too tight.
3) Balls in worm connector binding, fit too tight.
4) Bind in steering column or gear, bind in steering knuckles.

NOISE IN CHUCK ASSEMBLY: Check belt adjustment. Check for vibrating condition set up by control shaft rod. Remove unit and install a new valve rod adjusting disc.

HISSING NOISE (NO LOAD): Caused by low oil pressure or improper operation of back pressure valve.

CONTINUED ON NEXT PAGE

1957 "CO-AXIAL" (Cont.)

HISSING NOISE (RIGHT TURN ONLY): Caused by oil leaking past lower piston rod gear housing seal.

HISSING NOISE & LOSS OF OIL THROUGH UPPER HOUSING VENT (LEFT TURN ONLY): Caused by oil leaking past upper piston rod housing head oil seal.

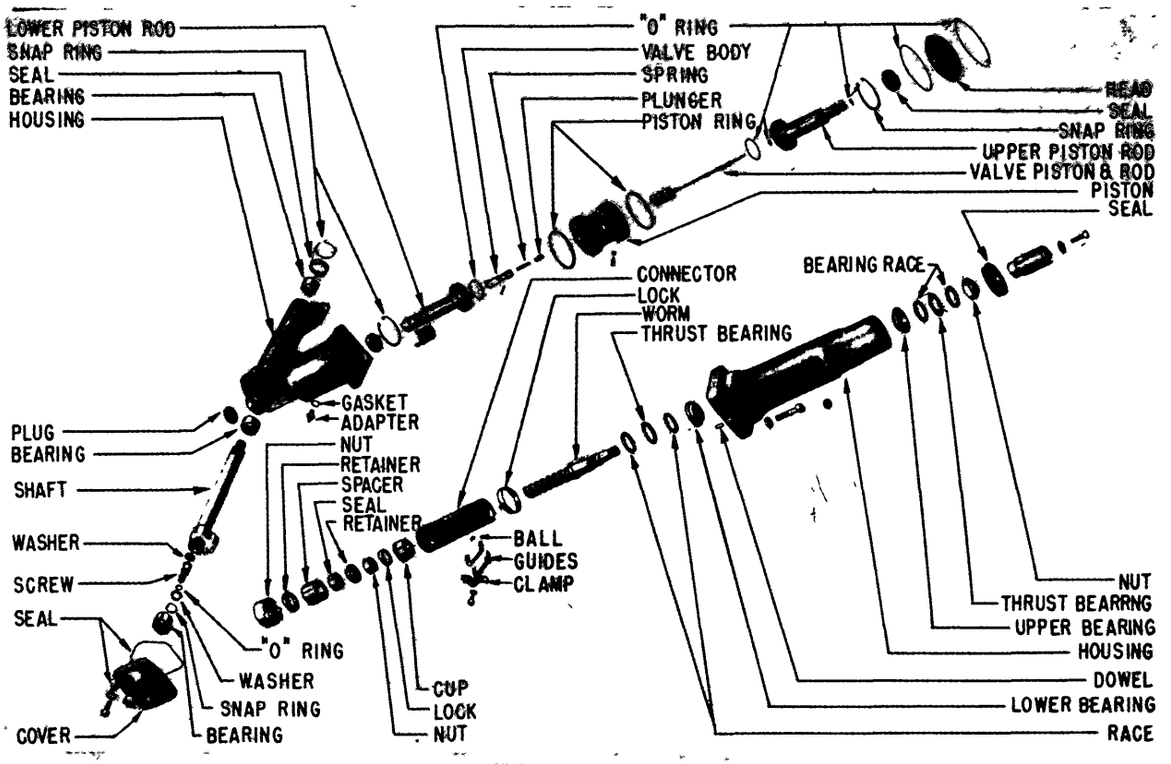
CREAKING NOISE ON TURNS: Check for loose gear-to-frame mounting bolts. If noise persists after tightening gear-to-frame bolts, install a new equal tooth sector or gear shaft.

SNAPPING NOISE: Tighten gear-to-frame mounting bolts. Check coupling screw for tightness. Check lower piston rod bushing dowel pin for being too high. Check bushing for seating properly. Check lower piston rod for tight fit at piston.

CHUCKLE NOISE: Check as follows: Steering arm nut loose on gearshaft. Loose front wheel bearing. Gearshaft adjustment too loose. Excessive kingpin endplay. Steering tube coupling screw loose. Worm bearing preload adjustment too loose. Excessive worm shaft endplay.

WANDER (STEERING WHEEL FREEPLAY): Check steering wheel freeplay which should not exceed 5/8". If freeplay excessive (without moving steering linkage), check in same manner as for "Chuckle" above, and also check steering linkage and front wheel alignment.

POOR RETURNABILITY (BOTH DIRECTIONS): Check torque required to turn gearshaft from one extreme to the other with torque wrench on steering gear arm nut (linkage disconnected from steering arm). Torque should not exceed 40 ft. lbs., ± 10 lbs. If torque reading not excessive, check wheel alignment and steering linkage. If torque excessive, check steering column jacket bearing. Check gearshaft adjustment. Check worm shaft bearing preload. Check wormshaft for binding in connector.



POOR RETURNABILITY (ONE DIRECTION ONLY): Check tire pressure. Center control valve (see Adjustment). Check gearshaft adjustment.

UNEQUAL STEERING EFFORT: Check control valve adjustment. Check for upper piston rod movement in piston. Check worm shaft connector nut for tightness. Check control valve rod for looseness in valve. Check upper piston rod nut for looseness. Check upper piston rod for being scored at reaction seal retainer. If the above fails to correct unequal steering effort, replace all reaction parts.

UNABLE TO MAINTAIN CONTROL VALVE ADJUSTMENT: This may be caused by reaction spacer being too short or too long, or by burrs or out of squareness. Check valve control rod for looseness in disc, or control valve looseness on rod. Upper piston rod nut may be loose, or upper piston rod may be loose in piston.

LACK OF ASSIST(ONE DIRECTION): Check for damaged neoprene piston ring. Check for damaged or improperly seated housing head oil seal. Valve rod lower "O" ring or piston rod "O" rings may be damaged.

LACK OF ASSIST (BOTH DIRECTIONS): Check the following: Low tire pressure. Drive belts slipping. Low oil pressure.

CHRYSLER, DESOTO, DODGE, PLYMOUTH "CO-AXIAL" POWER STEERING GEAR

STEERING WHEEL & HORN BUTTON REMOVAL & INSTALLATION

HORN BUTTON REMOVAL & INSTALLATION: Chrysler - Disconnect battery. Turn horn blowing ring ornament counterclockwise and remove ornament. Disconnect wire from terminal. Remove three screws and three bushings and remove horn ring. Remove horn blowing contact ring switch from steering wheel hub. Reverse removal procedure to install.

Imperial: Remove two screws and washers from underside of steering wheel spokes and remove horn ring and cushion assembly. Disconnect horn wire. Remove four screws and bushings and remove horn blowing ring retainer and horn switch. Remove four screws and washers and remove ground plate from steering wheel. Reverse removal procedure to install.

DeSoto: Disconnect battery ground cable, then remove horn ring ornament by turning it counterclockwise. Disconnect horn wire at stationary plate and remove plate. Remove horn ring mounting base attaching screws and remove horn ring. Reverse removal procedure to install.

Dodge: Remove two screws from horn ring ornament and remove ornament from steering wheel. Disconnect horn wire, then remove three horn ring screws and remove horn ring. Reverse removal procedure to install.

Plymouth: Disconnect battery, then remove the two screws on underside of medallion and remove medallion. Disconnect horn wire from terminal on travel plate and insulator, then remove horn ring, travel plate and insulator assembly, contact spring plate and ground plate. Reverse removal procedure to install.

STEERING WHEEL REMOVAL: Chrysler, Imperial, & DeSoto - Remove horn ring assembly (see above), then loosen steering wheel nut three full turns and attach Puller, Tool C-3428. Remove wheel from serrations, and remove tool, nut and steering wheel. To install steering wheel, place both front wheels in the straight ahead position, then install steering wheel and nut and tighten nut to 40 ft. lbs. *(NOTE* - Check to make sure cancelling dogs on steering wheel actuate the directional switch).

Dodge & Plymouth - Remove horn ring assembly (see above), then install Puller, Tool C-612 and remove steering wheel. When installing steering wheel make sure that master serrations are in alignment and that directional signal cancelling cam on bottom of wheel is inserted between switch levers (if so equipped).

STEERING GEAR REMOVAL & INSTALLATION

REMOVAL: Chrysler & Imperial - Remove horn ring assembly and steering wheel (see above). On Chrysler, remove two screws and bracket clamp securing steering column jacket at instrument panel. Disconnect directional indicator wires and horn wire at connectors

CONTINUED ON NEXT PAGE

1957 "CO-AXIAL" (C nt.)

below instrument panel. Loosen two screws and nuts at steering gear housing jacket at lower clamp. Remove column jacket by carefully turning assembly clockwise and pulling upward. On Imperial, remove cover plate, then remove turn signal and bracket. Remove shield, Loosen two clamp screws at lower clamp and loosen three gear housing to frame attaching bolts and remove jacket cover. On Chrysler & Imperial, remove pin and disconnect steering tube from coupling. Remove floor mat retaining plate, then remove dust pad and floor panel opening cover. Disengage drag link from steering gear arm and pull steering gear arm with Tool C-3402. Disconnect pressure and return hoses. Cap fittings at steering gear and raise hoses above oil level in reservoir to prevent oil loss. Cap ends of hoses. Disconnect stop light switch wires from brake master cylinder, then disconnect brake booster reservoir from fender side shield and move aside. Remove gear housing-to-frame attaching bolts and alignment wedge. Remove gear assembly by sliding unit forward and out of engine compartment.

Desoto, Dodge, & Plymouth-Remove horn ring assembly and steering wheel (see above), then remove front seat cushion. Raise front of car and remove pitman arm with Tool C-3402 and loosen steering gear housing to frame bolts. Remove jacket tube support bracket at dash panel. On DeSoto, disconnect shroud retaining spring from gear housing shroud and remove shroud and rubber shield at firewall. Remove floor opening panel, then remove jacket tube. On Dodge & Plymouth, remove shroud at upper end of steering column, then pull jacket from steering column shaft. Remove floor mat retaining plate, dust pad and access cover. Disconnect pressure and return hoses and cap ends of hoses and fittings on steering gear. Remove steering gear attaching bolts, then lift gear assembly up through opening in floor pan.

INSTALLATION: All Models - Reverse removal procedure and note the following: Tighten front upper and lower gear housing to frame attaching bolts to 20 ft. lbs. Install wedge over rear bolt between housing and frame, tapping lightly in place. Tighten the three attaching bolts to 50 ft. lbs. (Chrysler, Imperial, & DeSoto), 70 ft. lbs. (Dodge & Plymouth). Check alignment of steering column on DeSoto, Dodge, & Plymouth to make usre there is no bind at instrument panel bracket. If necessary, install shims between frame and gear housing to eliminate any binding condition.

OVERHAUL

►*1957 DODGE SELF-STEERING TO RIGHT SIDE CORRECTION:* If adjusting the control valve does not correct this condition, remove the valve adjusting cup to determine if fluid has leaked by the valve adjusting rod upper "0" ring seal or the reaction seal, correct by replacing the seals, then check to see if there is a port in the adjusting cup. If there is no hole, drill a 3/16" opening in disc midway between nylon inserted nut and rim of disc.

►*DISASSEMBLY & REASSEMBLY NOTE: Clean st ering gear with s lv nt before disassembly. During diass mbly, cl an each part and dry with compressed air. Install all n w "0" ring s als.*

DISASSEMBLY: (W rm H using R m val) - Drain upper and lower housing, then attach holding fixture Tool C-3323 and install in a vise. Remove coupling attaching bolt and drive coupling from shaft with Tool C-3392. Gently pry worm housing seal from end of worm shaft, then pry locking collar portion of bearing adjusting nut out of keyway in worm shaft. Install Tool C-3320A on adjusting nut and Tool C-3319 over end of shaft, engaging the serrations. Hold worm shaft steady and loosen bearing adjusting nut. Remove tools and adjusting nut *(NOTE - A new nut must be used at reassembly).* Slide outer bearing race, thrust bearing inner race and spacer out of housing. Remove worm housing attaching bolts, then slide worm housing away from gear housing exposing the worm connector. Remove and discard "0" ring seals on housing head. Remove bearing assembly and spacer from worm housing *(NOTE - The spacer and bearing assembly is serviced as a unit).*

Inspection - Check bearing races and roller for pits or scratches. Spacers should fit flat against shoulders in housing and machined surfaces at each end of housing must be smooth and free of nicks or burrs. Replace all parts that show signs of wear.

Worm Connector & Valve Control: Pry worm connector locknut from openings in connector, then slide up on connector far enough to clear the unit. Using Tool C-3321 and Tool C-3326, remove worm connector nut, then slide connector assembly from upper piston rod. Remove valve adjusting cup from inside of worm connector. Pry retaining portion of piston rod nut lock from indents in nut and remove lock. *(CAUTION - Use care when removing lock so as not to damage control spacer).* Remove nut with Tool C-3328. Slide spacer, seal assembly and nut from valve rod and slide housing head off end of valve rod.

Inspection - Piston rod must be smooth on both ends and Nylon insert nut must be tight in valve adjusting cup. Flange inside connector nut should be smooth and housing head should be free from nicks and burrs. Inner bore of valve control rod should show little or no wear from retainers, and edges should be smooth and free from nicks or burrs. Use crocus cloth spread over a flat surface to remove burrs.

►*VALVE CONTROL SPACER NOTE:* Spacer is serviced in two different lengths, with a .001" differential. Spacer must be exactly the same length as space between piston rod nut and shoulder of piston rod. With nut tightened, spacer should roll freely in groove, barely holding its own weight.

Worm Connector: *(CAUTION - When disassembling the worm connector, be careful not to bottom worm shaft in either direction as the ball guides may be damaged causing either a tight or rough operating worm).* Remove ball guide clamp and carefully remove guide (with balls). *(CAUTION - If one or more of the balls are lost or damaged, replace the complete set of 40 balls. Balls are a selected fit and must not be replaced singly).* Hold connector upside down and remove remaining balls by turning connector in and out. Count balls that were removed so that same number may be installed at reassembly. Slide worm out of connector and remove nut lock.

Insp ction - Guide rails on connector should be free of nicks or burrs and slide freely on guides in housing. Ball track on worm should be smooth without pitting or roughness. Check balls for pitting, brinelling or flaking. Check fit of adjusting cup and spacer in connector, if loose, install new spacer; adjusting cup, or both.

Gear Housing: Remove locknut from gear adjusting screw. Remove gear shaft oil seal snap ring, then using Tool C-3350, pull seal out of housing. Remove bolts and washers attaching gearshaft adjusting cover to housing (sealing washers are used on the two bolts that thread through to inside of housing). Discard sealing washers. To remove gearshaft cover, turn the adjusting screw into cover until flush, then spin cover off adjusting screw. Remove and discard cover "0" ring seal. Align gear on gearshaft to clear opening in housing, and using a fibre hammer, rap lightly on end of gearshaft. Slide gear and shaft out of housing. Remove adjusting screw retaining snap ring with pliers, Tool C-3229. Slide adjusting screw, "0" ring seal and retaining washer from end of gearshaft. Remove thrust washer from seat in end of shaft. Discard "0" ring seal.

Inspection - Gearshaft should be free of pits, scores, or signs of excessive wear in seal and bearing contact areas. Gear teeth should be smooth and show a good contact pattern. Needle bearings in cover should be smooth and rotate freely in race.

Piston & Rods: Place a suitable container under gear housing to catch trapped oil, remove piston assembly and rods from housing and disassemble as follows: Grasp upper piston rod firmly, twist slightly and pull piston and lower rod straight out of housing. *(CAUTION-Do not allow lower piston rod to touch piston bore).* Remove snap ring holding lower rod in piston, then carefully work lower rod out of piston to expose piston valve. Remove and discard "0" ring seal and slide piston valve out of piston, using care not to bend valve rod. Support piston assembly using a soft wood block and drive piston pin into upper rod using a ¼" round drift. Using snap ring pliers, remove upper rod retaining snap ring, then carefully work upper piston rod out of piston. Insert wire or paper clip down through piston pin, bend inserted end over through oil passage hole in rod and pull pin out of piston. Remove and discard "0" ring seal. Remove large "0" ring seal from base of upper rod, using a paper clip and remove valve rod "0" ring seals from each end of upper rod. Remove and discard piston rings from each end of piston. Using a 7/16"-14 (standard thread) bolt, remove restrictor valve from lower piston rod. Thread bolt into valve, finger tight. Clamp head of bolt in a vise and rap end of rod with a fibre hammer. Slide valve out of rod. Disassemble valve by inserting a stiff wire into pin hole and pushing out retaining pin. Remove plunger and spring.

Inspection - Restrictor valve plunger should slide freely in valve body and show no signs of sticking. Lower piston rod should be free of pits, burrs, or scratches. Upper rod should be unmarked in seal contact area. Valve port ring inside piston should have a bright polished surface with sharp edges, and the valve rod should slide freely through the "0" ring seals. Check valve rod by inserting valve in piston until centered, then lay piston on flat surface and place Tool C-3333 under valve rod. Rotate piston slowly and check rod

CONTINUED ON NEXT PAGE

1957 "CO-AXIAL" (C nt.)

for straightness. If valve is loose, install a new assembly. Check adjusting cup to make sure it grips valve rod tightly by installing cup on valve rod, then, using a torque wrench (inch-pound) rotate cup which should require a minimum of 5 inch-pounds.

Gear Housing: Drive welch plug from bottom of gear housing (drive from cylinder side). Using a thin bladed screwdriver, pry out lower piston rod thrust pad from gear housing. Remove lower piston rod seal, using Tool C-3450 as follows Insert disc end of tool through opening in end of housing, locating disc between seal and housing shoulder. Using offset (curved) section as a fulcrum, force disc between shoulder and seal until retainer screw almost contacts seal (viewed from opposite end). Drive seal out of housing.

Inspection - Inspect gearshaft needle bearings in housing *(NOTE - Do not remove unless they are damaged).* If lower piston thrust pad is scratched, replace it. Check piston walls for nicks or scratches. All machined surfaces of housing should be smooth and free from nicks and burrs.

REASSEMBLY: *NOTE - Clean all parts with solvent and blow dry with compressed air. Use all new "0" ring seals, coating them with Lubriplate at reassembly.*

G ar Housing: Remove garter ring from new piston rod seal and install seal on Driver, Tool C-3331 with lip of seal toward driver. Insert Pilot, Tool SP-1927 through seal and into driver until bottomed, then insert assembly into housing, keeping tool centered in bore. Drive seal into position, then very carefully work garter spring into seal with two long shank screwdrivers. *(NOTE* - If Tool C-3331-A is used, it will not be necessary to remove garter spring from seal). If gearshaft lower needle bearing was removed, drive bearing into position with Tool C-3333 (lettered end of bearing against driver). *(NOTE* - Outer end of bearing should be 1 1/16" from end of housing when properly seated). Install upper bearing in the same manner, with outer end of bearing flush with end of bore. Place lower piston rod thrust pad in position, align shoulder with recess in housing and press into position.

Pist n & R ds: Slide restrictor valve spring and plunger into valve body, secure with pin, then install assembly into lower piston rod bore. Check plunger for free operation in valve. Install two new valve rod "0" ring seals in each end of upper piston rod, making sure that rings are seated evenly in grooves. Coat a new "0" ring seal with Lubriplate and slide into position in groove on end of upper piston rod. Carefully slide rod into piston, aligning piston pin holes. Align new "0" ring seal over piston pin and insert into piston. Be sure pin is perfectly straight, then tap into piston, using a ¼" drift. *(NOTE* - Pin should be flush in piston). Install retaining snap ring with bevelled side out, **making sure that ends f snap ring d n t bstruct an oil passage** and that it is fully seated in groove. Slide valve and rod into piston and upper rod, carefully working past "0" ring seals previously installed. *(CAUTION - Be careful not to bend th rod).* Slide new "0" ring seal into position in groove on bottom of lower piston rod, then carefully slide rod into piston and down into position. Install retaining snap ring with bevelled side out, **making sure that ends of snap ring d n t bstruct an il passage.** Install new "0" ring seals on each end of piston, then locate Tool C-3344 on gear housing (around cylinder bore). Coat Tool C-3554 with Lubriplate and place over teeth of lower piston rod. Slide piston and rod assembly into cylinder bore, guiding Tool C-3554 out of lower housing as piston is being pushed into cylinder. As piston is installed, align teeth on lower rod for meshing with teeth on gearshaft.

Gear Shaft: Install adjusting screw thrust washer, screw and retaining washer, then install snap ring. Install "0" ring seal on adjusting screw, using Tool C-3401. Install sector gear in mesh with rack and seat shaft to mesh teeth. Check gear timing, using steering gear arm to rotate gearshaft. **Full piston travel must be 2 ".** *(CAUTION - Failure to obtain proper timing will result in a broken gear housing).* Check operation of gears by rotating gear shaft. Place a new shaft oil seal with lip down (coated with Lubriplate) on a piece of clean paper then carefully slide tapered end of sleeve, Tool C-3350 in seal and slide seal back about ¼" on sleeve. Slide sleeve and seal over shaft with lip of seal toward housing until seal contacts housing bore. Slide adapter over sleeve, followed by coupling nut. Install seal in housing by turning nut on shaft threads until shoulder of adapter touches housing. Remove nut and adapter. Wrap tape around sleeve to provide a firm grip, then slide sleeve off shaft using a twisting motion *(CAUTION - Do not use any tool to remove sleeve).* Install "0" ring seal on adjusting cover, place cover on screw and spin down as far as possible. Align cover with bolt holes, then move adjusting screw outward until cover is seated *(CAUTION - Do not force).* Install bolts and washers (with seals), in inside holes and tighten to 30 ft. lbs. Install adjusting screw locknut but do not tighten. Install a new welch plug in bottom of housing.

Valve Control Spacer: Remove garter spring from a new upper piston rod seal and position seal on Driver, Tool C-3331 with lip of seal toward driver. Install seal aligning pilot in end of driver *(NOTE* - If Tool C-3331-A is used it will not be necessary to remove garter spring). Place housing head on a flat surface with single flange side up and drive seal into head until seated, then install garter spring. Install "0" ring seal over shoulder on head, then slide head over piston and down against housing, making sure it is seated. Install connector nut over piston rod with threaded end out. Slide a new control spacer seal into spacer and install retainers. Place Seal Protector, Tool C-3329 over threads on upper rod and slide spacer assembly over tool and down against shoulder of upper rod. Remove tool. Install piston rod nut and tighten with a sharp rap of a hammer on Tool C-3328. Install new lock cap over nut and index with slots in rod. Using a suitable punch, drive outer diameter into recess in nut.

Worm Connector & Valve Control: Install worm into connector and visually align upper portion of passages with ball guide holes. Insert 30 balls (no more), into lower hole by pushing them gently, using rubber end of pencil, and at the same time, oscillating worm. *(NOTE* - When 30 balls have been installed, they should be visible in the hole). Place remaining 10 balls in either half of ball guide, greasing the balls to keep them in place, then place other half of guide over balls. Insert ball and guide assembly into holes in connector and install clamp, lock washers and bolts. Check operation of worm, making sure that it is free to turn to maximum travel of worm shaft. *(NOTE* - Worm should rotate freely by its own weight in either direction). *(CAUTION - Do not allow worm to bottom at either end).* Install valve adjusting cup on end of valve rod. Slide worm connector nut lock over threaded end of connector with tang side facing threads. Slide worm connector over control spacer and screw nut onto connector by hand. Hold worm connector with Tool C-3321, then using Tool C-3326, tighten nut securely. Engage tang of lock with recess in nut, stake lock in hole in connector, then remove tools.

► *TESTING FOR LEAKS·* Align housing head to gear housing, then install Tool C-3555 over head. Install bolts and tighten securely. Install hose fittings, adaptors and test hoses from pump to unit. Fill pump reservoir with Automatic Transmission Fluid Type "A" and have additional fluid available. Install Tool C-3445 through worm shaft (forked end first) and engage valve rod. Remove wire from ignition coil and turn engine over, using the starting motor (this will prevent damaging steering gear unit should the valve be positioned to give excessively fast steering). As steering gear fills, it will self steer *(CAUTION - Be ready to turn the valve to stop the self steering before piston reaches limit of travel, turning valve to right if piston moves up, and to the left if piston moves down).* Fill reservoir. Replace engine ignition coil, start engine and allow steering gear to warm up to normal operating temperature, then check for leaks. *(NOTE - The above valve adjustment is only temporary. Make final adjustment after unit is completely assembled).* After leak test, stop engine and remove tools.

Worm Housing: Install "0" ring seal on smallest land of housing head, then slide bearing race over wormshaft, followed by a thrust bearing and race. Slide spacer and needle bearing assembly into housing past rail guides, then press shoulder of spacer into housing. Turn connector until ball guide is directly down and rails are aligned. Slide worm housing over connector with the vent on top side. *(CAUTION* - Be careful not to force "0" ring seal off housing head). Hold housing in alignment with connector rails, then seat against gear housing. *(NOTE* - Worm housing must meet gear housing with hand pressure only). Install attaching bolts and washers and tighten to 25-30 ft. lbs. Slide bearing spacer over worm shaft with shoulder towards worm, and seat in housing. Slide bearing race thrust bearing and race over worm and down against spacer. Install a new adjusting nut with locking flange up. Pour 14 ounces of Automatic Transmission Fluid Type "A" into upper housing and install filler plug.

► *ADJUSTMENT NOTE* Make worm bearing adjustment, piston valve adjustment, and gear adjustment before installing steering gear. *See "Adjustment" above .*

POWER STEERING PUMP· Different pumps used as follows

Chrysler & Plymouth - *See "Thompson Sleeve Type" under "Power Steering Pumps"*

DeS to (Early) & Dodge - *See "Vickers Vane Type (3-Piece Housing)" under "Power Steering Pumps"*

DeS to(Lat) - *See "Vickers Vane Type (2-Pi ce Housing)" under "Power Steering Pumps"*

CHRYSLER, DE SOTO, DODGE, PLYMOUTH VALIANT "CONSTANT CONTROL" POWER STEERING

Chrysler, DeSoto, Dodge, Plymouth (1958-60)
Valiant (1960)

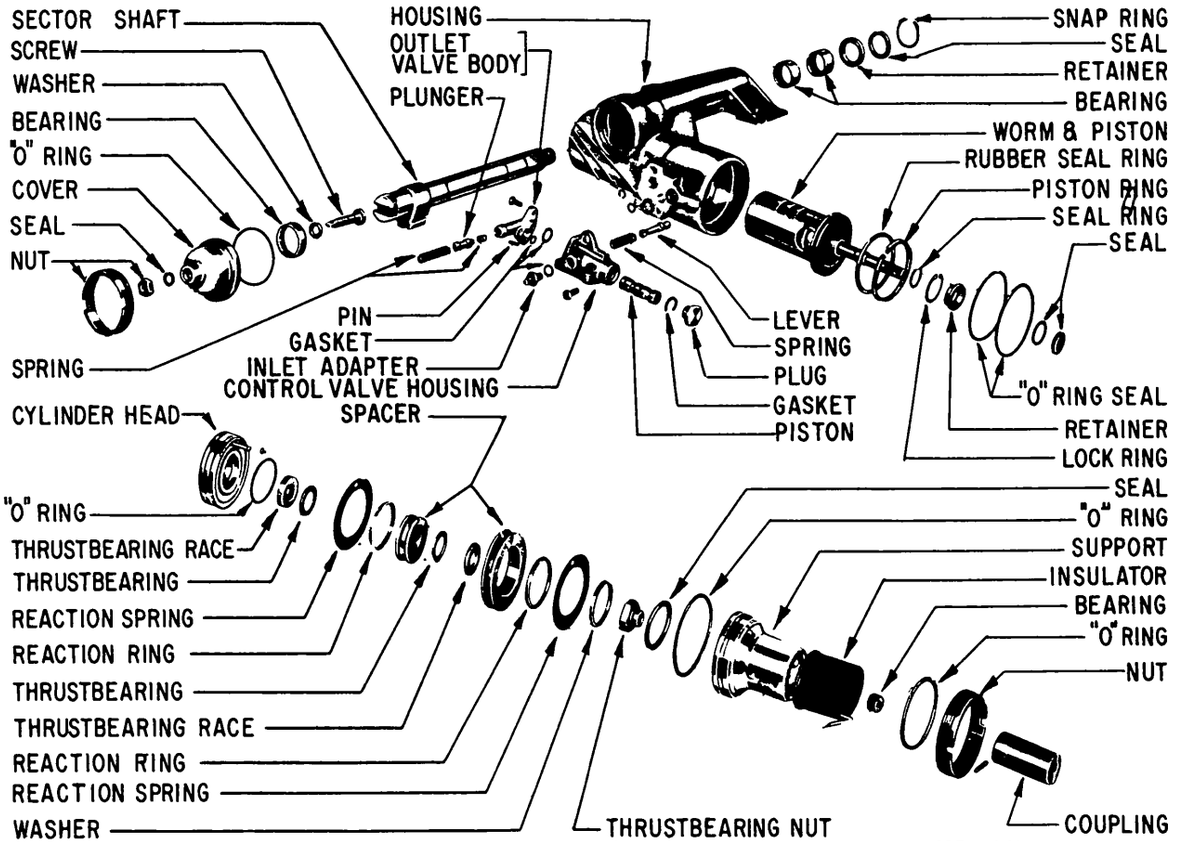
►CHANGES, CAUTIONS, CORRECTIONS

►*1958 POWER STEERING WORM SHAFT PRODUCTION CHANGE:* Power Steering units with new wormshaft are identified by change letter "L" and subsequent letters (after date stamp on housing). New worm shaft has knurled section on coupling adjacent to threads and worm bearing adjusting nut has a tapered flange section. Early and later type shafts are interchangeable in service. Late type adjusting nuts are reusable. *See "Overhaul" for installing new nut or reinstalling old nut.*

►*1958 PRODUCTION CHANGE & TAPPING NOISE CORRECTION (Early Cars):* A back pressure control valve spring was used in cars with Code 8-31-C or later (stamped on lower portion of housing) to correct tapping noise caused by shoulder on back pressure relief valve striking seat in valve bore. To install spring in early cars, proceed as follows:

1) Remove return hose from back pressure valve body, then remove back pressure valve assembly *NOTE* - DO NOT disturb steering control valve body.

2) Remove valve spring retainer pin from valve body and remove spring and piston. A spacer washer may be on top of spring and must be reinstalled.



3) Place valve cushion spring in valve body. *NOTE*- Check through oil passage to see that spring is seated properly and is not cocked. Install piston with chamfered end down against cushion spring, then add pressure control valve spring and retaining spring.

4) Reassemble back pressure valve assembly with "O" ring seal to steering control valve body, and tighten screws to 10 ft. lbs. Reinstall hose and test operation. Check fluid level in reservoir after operating gear.

►*1959 CHRYSLER & DESOTO POWER STEERING "LUMPINESS" FEELING CORRECTION:* This "lumpiness" feeling will be encountered on long sweeping curves and may be caused by recirculating balls of worm and piston assembly crowding and jamming in the ball retainer. To eliminate this condition, a spring and a counterbore was incorporated in each of the ball guide plugs. Later units having this change are identified by the letter "P" or subsequent letters stamped on housing following the date code. On prior units, the ball guide plugs can be replaced by the later type ball guide springs and counterbored plugs which are furnished in Ball Guide Spring Service Package, Part No. 2084215. *See "Overhaul" below for installation procedures.*

►*1959 POWER STEERING PUMP OIL FILLER CAP PRODUCTION CHANGE & OIL LEVEL CHECKING CHANGE:* A new oil pump oil filler cap, without a dipstick for checking oil level is being used in later cars. *See "Lubrication" below for new checking procedure on units with the later type cap.*

►*1960 V8 ENGINE (EXC. 318" ENG.) POWER STEERING PUMP PRODUCTION CHANGE:* A new pump having a larger diameter shaft and seal and a load reaction type belt tensioner is used on some models. The new pump is mounted on a flexible swivel-type mounting to enable steering pump load to be increased when the pump moves outward and increases belt tension. Service procedures are the same as for previous pumps except for belt adjustment. *See "Belt Adjustment" below.*

CHRYSLER, DESOTO, DODGE, PLYMOUTH, VALIANT POWER STEERING GEAR ASSEMBLY

►*1960 DODGE POWER STEERING POOR RETURNABILITY CORRECTION:* This condition may be caused by the steering column jacket bearing being out of place. To correct, remove column jacket assembly and straighten the column jacket bearing retaining tabs and remove bearing. Straighten all three retaining tabs, then reinstall bearing and bend the three tabs down to retain bearing. *NOTE - Make sure large end of bearing tapered inner bore is facing down. Reinstall column jacket assembly. NOTE - A bearing washer, Part No. 2201299 is now used to retain nylon separator in bearing. Washer is placed on upper side of bearing and is held in position with same tabs that retain bearing.*

►**1958 *CHUCK ASSEMBLY PRODUCTION CHANGE:*** **Revised chuck assembly used in later cars. Steering gear units with new chuck assembly are identified by letter "H" or later following date code on gear housing.** ***CAUTION - N w parts are n t int rchang abl individually with pr vious parts and form r steering g ar housing assembly and worm and piston ass mbly are n longer serviced.***

DESCRIPTION: 1958 Models - This power steering assembly consists of an integral power steering gear and hydraulic power unit enclosed in a single housing. The power piston is engaged directly with steering gear worm shaft by recirculating balls and with gear shaft and sector by gears milled into side of piston forming a direct connection between worm shaft and sector shaft. A control valve mounted on the gear housing is operated by a valve lever that is actuated by slight back and forth movement of the worm shaft. In the event oil pressure is interrupted, steering wheel movement will rotate the worm shaft within the power piston causing it to move and rotate sector shaft in same manner as in a manual steering gear.

1959-60 Models: Similar to previous model except as follows: Piston flange is now fitted with a cast iron ring backed up by a rubber ring. Steering gear valve pivot lever has been redesigned. A spring has been added to maintain constant pressure against steering valve housing and a spring loaded back pressure valve is provided which maintains a constant pressure of 35 lbs. in gear whenever steering gear pump is operating.

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH VALIANT "CONSTANT CONTROL" POWER STEERING (C nt.)

OPERATION: With control valve in neutral position, oil under pressure flows through both grooves in valve body, then into chambers on both sides of power piston and into both reaction chambers When steering wheel is turned, the worm shaft moves in piston a few thousandths of an inch, causing center thrust bearing race which is clamped axially to worm shaft to move the same distance. The bearing race thus tips valve pivot lever and moves control valve spool in proper direction to reduce flow in one groove and increase it in the other. Oil then flows from power steering pump through the enlarged orifice to proper side of power piston causing it to move and rotate sector shaft. Simultaneous with turning steering wheel, the restraining force of the reaction spring is overcome which is necessary before center race can move to actuate control valve lever. At the instant power steering is no longer required, the reaction spring and operating oil pressure move race and spool valve back to neutral position. Equal oil flow is directed through unit and no power assist is provided.

ADJUSTMENTS

PUMP BELT ADJUSTMENT: With a 5 lb. load applied midway between the pulleys, belt deflection should be as indicated in table below.

Car Model	New Belt	Used Belt
1958 Chrysler (LC-1)①	②3/32"	②5/32"
1958 Chrysler (Others)	②3/32"	②3/16"
1959-60 Chrysler (All)	③1/8"	③3/16"
1958-60 DeSoto (All)	③1/8"	③3/16"
1958 Dodge (LD-1)	③3/32"	③5/32"
1958 Dodge (LD-2)④	③1/16"	③ 1/8"
1958 Dodge (LD-3)④	③1/8"	③3/16"
1959 Dodge Six	③3/32"	③5/32"
1960 Dodge Six	③3/8"	③ 1/2"
1959-60 Dodge (326" Eng.)	③1/16"	③ 1/8"
1959-60 Dodge (361 & 383" Engs.)	③1/8"	③3/16"
1958-59 Plymouth Six	②3/32"	②5/32"
1960 Plymouth Six	③3/8"	③ 1/2"
1958-60 Plymouth (318" Eng.)	③1/16"	③ 1/8"
1958-60 Plymouth (Exc. 318" Eng.)	③1/8"	③3/16"
1960 Valiant⑤	3/8"	

①- On early models with bolted-on pulleys, adjust deflection to 3/32" (new belt), 3/16" (used belt).
②- Between power steering pump and water pump.
③- Between power steering pump and crankshaft.
④- On early models with bolted-on pulleys, adjust deflection to 1/8" (new belt), 3/16" (used belt).
⑤- With 10 lbs. load applied midway between pulleys.

Belt Adjustment (1960 Models with Load Reaction Belt Tensioner): With engine stopped, loosen adjustment bracket-to-engine bolts, then exert outward pull of 50 lbs. with a spring scale attached to swivel bolt. Hold tension and tighten mounting bolts. *NOTE - Mounting bracket will bear against stop. With engine running, mounting bracket will move away from stop.*

STEERING GEAR ADJUSTMENT: *NOTE - The following adjustments can be made with power steering unit installed on the car.*

Control Valve: With oil reservoir filled to the full mark, operate engine at idle speed to bring steering gear to normal operating temperature. Loosen gear arm (pitman arm) at disconnect, or disconnect arm at steering linkage. Turn gear shaft adjusting screw outward through gear shaft cover to assure no mesh adjustment preload during this adjustment. Loosen valve body attaching screws, then tighten them to 7 ft. lbs Apply oil pressure to the complete unit and position steering gear control valve by tapping one of the control valve screws or on valve end plug to position valve assembly (up or down) on steering gear housing so that torque required to turn gear shaft in both directions is equal within 5 ft. lbs. (turning effort must not exceed 20 ft. lbs in either direction). When valve is properly located, tighten attaching screws to 15 ft. lbs. Adjust gear shaft preload as follows, then reconnect steering arm to steering shaft or to linkage.

Gear Shaft Preload: Loosen adjusting screw until backlash is evident (if not previously done), then tighten adjusting screw until backlash just disappears. Continue to tighten 3/8 to 1/2 turn from this position and tighten locknut to 50 ft. lbs.

LUBRICATION: Check fluid level in reservoir every 5000 miles. Add Power Steering Fluid, Part No. 2084329 as necessary to bring level up to "Full" mark on reservoir. *NOTE* - When checking fluid level, fluid must be at normal operating temperature.

BLEEDING SYSTEM: All air can be expelled from unit by turning steering wheel several times from full right to full left and back again.

HYDRAULIC PRESSURE TEST: Disconnect pump-to-steering gear pressure hose at steering pump and connect test hose C-3388 with proper adapters between pump and gauge C-3309-B with shut-off valve between gauge and steering gear. With engine idling at 500 RPM and oil at normal operating temperature (150° to 170°F., checked with thermometer in reservoir), pressure should be 55-80 lbs. (Exc. Valiant), 35-80 lbs. (Valiant). Increase engine speed to 1000 RPM and slowly close shut-off valve. Pump pressure should be 950-1050 lbs. (Chrysler and DeSoto), 850-950 lbs. (Dodge & Plymouth), 650-750 lbs. (Valiant). *CAUTION - Do not hold valve closed for more than a few seconds.* If pressure is in excess of maximum, check for faulty relief valve. If pressure is less than minimum, power steering pump is defective.

TROUBLE SHOOTING

TROUBLE SHOOTING: Hard Steering - 1) Tires not properly inflated or steering linkage requires lubrication.
2) Low oil level in pump reservoir, loose pump belt, pump belt oily, or oil pump output low.
3) Steering gear not operating properly; caused by one or more of the following conditions:
(a) Cross shaft adjustment too tight or pressure control valve stuck in closed position.
(b) External oil leakage at lower sector shaft oil seal. Sector shaft adjusting screw seal, Sector shaft cover "O" ring seal. Valve housing-to-gear housing "O" ring seals.
(c) Defective or damaged valve lever. *NOTE* - If pump pressure will build up to 850-950 lbs., check the following points: Defective or damaged gear shaft bearings. Dirt or chips in steering gear. Damaged column support worm shaft bearings. Damaged thrust bearings or excessive preload adjustment. Rough, hard-to-turn worm and piston assembly.
(d) Excessive internal leakage. *NOTE* - If pump pressure will not build up to 850-950 lbs., check the following points: Cylinder head "O" rings. Cylinder head reaction seal. Cylinder head worm shaft oil seal assembly. Column support-to-ferrule "O" ring seal. Column support reaction seal.

Poor Recovery From Turns: 1) Tires improperly inflated, steering linkage binding, or wheels not properly aligned.
2) Damaged or defective steering tube bearing, or steering wheel column jacket and steering unit not properly aligned.
3) Steering gear not operating properly; caused by one or more of the following conditions:
(a) Improper cross shaft mesh adjustment or pressure control valve stuck in open position.
(b) Column support spanner nut loose, defective or damaged valve lever, or improper worm thrust bearing adjustment.
(c) Burrs or nicks in reaction ring grooves in cylinder head or column suppert. Defective or damaged cylinder head worm shaft seal ring.
(d) Dirt or chips in steering gear unit, or rough or catchy worm and piston assembly.

Self-Steering or Leads to Either Side: 1) Tires not properly inflated or wheels not properly aligned. Steering wheel off center when car is traveling straight ahead.
2) Valve body out of adjustment. *(NOTE* - If steering to the left, move body down on housing; if steering to right, move body up on housing). Valve lever damaged or column support spanner nut loose.

Temporary Increase in Effort When Turning Steering Wheel to Right or Left: 1) Low oil level, pump belt loose, oil on pump belt, or defective power steering pump.
2) Engine idle speed too slow, air in steering system, or steering linkage binding.
3) Steering gear not operating properly due to external leakage, improper cross shaft adjustment, or excessive internal leakage.

Excessive Steering Wheel Freeplay: 1) Improper cross shaft adjustment, column support spanner nut loose, or improper worm thrust bearing adjustment.

Lack of Assistance: 1) If encountered in one direction, check for oil leaking past worm shaft cast iron oil seal ring or ferrule "O" ring.
2) If encountered in both directions, check the following: Broken "D" ring or worm piston, loose piston end plug, missing reaction seal, slipping pump belt, or low pump output.

Noise in Steering Unit: 1) Buzzing noise in neutral position which stops when steering wheel turned may be caused by a sticking pressure control valve.
2) Noisy oil pump, damaged hydraulic lines, pressure control valve sticking, improper sector shaft mesh adjustment, or air in system.

STEERING WHEEL & HORN BUTTON REMOVAL & INSTALLATION

Chrysler & DeSoto (1958-59): Disconnect battery, then turn ornament counterclockwise and remove. Disconnect horn terminal wire. Remove three screws and three

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH VALIANT "CONSTANT CONTROL" POWER STEERING (Cont.)

bushings, then remove horn ring. Remove horn contact ring switch from steering gear hub, then loosen wheel nut three turns and pull wheel with Tool C-612 or C-3428 (depending on model).

Chrysler & DeSoto (1960): Disconnect battery, then remove steering wheel ornament by pressing down on center and turning ornament ¼ turn. Disconnect horn wire and remove three screws, bushings, horn blowing ring, rubber insulator and horn terminal plate. Loosen steering wheel nut and use puller, Tool C-3428 to loosen steering wheel

Dodge & Plymouth (1958-59): Disconnect battery, then center steering wheel and remove two screws under medallion. Remove medallion and remove horn wire from terminal on travel plate and insulator assembly. Remove horn ring, travelplate and insulator assembly, contact spring plate and ground plate. Push wire aside and pull steering wheel with Tool C-3428 or C-612.

Dodge & Plymouth (1960): Disconnect battery. Remove steering wheel ornament by removing screws from underside of steering wheel and remove stationary plate, bushings, horn ring and attaching screws. Disconnect horn wire at stationary plate, then loosen steering wheel nut three turns and pull wheel with Tool C-3428.

Valiant (1960): Disconnect battery, then rotate horn button ¼ turn counterclockwise and remove button. Remove three screws and bushings from horn button base and lift out base or horn ring. Disconnect wire from horn switch and remove switch, then remove steering wheel nut and washer. Place wheels in straight ahead position and install puller, Tool C-612 and remove steering wheel.

STEERING GEAR REMOVAL & INSTALLATION

Steering Gear Removal: Except Valiant - With steering wheel removed, remove directional signal cancelling mechanism then remove retainer snap rings from groove in steering tube at top of bearing with Tool C-3229. Remove jacket tube shield to allow access to column tube clamp and remove screws attaching steering jacket tube clamp at instrument panel and remove clamp. Raise carpet and move rubber grommet up on jacket column, then remove screws attaching rubber dust boot to firewall. On Imperial models, remove floor inspection panel. Loosen jacket tube clamp at steering gear housing. Remove cotter key and nut at drag link and disconnect link from steering arm, then remove steering arm nut and washer at steering gear shaft. Slide Tool C-3646 up on steering arm and place shoe of puller behind steering arm and pull steering arm from gear shaft. *CAUTION - Do not remove steering arm by prying with a lever or striking with a hammer.* Disconnect hydraulic brake line at master cylinder and brake tee and remove line, then disconnect pressure and return hoses at steering gear (fasten ends of hoses above reservoir oil level and cap all openings). Slide jacket tube up and off steering gear through drivers compartment, then remove jacket tube upper spring and retainer. Remove steering tube coupling pin, two plastic inserts, horn ground strap, rubber insulator and upper steering tube. Remove gear housing to frame bolts, washers and alignment wedge. Slide steering gear upwards and toward rear of car and at the same time raise lower end of gear and remove gear from engine compartment. *NOTE - On cars with Ram Jet Manifolds, to remove gear, raise lower end of housing in a clockwise motion towards panel until gearshaft end of housing and shaft will clear "A" frame of front suspension, then tilt entire gear assembly towards engine slightly to allow swinging steering gear assembly downward through opening at fender side panel (fender side panel removed). Gearshaft end of housing should go through opening first and the housing should be rolled through opening end-over-end.*

Installation - Reverse removal procedures and note the following: Make sure there is at least 1/16" clearance between bottom face of jacket tube clamp and column support spanner nut. With steering gear completely installed (gear assembly-to-frame bolts not tightened), tighten front upper and lower gear housing to frame attaching bolts to 20 ft. lbs. Install wedge over rear bolt between housing and frame so that tapered surfaces match, tapping it lightly into place, then tighten all three attaching bolts to 50 ft. lbs.

Valiant - Remove steering arm from steering gear shaft with Tool C-3646, then disconnect hydraulic lines from steering gear. Remove bolts attaching steering gear to frame and remove bolt from coupling clamp at upper end of steering gear worm shaft. While supporting steering gear, tap coupling upward with a mallet until it is free from worm shaft splines, then lift out steering gear.

Installation - Reverse removal procedures and note the following: Tighten steering gear-to-frame attaching bolts to 75 ft. lbs. and steering arm nut to 85 ft. lbs.

OVERHAUL

►*1959 CHRYSLER & DESOTO POWER STEERING "LUMPINESS" FEELING CORRECTION: See "Changes, Cautions, Corrections" above and note the following procedure for installing Ball Guide Spring Service Package, Part No. 2084215.* With steering unit removed from car, remove power train from steering unit, then remove coupling pin. Remove valve assembly and valve lever, then remove cross shaft cover spanner nut. With unit in the "on-center" position withdraw cross shaft until teeth clear the housing. Rotate shaft 180° and allow ends of teeth to rest on housing. Turn coupling full right and remove the coupling. Remove jacket support spanner nut. Firmly install a suitable drift through hole in jacket support to engage groove in worm shaft (locking these two parts together). While holding drift, pry on piston teeth with a soft metal tool. *NOTE - With this procedure, the worm will be all the way into piston and power train parts will be resting against piston flange. Cylinder head, center race and spacer assembly and the jacket support must be maintained in close contact with each other. This will eliminate the chance of Teflon sealing ring on worm shaft from becoming disengaged from its mating sleeve retained in cylinder head. It will also eliminate possibility of reaction rings becoming disengaged from their grooves in both cylinder head and column jacket support. HOLD THESE PARTS OF POWER TRAIN TOGETHER.* Clamp piston of power train in a vise in vertical position (use a soft jawed vise). Hold cylinder head center race and spacer assembly, and jacket support together, then apply a vertical upward force to cylinder head. The cylinder head will separate from piston as the worm rotates and withdraws from piston. Place a socket or other suitable block between piston flange and cylinder head. Pour clean solvent or cleaning fluid around worm and into cavity of piston until cavity is filled, then hold cylinder head, center race and spacer assembly and jacket support together. Remove block between piston flange and cylinder head. By applying a vertical force, cause the worm to rotate and screw into and out of piston. This will agitate and circulate the cleaning fluid inside the piston and cause it to dilute the residual hydraulic oil. *CAUTION - The above procedure is important to insure that the return guide does not adhere to guide plug when guide plug is removed from piston. If the return guide is removed from the piston, or loses contact with worm by 3/16", one or more of the three balls encased in track of return guide will be displaced. One or more of these balls will lodge themselves in the wrong groove outside the normal ball circuit. If this should occur it may be possible to recapture the displaced balls by using a magnetized drift or rat-tail file. If balls are recaptured, place them in track of the return guide, then smear petroleum jelly over the balls to make them adhere to guide. Reinstall balls in piston. If the balls cannot be recaptured it will be necessary to remove all balls and rebuild this circuit. This should be avoided if possible. The only other alternative is to replace worm and piston assembly.* While holding the cylinder head, center race and spacer assembly and jacket support together, withdraw the worm as far as possible from piston. Remove power train assembly from the vise and drain off cleaning fluid. Hold the same parts together and rotate worm into piston until cylinder head rests on piston flange. Reclamp power train into the vise in a horizontal position with either one of the guide plugs upward. Install conical springs from service package, Part No. 2084215 into counterbore in new plugs. *NOTE - Large diameter of spring must contact counterbore in plug.* Retain spring in plug with a small amount of petroleum jelly. Unscrew and remove old guide plug from piston. *CAUTION - Do not remove return guide. Guide plug is staked in place. Do not attempt to remove staking. Force the plug in a counterclockwise direction to loosen by shearing the staking. Remove any chips that may result. Hold return guide down against worm and gently rotate worm in both directions to make sure it operates freely and that the return guide is in position against worm.* Carefully install the new plug and spring assembly and tighten to 50 ft. lbs. Use a ¼" flat nosed punch and stake flange of plug into locking flat provided in piston so plug cannot loosen. *CAUTION - Guide plugs must be tight.* Turn power train over and install opposite plug in same manner. Check end plug in piston. If necessary, tighten to 100 ft. lbs. Install power train in housing and reassemble steering gear unit.

►*NOTE:* Clean gear assembly thoroughly in suitable solvent and install unit in holding fixture C-3323. Each part removed should be thoroughly washed in solvent and dried by compressed air. Handle parts carefully to avoid nicks or burrs. Use crocus cloth to remove nicks or burrs being especially careful not to round off

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH VALIANT "CONSTANT CONTROL" POWER STEERING (Cont.)

sharp edged portions of two lands on steering gear valve. Discard old "O" ring seals and lubricate new "O" ring seals with petrolatum.

DISASSEMBLY: Drain unit through pressure and return connections by turning steering tube coupling from one extreme to the other. Support coupling while driving pin out to avoid damaging bearings. Remove valve body housing screws, valve body, and three "O" rings. Pry under spherical head to remove valve lever. *CAUTION - DO NOT use pli rs, and DO NOT collapse slotted nd f valv l v r.* Loosen gear shaft adjusting screw locknut and remove gear shaft cover nut with wrench Tool C-3633. Rotate worm shaft to full turn right, then return worm shaft and piston to center of travel and remove gear shaft and cover as an assembly. *CAUTION - Oil will discharg when shaft and cover are pulled from housing.* Remove steering column support nut with Tool C-3634 and remove tanged washer. *NOTE - Turn worm shaft to full right to compress parts and back off as n c ssary to align holes in column support and worm shaft.* Place drill rod through holes in jacket support and worm shaft (to keep parts from turning), and carefully remove power train as a complete assembly. *CAUTION - Oil will be expelled when power train is b ing r mov d.*

P w r Train Disass mbly (All Models) - Place power train in soft jawed vise. *NOTE - Do not turn worm shaft mor than one-half turn during disassembly.* Remove column jacket support assembly, reaction spring, reaction ring and spacer, ferrule "O" ring center, and bearing spacer. Hold worm shaft from turning, then turn nut slightly to left (to shear staked portion of nut) and carefully pick out locking portion of bearing adjusting nut from notch in worm shaft. *CAUTION - B sur staked portion is removed from slot of worm shaft to avoid damaging worm shaft threads.* Remove thrust bearing nut, upper thrust bearing race (thin), upper thrust bearing, center bearing race, lower thrust bearing, lower thrust bearing race (thick), lower reaction ring, and lower reaction spring. Remove head assembly. *NOTE* - Worm and piston assembly furnished as a complete assembly only.

Column Jacket Support Disassembly - Remove worm shaft upper seal with puller Tool C-3638. *NOTE* - Column jacket support and worm shaft upper bearing are serviced as an assembly. Remove large "O" ring from groove in jacket support, then remove reaction seal from groove in face of jacket support by blowing air pressure in ferrule chamber. Inspect grooves for burrs. Be sure there is no obstruction in passage from ferrule chamber to upper reaction chamber.

Cylind r Head Disassembly - Remove two "O" rings from two outer grooves in cylinder head, then remove lower reaction "O" ring from groove in face of cylinder head (use air pressure at oil hole located in groove between the two "O" ring grooves). Inspect worm shaft seal in cylinder head counterbore for possible damage, replace cylinder head seal if necessary. Check oil passage in ferrule for obstruction and check lands of cylinder head for burrs.

Ste ring Valv Disass mbly - Compress pressure control valve spring and remove spring retainer pin, spring, and pressure control valve piston. Remove pressure control valve body-to-steering valve screws and remove valve body. Carefully shake out valve piston. *NOTE* - Replace complete valve assembly if steering valve or valve housing is damaged. DO NOT remove valve and plug unless inspection indicates a leak at seal.

Gear Shaft Disassembly - Remove gear shaft adjusting screw lock nut and unscrew cover from adjusting screw. Remove screw and washer from "T" slot in end of gear shaft, then remove small "O" ring from top of cover and large "O" ring from base of cover. *NOTE* - Gear shaft cover and bearing are serviced as an assembly only.

Steering Gear Housing Disassembly - *NOTE* - Steering gear housing with inner and outer gear shaft needle bearings is serviced as an assembly. Attach housing to fixture Tool C-3323 and install in vise. Remove oil seal snap ring and seal back-up washer, then remove gear shaft oil seal with adapter SP-3056 and Tool C-3350 as follows: Slide threaded adapter SP-3056 over end of gear shaft and install threaded nut section of Tool C-3350 on shaft. Maintain pressure on adapter SP-3056 with nut of Tool C-3350 while turning adapter, forcing it into seal until it bottoms in seal. Apply two half rings and retainer over both portions of tool. As hexagon nut is removed from shaft the seal will be pulled from housing. *NOTE* - Inspect steering housing gear shaft needle bearings for broken or rough needles.

REASSEMBLY: Steering Gear Housing - Install gear shaft oil seal in gear housing (lip of seal toward needle bearing) using adapter Tool SP-3052 and Tool C-3350. Place adapter against seal and tool nut on threaded end of gear shaft. Tighten tool nut until adapter shoulder contacts housing, then install oil seal back-up washer and snap ring. *NOTE* - Be sure snap ring is properly seated in groove.

Gear Shaft Reassembly - Place adjusting screw washer over adjusting screw and alide both into "T" slot of gear shaft. Screw cover onto adjusting screw until gear shaft bottoms in cover. Lubricate new small "O" ring and install it over adjusting screw into position at top of gear shaft cover. Install adjusting screw lock nut on adjusting screw but do not tighten. Lubricate a new large "O" ring and "O" ring groove heavily with petrolatum, then install "O" ring in groove on lower face of gear cover.

Steering Valve Reassembly - Install valve in valve housing so that valve lever hole is aligned with steering gear valve lever opening in bottom of valve housing. Valve must fit smoothly in housing without sticking or or binding. Install end plug with new seal and tighten to 50 ft. lbs. Lubricate pressure control valve piston and slide it into pressure control valve body (nose end first), then install pressure control valve spring on top of valve piston. Compress spring and install spring retainer pin through both holes at top of pressure control valve body. Assemble pressure control valve body to main valve and tighten two screws to 10 ft. lbs. Install new copper sealing gasket and fitting in threaded hole on top of valve body, tighten fitting to 30 ft. lbs.

Cylind r Head Reassembly - Lubricate two large "O" rings and install in grooves on cylinder head. Install the lower reaction seal in groove in face of cylinder head. The small "O" ring for the ferrule groove should be installed after worm shaft bearing preload has been established, otherwise "O" ring will be damaged by reaction springs.

Column Jacket Support Reassembly - Install worm shaft upper seal with sealing lip toward bearing. Use Tool C-3650 and drive seal in until tool bottoms on casting to obtain proper compression of rubber seal. Lubricate reaction seal and install in groove in face of column jacket support with flat side of seal out.

Power Train Reassembly (1958 Models) - Place piston on bench with worm shaft up. Slide cylinder head assembly (with ferrule up) on worm shaft. Check worm shaft seal ring to be sure gap is closed to avoid breaking ring as cylinder head moves against piston flange. Lubricate and install each item in the following order: Lower thrust bearing (thick), lower thrust bearing, lower reaction spring (with small hole over ferrule), lower reaction ring (flange up so ring protrudes through reaction spring), center bearing race, upper thrust bearing, upper thrust bearing race (thin); then start worm shaft thrust bearing nut but do not tighten. Turn worm shaft counterclockwise one-half turn *(CAUTION - Shaft must not be turned out more than one-half turn or cylinder head seal will clear oil ring on worm shaft).* Hold worm shaft in this position while tightening nut to 10 ft. lbs. (early worm shaft), 50 ft. lbs. (late worm shaft to stretch threads). Rotate worm center bearing race several times to position parts. Loosen thrust bearing adjusting nut and retighten it to give a bearing torque of 8-12 inch ounces (early worm shaft) or 8-16 inch ounces (late worm shaft). Check torque by placing several rounds of cord around center bearing race (make loop in end of cord and hook on distributor breaker arm spring scale No. MTU-36). Pull on scale to rotate bearing race should be 8-12 ozs. (early worm shaft) or 8-16 ozs. (late worm shaft). Stake bearing adjusting nut into depression in worm shaft (early type) or nut flange into knurled section of worm (late type), with large radius chisel (early type) or standard drift with ¼" flat point diameter (late type) so staking has to be sheared to remove nut. Recheck torque after staking nut. Install center bearing spacer with dowel pin in slot of center bearing race and with valve lever hole in center bearing spacer and race aligned. Install inner and outer reaction rings (flange down), then install upper reaction spring with cylinder head ferrule through small hole and outer reaction ring protruding through large hole. Install new "O" ring in ferrule groove. Lubricate small bore of column jacket support (for cylinder head ferrule) and install jacket support assembly over worm shaft (carefully engaging cylinder head ferrule and "O" ring and making sure reaction rings enter groove in jacket support assembly). Align parts of power train so valve lever hole in center bearing spacer is 90° counterclockwise from piston rack teeth and lock all parts to worm shaft by entering suit-

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH VALIANT "CONSTANT CONTROL" POWER STEERING (Cont.)

able drift through jacket support and worm shaft groove.

Power Train Reassembly (1959-60 Models) - With Tool C-3676 held in vise, place piston and ring assembly in tool with piston and ring resting in tool land. Pressing down on piston will cause piston ring to bottom in its groove, forcing open ends of ring upwards for ease of locking the piston ring (ring should be positioned with ring hooks in line with ball guide hole). *NOTE - Positioning hooks in this manner will control internal leakage through the ring.* Wire brush knurled area of worm shaft to remove staking deposits Lubricate each part with Automatic Transmission Fluid, then place piston on bench in a vertical position (worm shaft up). Install cylinder head assembly on worm shaft, making sure that gap on worm shaft seal is closed to avoid damaging the ring when cylinder head is bottomed against piston top flange. Install lower reaction plate over ferrule on cylinder head, then install lower reaction ring on pressure plate with flange up so that ring protrudes through pressure plate. Lubricate following parts with Automatic Transmission Fluid and slide them over shaft in the following order Lower (thick) thrust bearing race, lower thrust bearing, center bearing race, upper thrust bearing and upper (thin) thrust bearing race Install a new worm shaft thrust bearing nut and tighten nut as follows Grip piston assembly in a soft jawed vise, then turn worm shaft counterclockwise one-half turn and while holding worm shaft in this position, tighten worm shaft nut to 50 ft lbs to preset the bearings. *CAUTION - If worm shaft is turned more than one-half turn, the cylinder head sleeve will clear the oil seal ring on worm shaft Always position worm shaft oil seal ring before bottoming the cylinder head against piston top flange to avoid damaging oil seal ring* Loosen the adjusting nut and place several rounds of cord around center bearing race, then make a loop in one end of cord and hook the loop of a distributor breaker arm spring scale (Tool MTU-36) in the cord loop Pulling cord will cause bearing race to rotate Retighten worm bearing adjusting nut while pulling on the cord with the scale If adjusting nut is tightened properly, reading on scale should be 8-16 ounces (12 inch ounces preferred) while bearing race is turning. *CAUTION - Place a support under the adjusting nut during the staking operation to avoid brinnelling piston and worm bearings* Stake the upper part of worm shaft adjusting nut into knurled area of shaft as follows Hold a ¼" flat end punch on centerline of worm shaft and perpendicular to worm shaft at a slight angle to nut flange Strike the punch a sharp blow with a hammer and recheck preload If adjusting nut moved during the staking operation, it can be corrected by striking the nut a glancing blow in direction required to regain proper preload After proper preload, stake the nut at three more locations 90° apart around upper part of nut. To test staking, torque nut to 20 ft. lbs in either direction If nut does not move, the staking operation is satisfactory. Recheck adjustment Install center bearing spacer assembly over center bearing race and engage dowel pin of spacer in slot of race and slot of spacer entered over cylinder head ferrule *NOTE - This will align valve lever hole in center bearing race with valve lever hole in center bearing spacer assembly* Place reaction ring (outer) with flange, down against center bearing spacer. Place reaction ring (inner), without flange, inside of the outer reaction ring, with flange, and install upper reaction pressure plate over both reaction rings and over cylinder head ferrule and "O" ring making sure reaction rings enter circular groove in jacket support *CAUTION - Form a .0015" feeler into a coil and insert with jacket support to protect seal lip when installing over worm-shaft serrations* Align parts on power train so that valve lever hole in center bearing spacer assembly is 90° counterclockwise from piston rack teeth and lock all parts in worm shaft by entering a drill rod or suitable drift through jacket support holes and groove in worm shaft

Steering Gear Reassembly (All Models) - Place housing in Tool C-3323 in approximate car position, then lubricate bore of housing with petrolatum and carefully install power train assembly with center bearing spacer valve lever UP to align with control valve lever clearance hole in steering gear housing. *NOTE - Place a .0015" feeler to cover aligning notch in steering gear housing to protect "O" ring seals when installing gear train. Make sure cylinder head is bottomed on housing shoulder. DO NOT remove power train locking pin until all parts are positioned in steering gear housing.* Align valve lever hole in center bearing spacer exactly with clearance hole in housing (use Aligning Tool C-3649). *CAUTION - Do not remove tool until spanner nut is securely tightened.* Install column support spanner nut and tighten to 110-200 ft. lbs. with Tool C-3634. Set piston at center of travel and install gear shaft and cover assembly so that sector teeth index with piston rack teeth. Make sure "O" ring is positioned. Install cover spanner nut and tighten to 110-200 ft. lbs. Install valve lever (double bearing end first) into center bearing spacer through hole in steering housing so that slots in valve lever are parallel to worm shaft, then engage anti-rattle pin in center bearing race. Install valve body on housing making sure that valve lever enters hole in piston. Be sure "O" ring seals are in place, then tighten valve mounting screws to 30 inch pounds.

Bench Test & Adjustment (All Models) - Connect test hoses C-3211 and C-3318 with proper adaptors to hydraulic pump on car with pressure gauge C-3309-B installed between pump and steering gear. Expel all air from unit by turning worm shaft several times to right and left. Temporarily tighten valve body attaching screws to 7 ft. lbs., then with gear shaft on center, tighten gear shaft adjusting screw until backlash just disappears. Temporarily tighten 1¼ turn from this position and while holding adjusting screw, tighten locknut. *NOTE - This procedure will bring piston rack and sector teeth in full alignment.* Turn off hydraulic power to unit and operate unit manually 180° from center in each direction. With hydraulic power to unit and with gear shaft on center plus or minus 2°, readjust gear shaft backlash. This will require loosening adjusting screw until backlash is evident, then retighten adjusting screw until backlash just disappears. Continue to turn adjusting screw for 3/8 to 1/2 turn from this position and tighten locknut to 50 ft. lbs. to maintain this setting. Starting at a point at least one full turn either side of center, the torque at gear shaft required to turn unit through center at 2 RPM in each direction will not exceed 20 ft. lbs. or vary more than 5 ft. lbs. from right to left. Position steering valve to obtain equal torque and tighten valve body attaching screws to 15 ft. lbs. With unit at or near full turn in either direction, attempt to return the unit to center by applying a torque wrench at steering gear cross shaft Hold worm shaft until cross shaft torque builds up to 50 ft. lbs. Release worm shaft and maintain a constant steady pull on cross shaft (turning cross shaft slowly). If cross shaft torque does not drop to 25 ft. lbs. maximum as the piston passes through center, check for too much interior drag, binding valve lever, binding valve spool, or cross shaft adjustment is too tight. With unit under power, but with no load, the torque required to rotate the worm shaft through an angle of 180° (90° either side of center) shall be 6-9 inch pounds. Disconnect test equipment and mounting fixture and install unit in car.

HYDRAULIC PUMP

HYDRAULIC PUMPS: Various types used as follows:

"Slipper Type" Constant Displacement Pump - Used on 1958 Chrysler, DeSoto & Plymouth; 1959-60 All Models. *See "Chrysler, DeSoto, Dodge, Plymouth, Valiant (Slipper Type)".*

Thompson Sleeve Type - Used on 1958 Chrysler. *See "Thompson Sleeve Type".*

Vickers Vane Type (2-Piece Housing) - Used on 1958 DeSoto & Dodge. *See "Vickers Vane Type (2-Piece Housing)".*

EDSEL & LINCOLN "TORSION BAR" POWER STEERING

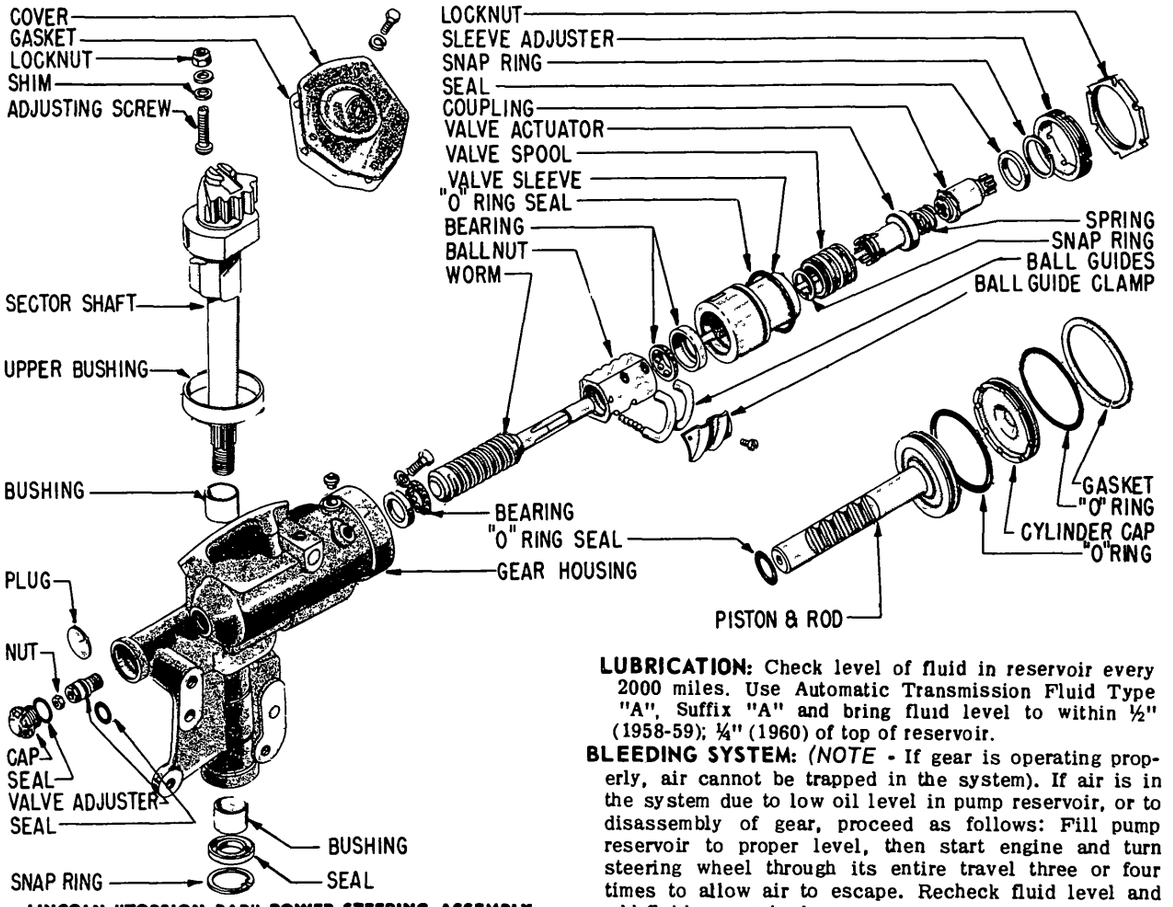
Eds l (1958) See Note below.
Linc ln (1958-60) See Note below.

►*1958 EDSEL POWER STEERING NOTE: Linkage type power ste ring units used on Pacer and Ranger models and on arly Citation & Corsair models.*

►*1958 LINCOLN POWER STEERING NOTE: "Saginaw ln-Lin " power ste ring units used on early models.*

►CHANGES, CAUTIONS, CORRECTIONS

►*1958 CYLINDER END CAP LEAKAGE CORRECTION:* Fluid leak at cylinder end cap (when cap is not distorted or blown out or housing is not damaged) can be corrected by installing new "O" ring No. WAN-33822-A and snap ring WAN-33823-B. *CAUTION - Both items can be replaced with gear in car by working end cap out with fingers. Use of compressed air will cock and wedge cap so it cannot be removed.*



►*1958-59 STEERING GEAR "HISSING" NOISE CORRECTION:* A steering gear "hissing" or "whistling" noise when steering wheel is turned may be caused by inlet tube seat in gear assembly being deformed due to overtightening of pressure hose fitting. To correct, replace tube seat in gear assembly.

►*1959 EATON ROLLER TYPE POWER STEERING PUMP NOISE CORRECTION:* To eliminate the noise in pumps (after cold start), install revised pump carrier, with rollers and cam, Kit No. B9MY-3A711-A. Pumps built after March 11, 1959 have the new parts which are identified by a circled "A" and the words "This Side Up" marked on side of carrier. *See "Eaton Roller Type" Pow r Steering Pumps*

DESCRIPTION: Piston type hydraulic assist power unit having a torsion bar operated control valve combined with a ball nut and worm steering gear enclosed in a single housing. Hydraulic fluid under pressure is supplied to steering gear by a positive displacement type pump. Beginning with 1960 models, steering gear housing, piston rod, cylinder cap and cylinder cap retaining ring were changed to accommodate internal gear stops on power piston and for the later type double lipped sector shaft seal which replaced the former single lip seal. Manual steering is available at all times in the event of loss of hydraulic pressure.

PUMP BELT ADJUSTMENT: ½" deflection with moderate pressure on belt midway between pulleys. Move bracket on support to adjust.

STEERING GEAR ADJUSTMENT: Centering Valve Spool - *(NOTE - This is the only steering gear adjustment that can be made with steering gear installed in car).* Attach pressure gauge in high pressure line between power steering pump and steering gear. Start engine and rotate wheel several times to bring oil up to normal operating temperature. With a spring scale on rim of steering wheel, and steering gear centered, note the amount of pull required to make a left and right hand turn. The difference should not be more than ½ lb. If more than ½ lb., remove adjuster cap at lower end of steering gear and install Tool 3553-K. Loosen locknut and turn adjusting wrench in the direction of the lighter scale reading. *(NOTE - If less force required to turn wheel to left than to right, turn adjusting wrench to the left).* Recheck reading and lock jam nut. Install cap.

LINCOLN "TORSION BAR" POWER STEERING ASSEMBLY

Worm Bearing Preload & Sector Mesh Adjustments - Disconnect steering gear pitman arm from steering connecting link, loosen sector adjusting screw nut and back off adjusting screw. Attach spring scale to rim of steering wheel. Pull required to keep wheel moving from one complete turn off high spot should be ½ - 2/3 lbs. When preload not correct, proceed as follows: Loosen steering shaft bearing adjuster lock nut and tighten or back off adjuster until preload is within specifications, then tighten lock nut and recheck preload. Turn steering wheel to either stop then return 2 1/8 turns to center point. Turn sector adjusting screw until steering wheel pull is 1-1½ lbs. (1958-59); 1½-2 lbs. (1960) to rotate worm through center point. Tighten sector adjusting screw locknut and recheck mesh adjustment. *NOTE - Ther should be no backlash at 30° ither sid of center point. R install pitman arm.*

LUBRICATION: Check level of fluid in reservoir every 2000 miles. Use Automatic Transmission Fluid Type "A", Suffix "A" and bring fluid level to within ½" (1958-59); ¼" (1960) of top of reservoir.

BLEEDING SYSTEM: *(NOTE* - If gear is operating properly, air cannot be trapped in the system). If air is in the system due to low oil level in pump reservoir, or to disassembly of gear, proceed as follows: Fill pump reservoir to proper level, then start engine and turn steering wheel through its entire travel three or four times to allow air to escape. Recheck fluid level and add fluid as required.

HYDRAULIC PRESSURE TEST: Connect pressure gauge in pressure line between pump and steering gear housing. Let engine idle until oil reaches operating temperature, then turn steering wheel for a full right and full left turn to the wheel stops. *(CAUTION - Hold whe ls in this position only long enough to obtain an accurat reading).* Pressure should be 900-1150 lbs. (1958); 975-1100 lbs. (1959-60). If pressure is less than minimum specification, close valve at gauge and note pump pressure. If it is low with valve closed, pump is not operating properly. If pressure goes up with valve closed, low pressure in system would be due to internal leakage in steering unit (providing all connections are tight).

SECTOR SHAFT OIL SEAL: Removal - Raise front of car and remove sector shaft (pitman arm) nut. Use Puller 3590-AA (1958); 3590-E (1959-60) and remove pitman arm, then pry seal out of housing.

Installati n - Place Seal Adapter 3576-J on sector shaft, then place seal on adapter. Install seal with Tool 3591-A. Install pitman arm and sector shaft nut,

CONTINUED ON NEXT PAGE

EDSEL & LINCOLN "TORSION BAR" POWER STEERING (Cont.)

tighten nut to 120-130 ft. lbs. Fill system with Auto. Trans. Fluid Type "A".

TROUBLE SHOOTING

►*NOTE* Conditions listed below are attributable to Power Steering Units and do not include items common to both Conventional & Power Steering.

HARD STEERING: Improper gear adjustment, insufficient or incorrect hydraulic fluid, pump belt out of adjustment, pump output low, air in system, valve spool out of adjustment, or valve spool sticking.

HARD STEERING (Straight Ahead): Steering adjustment too tight, steering gear shaft binding.

HARD STEERING (Turning or Parking): Oil level low, pump pressure low, oil leakage past "O" rings, pressure loss between valve spool and sleeve or past piston ring or scored housing bore.

LOOSE STEERING: Fluid level low, insufficient mesh load, insufficient worm bearing load or valve spool out of adjustment.

WANDERING: Steering gear adjustments too tight or gear backlash excessive.

ROAD SHOCKS: Improperly adjusted steering gear.

BINDING OR POOR RECOVERY: Steering gear binding or out of adjustment, valve spool binding due to dirt or burred edges, valve spool out of adjustment, interference at sector shaft arm and ball stud.

LOSS OF POWER ASSIST: Pump inoperative, lines damaged, power cylinder damaged, valve spool out of adjustment.

LOSS OF POWER ASSIST (One Direction): Valve spool out of adjustment, by-pass valve in control valve inoperative.

NOISY PUMP: Air being drawn into pump, lines touching other parts of car, oil level low, excessive back pressure from obstructions in line, or excessive wear of internal parts.

POOR RETURN TO CENTER: Valve spool sticking or out of adjustment.

STEERING WHEEL SURGE WHEN TURNING: Valve spool sticking.

STEERING WHEEL & HORN BUTTON REMOVAL & INSTALLATION

Edsel (Pushbutton Shift Control) Type: Removal - Disconnect battery then pry off button trim plate medallion Remove two screws from trim plate and lift off plate Pull off pushbuttons and unscrew three screws from inside horn ring and hub, and lift off ring and trim pad Remove three nuts holding horn blowing contact plate assembly and steering wheel to lower hub, then lift contact plate out of hub, and remove steering wheel

Installation - Reverse removal procedure

Lincoln (1958-59): Removal - Remove cap and emblem from wheel by inserting a flat implement between steering wheel hub and horn ring and pushing up Remove steering shaft nut, then remove wheel with Tool 3600-A Remove three screws from rear of steering wheel hub and remove horn ring, coil spring and contact ring or insulator

Installation - Reverse removal procedure

Lincoln (1960): Removal - Remove cap and medallion from steering wheel by depressing and turning cap counterclockwise Remove steering shaft nut and remove wheel with Tool 3600-AA Remove turn signal indicator cam from steering wheel hub, then remove four nuts retaining horn ring and brush plate to steering wheel Separate parts being careful to note insulator washers on each retaining bolt *NOTE - If necessary to replace horn contact wire assembly, remove turn signal lever and switch plate, steering shaft bearing retainer and lower column shroud. Disconnect steering shaft at coupling and remove shaft and bearing Remove two flange-to-selector lever socket nuts and separate the two parts. Remove horn wire bracket screw and remove wire assembly*

Installation - Reverse removal procedure, positioning turn signal indicator cam on steering wheel hub so opening in side of cam will face 180° opposite turn signal indicator switch assembly when steering wheel is installed in straight ahead position Tighten steering wheel nut to 20-25 ft lbs and stake nut in position

STEERING GEAR REMOVAL & INSTALLATION

REMOVAL: Edsel - Remove battery ground cable at battery, cover front seat and seat back, disconnect signal wires at connectors behind instrument panel to left of steering column, Remove selector switch terminal block-to-lower end of steering column screws and secure block to one side. Remove steering column-to-instrument panel clamp, lower column slightly from car. Use suction gun to remove fluid from pump reservoir and place drain pan to catch oil from system. Disconnect pressure return hoses at power steering gear and drain steering gear by turning it to full travel in each direction. Raise car and use Tool 3590-E to remove pitman arm from sector shaft. Remove steering gear to frame screws and lower steering gear through linkage.

Installation - Work steering gear up through linkage into position on frame with shim between gear assembly and frame side member at rear bolt but do not tighten retaining screws. Line up master spline in steering gear shaft coupling with master spline in steering shaft and install steering column and wheel assembly, engaging dowel in instrument panel with hole in steering column. Install but do not tighten column bracket screws. Tighten steering gear bolts to 40-50 ft. lbs., then tighten steering column bracket screws to 10-13 ft lbs. Attach switch block to lower side of steering column and connect directional signal wires at connector. Turn steering wheel to both extremes while counting number of turns, then return wheel to center position (½ number of turns). Install pitman arm (large spline on sector shaft with wide groove in arm) and tighten nut to 120-130 ft. lbs. *CAUTION - DO NOT drive pitman arm on with a hammer.* Reinstall return and pressure lines, fill pump reservoir, start engine and turn steering wheel through several extreme right and left turns to bleed system. Refill reservoir. With engine running, pull required to turn wheels full right or left should be 3½-4½ lbs.

REMOVAL: Lincoln - Remove pressure and return lines from steering gear (raise lines to minimize fluid leakage) and remove power brake assembly. Remove steering shaft coupling bolts and remove pitman arm with Tool 3590-AA. Remove gear assembly-to-underbody rail bolts and remove gear from vehicle.

Installation - Place steering gear against side rail and tighten bolts to 40-50 ft. lbs. Install pitman arm with large spline on sector shaft aligning with large groove in arm and tighten nut to 120-130 ft. lbs. *CAUTION - DO NOT drive pitman arm on with a hammer.* Replace power brake assembly, assemble steering shaft coupling, pressure and return lines. Torque pressure line to 10-15 ft. lbs. and return line to 20-30 ft. lbs. Fill and bleed power brake and steering systems.

OVERHAUL

DISASSEMBLY: *NOTE* - Keep bench, tools and parts clean and DO NOT use magnetized tools.

1) Remove steering shaft coupling (support shaft while driving out pin to protect valve sleeve bearing) and drain fluid. On Edsel, place Tool 3524 on end of worm shaft (and spring scale on tool), then measure effort required to turn worm shaft from end of travel through center section It should require 1-1½ lbs. more effort through center position

2) Remove cylinder cap snap ring *(See "Tool Note" above)*, and cap. Remove cap "O" ring.

3) With gear housing in vise, install tool 3524 on worm shaft and turn worm shaft to bottom piston in housing then back off 2 turns (Edsel), 2 1/8 turns (Lincoln) to center gear.

4) With worm bearing preload and sector mesh adjusted correctly (see "Adjustments"), check backlash between sector gear and piston rack as follows Place dial indicator on center of piston, turn worm shaft to move piston .020" toward open end of bore and return piston until indicator returns to zero. *NOTE - DO NOT back up piston should indicator move past zero, but return to above step.* Push piston down (by hand) to bottom of travel and note indicator reading while holding piston under pressure. Backlash should not exceed .004". When backlash exceeds .004", replace piston with one having oversize gear rack.

5) Loosen sector shaft lock nut and adjusting screw. Remove housing cover screws, then tap lower end of shaft with lead hammer to remove sector shaft, cover, and gasket.

6) Slide cover to one side to release adjusting screw from shaft and remove adjusting screw

7) Use pry through sector shaft bore to remove piston from housing and remove piston "O" ring from bore.

8) Loosen valve sleeve locking screw and remove valve spool adjuster cap with Tool 3553-L and remove "O" ring from cap Remove thrust bearing locknut, control valve sleeve adjuster nut (Tool 3821), torsion bar and sleeve assembly (tap lower end of torsion bar with soft hammer) Remove sector shaft seal retaining ring with Tool 33621 and gear housing snap ring with Tool 1175-AE

Torsion Bar & Sleeve Disassembly: 1) Use cloth to clamp ball nut assembly in vise and remove valve spool sleeve from torsion bar assembly and remove "O" ring from sleeve. Remove valve spool adjuster lock nut, valve spool adjuster, and adjuster "O" ring.

CONTINUED ON NEXT PAGE

EDSEL & LINCOLN "TORSION BAR" POWER STEERING (Cont.)

2) Remove torsion bar, valve spool, and actuator from worm shaft by tapping end of bar with soft hammer. *CAUTION - Valv spool and actuator are spring loaded.*

3) Remove worm thrust bearing and cup from gear housing, then separate valve spool and actuator assembly from torsion bar by turning valve spool and actuator while holding torsion bar.

4) Use Tool 33621 to remove valve spool snap ring and remove actuator. Check ball nut assembly for binding or rough spots in the assembly. *CAUTION - DO NOT disass mbl th ball nut assembly unless check indicates binding or rough spots and DO NOT rotate ball nut against nd of worm shaft.*

Ball Nut Disass mbly - Remove ball nut guide retainer, ball guides, then turn nut over and remove balls by rotating worm shaft from side to side. *NOTE* - Keep balls in clean pan on clean cloth. Remove ball nut from worm shaft noting position of ball nut on worm shaft.

Cl aning & Insp cti n - Wash all parts in clean solvent and blow dry. Check worm, ball nut grooves, and all balls for wear or scoring. *NOTE - Worm and ball nut are servic d as matched assembly.* Inspect ball nut teeth for pitting, wear or scoring. Be sure ball return guides where balls enter and leave are not damaged.

Ball Nut R ass mbly - 1) Slide ball nut over worm for correct position and align ball return guide holes with worm groove. Drop exactly 31 balls (one circuit capacity) into both guide holes of one circuit while alternately turning worm in opposite directions. Fill circuit from bottom of one guide hole to bottom of other guide hole. The remaining balls should fill the return guide.

2) Coat groove of one half of return guide with clean solvent grease and place remaining balls in guide. Place other half of guide over balls.

3) While holding two halves together, push guide into guide holes in gear rack. Tap guide lightly with soft hammer as necessary to seat it. Fill second ball circuit in same manner and attach guide clamp with lockwasher and retaining screws.

Ste ring G ar H using Disassembly, Inspection, Reass mbly: Clean thoroughly with solvent and blow out all passages. Inspect housing for cracks or stripped threads and mating surfaces for burrs. Check fluid passages for obstructions or leakage and inspect housing bore. Replace housing if scored or worn. Check sector shaft bushings in housing for wear and replace as necessary.

1) Remove lower worm bearing cup and inspect for wear. Use Tool 3553-D to remove upper bushing. *NOTE* - Be sure jaws of tool are properly seated on edge of bushing.

2) Remove sector shaft lower bushings separately from each end of sector shaft housing with Tool 3553-A and 3553-C1 and C2 with small outside diameter of Tool 3553-C2 toward bushing to be removed. *NOTE* - Spread jaws of tool until they are properly seated on edge of bushing. To install upper bushing, place it on Tool 3353-F and drive into housing.

3) Install lower sector shaft bushing with Tool 3553-E2 and E1 and handle Tool 3553-B, then install lower worm bearing and cup in housing.

Sector Shaft & Piston Inspection: 1) - Replace sector shaft when worn, pitted, or scored.

2) End play of adjusting screw in slot in sector shaft should not exceed .002". Check with feeler gauge between head of screw and bottom of slot in shaft. Insert proper shim to correct end play (available in .063", .065", .067" and .069" sizes).

3) Cneck piston rack teeth for pitting, wear and scoring, then check piston for cracks. Check "O" ring grooves in piston rack bore, piston, and cylinder cover for burrs and nicks. Check cylinder cover for nicks.

Torsion Bar & Sleeve Reassembly: 1) - Inspect splines on torsion bar for nicks, pitting, wear or scoring. Replace torsion bar assembly when blind spline on torsion bar DOES NOT line up with punch mark on upper end of assembly (large splined end).

2) Place actuator on torsion bar with spring in place. Hold torsion bar and turn actuator. Spring should pop actuator off threads when released. Replace spring and check for burrs on gear teeth when spring does not pop off.

3) Torsion bar bearing should be free to rotate. If bearing is satisfactory replace oil seal. If not satisfactory, remove bearing and seal together with Tool 3583-J.

4) Use Tools 3583-J and 3583-J2 to install torsion bar bearing in sleeve and use same tools to install seal. Install snap ring and check bearing operation.

5) Lubricate parts with Auto. Trans. fluid and check fit of worm gear outer race to insure that it is a hand fit. Install bearing and race on worm shaft.

6) Place valve spool on actuator and secure with snap ring. Spool must operate freely.

7) Place torsion bar spring and actuator on torsion bar and turn shaft so that the two identifying punch marks are in line. Hold assembly together and insert torsion bar into worm (aligning blind spline on torsion bar with scribed line on end of worm). *NOTE* - Torsion bar assembly is installed properly when valve spool bottoms against upper bearing and cup.

8) Install new "O" ring on valve spool adjuster. Install adjuster on torsion bar but do not tighten. Install lock nut and lubricate lip of torsion bar seal with Auto. Trans. fluid.

9) Place Tool 3591-B on upper worm shaft and install valve sleeve over spool until worm gear upper race is seated in recess of sleeve. Install new "O" ring seal on sleeve.

REASSEMBLY: 1) Align slot in sleeve with lock screw in housing and install torsion bar and sleeve assembly in housing. Tap on sleeve until it bottoms, then tighten lock screw to 15-20 ft. lbs. *NOTE* - When properly installed, lock screw and brass washer will be seated against housing.

2) Install pre-load adjusting nut and lock nut, then place Tool 3524 on lower shaft and check worm bearing preload. Adjust to½-2/3 lbs. on spring scale. *CAUTION* - Final adjustment must always be made on a tightening stroke.

3) Install spool valve centering wrench Tool 3553-K on valve spool adjuster and center valve spool until only "valley" between lands can be seen through pressure port. Hold torsion bar with Tool 3524 while turning centering wrench. Lock centering screw with locknut. *NOTE* - This is preliminary adjustment, final adjustment made on car.

4) Center ball nut with centerline of sector shaft opening and install new "O" ring in piston rack bore of housing and lubricate.

5) Use hand hone to carefully hone all edges of piston rack teeth to save damage to piston rack bore "O" ring during installation.

6) Install new "O" ring on piston and install piston in housing, then align center rack teeth with sector bore in housing (third groove in piston rack).

7) Grease splines of sector shaft and install it making sure that sector shaft is centered by installing Tool 3524 on torsion bar and rotating worm shaft. There should be at least four (4) turns from one stop to the other. Reinstall sector shaft when minimum turns not possible.

8) Use Tool 3591-A to install sector shaft seal with seal protector Tool 3576-J, and install snap ring.

9) Use proper shim and install sector shaft adjusting screw in slot in sector shaft and place housing cover (with new gasket in place) over adjusting screw. Turn screw until cover is seated. Tighten cover screws to 15-20 ft. lbs.

10) Adjust sector shaft (see "Adjustments" above) and check piston rack backlash. Install new "O" ring on cylinder end cap, install cap and secure with snap ring.

HYDRAULIC PUMP

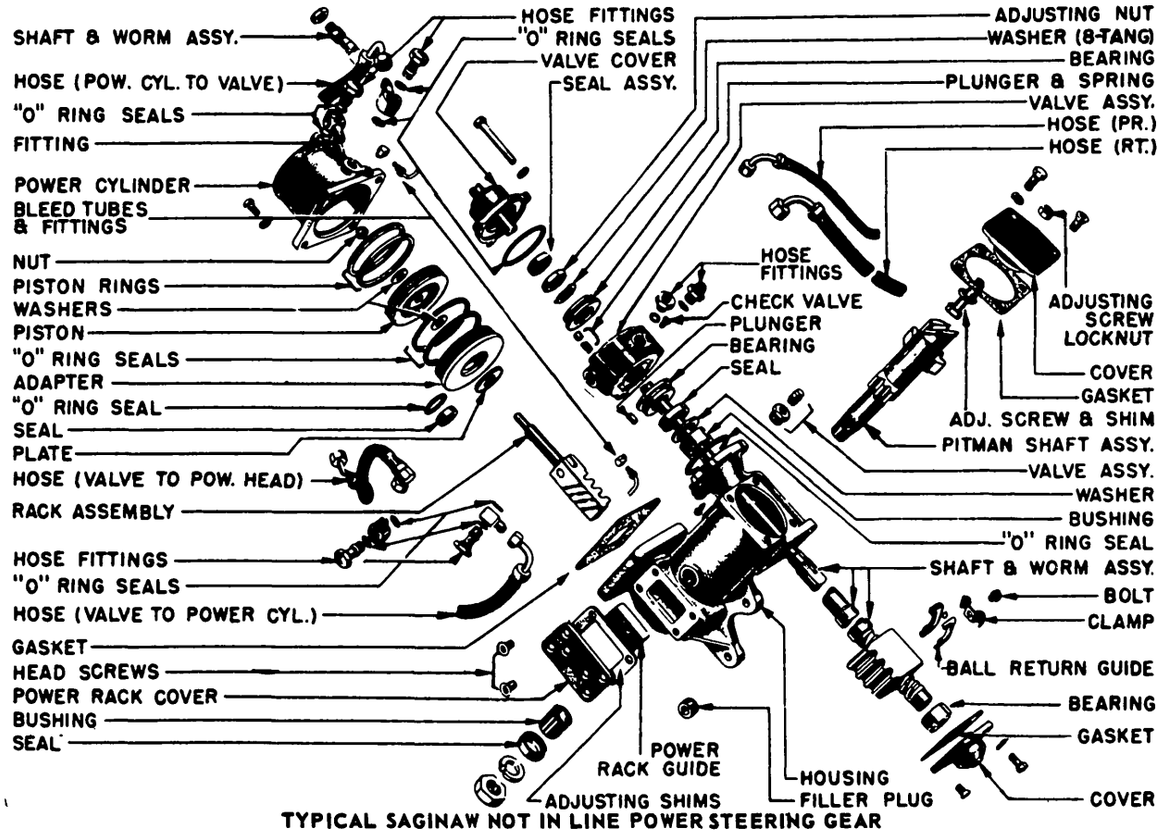
HYDRAULIC PUMPS: Various types used as follows:

Eaton Roller Type (Belt Driven) - Used on 1958-Early 1959 Lincoln and on some 1958 Edsel model. *See "Eaton Roller Type Power Steering Pumps".*

Eaton Roller Type (Crankshaft Mounted) - Used on Late 1960 Lincoln. *See "Eaton Roller Type (Crankshaft Mounted)Power Steering Pumps".*

Van Typ (Crankshaft Mounted) - Used on Late 1959 & Early 1960 Lincoln and on some 1958 Edsel models. *See "Edsel, Lincoln, Mercury (Crankshaft Mounted) Power Steering Pumps.*

SAGINAW (NOT IN LINE)



Buick (1954-55)
Cadillac (1954-55)
Chevrolet (1954)
Lincoln (1954-55)
Oldsmobile (1954-55)
Packard (1957-58)
Pontiac (1954-55)
Studebaker (1954-Early 1959)

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 VICKERS PUMP FRONT SHAFT SEAL PRODUCTION CHANGE (To Reduce Leaks):* Front shaft seal, Part No. 5681410, replaces Vickers Seal, Part No. 5665833, used in early production. New seal has greater lip pressure than previous one. A hardened shaft, Part No. 5681681, **must** be used with new seal and may be used with old type seal. New shaft and seal are carried in package, Part No. 5681951. Pumps with new seal have smaller reservoir and are marked with daub of green paint on front of hub body instead of yellow daub at same place on earlier pumps. New hardened shaft is identified by a daub of green paint on threaded end of shaft or by a machined groove on the .75" diameter adjacent to splined end of shaft. To service pumps built after change use Master Kit, Part No. 5681964, and for those built prior to change use Master Kit, Part No. 5682130 (includes new shaft and seal).

►*1954 CADILLAC "CHATTER" CORRECTION:* Some cases of chatter (not chuckle) may be noted on cars built previous to Engine No. 01688 when making light turns or parking. Noise is particularly noticeable after reversing direction of steering wheel rotation when backing into a parking space. To correct, replace valve body assembly.

►*1954 CHEVROLET LEAD OR WANDER CORRECTION:* Cenerally can be attributed to improper assembly of valve body assembly or improper usage of "O" ring seals. Trouble in valve body assembly can be checked by end motion of steering shaft with respect to its housing while oscillating pitman arm between right and left turn positions. Measurement in excess of .002" indicates that valve has excessive free movement in the valve body and can be allowing fluid to pass to power cylinder. If in excess of .002" check valve spool for proper installation and check for proper "O" ring usage. Turn valve spool over and recheck. If endplay still excessive, replace valve body assembly.

TYPICAL SAGINAW NOT IN LINE POWER STEERING GEAR

►*1954 PONTIAC BELT ADJUSTMENT CORRECTION:* In some cases it is not possible to adjust belt tension as specified due to interference between pump body and bracket. If belt is in good condition, place flat washer on each of three mounting studs, under bracket, to raise bracket and pump.

►*1955 BUICK STEERING SHAFT BUSHING PRODUCTION CHANGE & STEERING SHAFT RATTLE CORRECTION:* A new nylon, spring loaded, steering shaft upper bearing, Part No. 1169623, is used in production and is available for service replacement. Replace the former fabric bearing, Part No. 5664839 to eliminate steering shaft rattle and chucking noises.

►*1955 PONTIAC POWER ST. VALVE CENTERING SPRINGS & PLUNGER PRODUCTION CHANGE:* Early type springs are shorter (.660") and are plated. Plungers are grooved. Later type springs (.760") are plain steel (not plated), and plungers do not have a groove. These parts are interchangeable in complete sets only.

►*1956 STUDEBAKER & PACKARD POWER STEERING GEAR NOISE CORRECTION:* If excessive gear "chuckle" is evident, check to see if "T" mark on steering gear flange is properly located in relation to mid-position or "high point" of gear. If this condition exists, then pitman arm will not be centered and the left tie-rod will be short and the right tie-rod will be longer. To correct, center front wheels, then remove steering wheel and reposition it 90° clockwise in relation to existing mark. Install retaining nut and horn ring, then turn steering wheel back to normal horizontal position which should place gear on "high point". This should also center steering bellcrank. Readjust tie-rods to obtain a straight ahead front wheel setting and adjust toe-in.

►*1957-58 STUDEBAKER & PACKARD STEERING POST FLANGE PIN CHANGE:* To improve flange fit on steering post, install flange pin, Part No. 1547173 and flange, Part No. 533251 as follows: Remove steering wheel, post and jacket and remove old flange. Remove post from jacket assembly, then assemble old flange on post (with new lower insulator and with "T" marks aligned), adding sufficient washers so nuts can be tightened. Position assembly in drill press vise or "V" blocks, then align old flange on post by centering drill through flange and post. Lock post in vise or "V" blocks, then remove drill and install new flange with insulator. Drill a 3/16" hole through new flange.

DESCRIPTION

DESCRIPTION: Power steering unit consists of a conventional Saginaw Recirculating Ball Bearing Worm & Nut type steering gear with an additional hydraulic power and control assembly. Hydraulic power assist is effective when a pull of 3-4 lbs. or greater is exerted at steering gear rim.

ADJUSTMENT

►*ADJUSTMENT CAUTION: When ver hydraulic system is disturb d by disconn cting lin s, r m val or installation of units, tc., hydraulic system must be bl d to remov air. S "Bl eding Hydraulic System" bel w.*

C NTINUED N NEXT PA E

SAGINAW (NOT IN LINE) (C ntinu d)

1954 MODELS

►*LINCOLN ADJUSTMENT NOTE:* All adjustments of steering gear are to be made with unit removed from vehicle and disassembled. *See Overhaul.*

►*OLDSMOBILE & STUDEBAKER ADJUSTMENT NOTE:* All adjustments of steering gear, except high spot adjustment, are to be made with unit out of car. *See Overhaul.*

Adjustm nts n Car: *CAUTION–BEFORE MAKING ADJUSTMENTS,* disconnect drag link at pitman arm, check tightness of pitman arm nut, check steering gear for binding by turning steering wheel slowly from one end position to the other *(CAUTION–*Do not turn steering gear hard against stops in end position to avoid damage to ball nut mechanism). Correct any binding due to misalignment before attempting to adjust steering gear.

Cadillac Alignm nt N te–Check alignment as follows: Loosen all three gear-to-frame mounting screws, tighten front screw only, check clearance between housing and frame at rear mounting screws and shim as required to fill the gap. If no clearance noted at rear screws, loosen front screw and tighten rear screws. Check clearance at front screw and shim as required to fill the gap. Tighten all three screws to 40-50 ft. lbs. torque. Recheck steering gear for freedom from binding.

Off-C nt r Pre-l ad Ch ck (Unit on Car)– Proceed as follows:

Buick–Disconnect pitman arm from intermediate tie rod, then loosen four corner bolts of the power rack guide cover about 1/2 turn or just enough to assure lash between power rack and pitman shaft sector (NOTE–If bolts loosened too much, rack will bind on sector teeth). Turn steering wheel 2-3/4 turns from either extreme position to center ball nut on the central "high point" of pitman shaft sector (At this position center spoke of wheel should be straight down). Turn pitman shaft adjusting screw clockwise until lash between pitman shaft sector and ball nut is just removed (check by working pitman arm), then tighten locknut. Turn steering wheel two turns either way from central position and check pull with scale at rim of wheel and pulling at 90° to spoke. This should be 3/8-3/4 lb. (1952-53), 1/2-1 lb. (1954).

Cadillac–Disconnect drag link at pitman arm. Back off power rack and pitman shaft adjusting screws at least 1/2 turn. Using spring scale, check "off-center" pull through at rim of steering wheel. This should be 7/8-1 1/8 lbs. (1952-53), 3/8-3/4 lb. (1954).

►*NOTE–*If readings outside above limits it will be necessary to remove unit from car.

Pitman Shaft Adjustm nts–*Two separate adjustments required as f ll ws:*

Oldsm bil & P ntiac Adjustment N te–Special "offset" screwdriver required for this adjustment.

Stud bak r Adjustm nt N t –Steering Gear Adjusting Tool J-5563 is used in lieu of steering wheel for pitman shaft adjustment.

1) High Sp t r Pitman Shaft-t -Ball Nut Lash (Pitman Shaft Endplay)–Loosen power rack cover bolts. Turn steering wheel slowly through its full range to check for freedom of movement, then turn wheel back to midway position to center ball nut on central high point of pitman shaft. Turn steering wheel shaft 45° right or left of center. Place spring scale on spoke of wheel at rim and pull on scale, at a 90° angle to spoke, to turn steering wheel. Adjust pitman shaft adjusting screw so that pull on 9" radius to turn wheel smoothly over center high spot is:

Buick–1/2-3/4 lb. **higher** than in "Off-Center Pre-Load Check".

Cadillac–1/2-1 lb. **higher** than in "Off-Center Pre-Load Check".

Chevrolet–1 1/8–1 1/2 lbs.

Oldsmobile–1 3/4 lbs. maximum.

Pontiac–1-1 1/2 lbs.

Studebaker–1/2-1 lb.

Note–Lincoln "High Spot" adjustment included in overhaul.

Record reading for Power Rack Guide adjustment.

2) Pitman Shaft-to-Power Rack Lash (Power Rack Guide Adjustment)–Tighten power rack cover bolts. Turn steering wheel slowly through its full range to check for freedom of movement, then turn wheel back to center position. Turn steering wheel shaft 45° right or left of center. Place spring scale on spoke of wheel at rim and pull on scale, at a 90° angle to spoke, to turn steering wheel. If power rack cover shims have been selected properly there will be a preload in addition to over-center or pitman shaft adjustment when column shaft is rotated past center high spot as follows:

Buick–1/4-1/2 lb. higher than in 1) or 1 1/4–2 1/4 lbs.

Cadillac–1/8-1/4 lb. higher than in 1) or 1 1/4–2 lbs.

Chevrolet–1/8 lb.

Pontiac–No increase.

Note–Lincoln, Oldsmobile, and Studebaker "Power Rack Guide Adjustment" included in overhaul.

If adjustment is above or below that specified, add or subtract shims. Subtracting shims will decrease reading and adding shims will increase reading.

NOTE–Add or subtract one .003" shim (.003", .005", and .010" available) at a time until desired reading is reached. After all adjustments made, there should be no perceptible backlash in sector shaft when column shaft is rotated 30° either side of center. Recheck of over-center adjustment after complete assembly of column jacket, gear one turn off center, and pitman arm disconnected, should give following minimum to maximum readings:

Buick–1 1/8–2 lbs.

Cadillac–1-2 lbs.

Chevrolet–1-5/8 lbs. maximum.

Pontiac–1–1 1/2 lbs.

Worm Thrust Bearing Adjustment–This adjustment normally made when assembling steering gear and **can nly b mad with st ring gear ut f car.** If adjustment required in service, remove steering gear from car. *For adjustm nt proc dur s e St ring Gear Ov rhaul (following).*

PUMP DRIVE BELT ADJUSTMENT: Adjust as follows:

Buick - Belt should have 3/8" deflection with thumb pressure applied midway between pulleys. To adjust, loosen pump mounting bolts and shift pump horizontally (bolt holes in bracket slotted).

Cadillac - If belt squeals on hard turns, belt is too loose. Adjust by loosening pump to bracket screws and moving pump outward to torque wrench reading of 13-15 ft. lbs. Tighten screws to 25-29 ft. lbs.

Chevrolet - Loosen inner bracket to pump and outer bracket to pump fixed mounting bolts. Insert Belt Tension Adjusting Tool J-5470 between pulley and pump with inner end of tool resting under pulley hub and not in tool over head of outer fixed mounting bolt. Pull outward on torque wrench until a torque of 14 ft. lbs. is obtained. Tighten mounting bolt at slotted hole, remove tool and torque wrench, then tighten fixed mounting bolt.

Lincoln - Lift up on pulley to tighten belt. Do not lift on reservoir. Belt tension should have 5-7 lbs. pull at ¼" deflection. Torque 35-50 ft. lbs.

Oldsmobile - Use Belt Tension Adjusting Tool J-5192 and Torque Wrench. Loosen inner and outer bracket-to-pump mounting screws (inner screw hole slotted), insert adjusting tool between pulley and pump with inner end of tool under smaller diameter of pulley hub and notch in tool over head of outer mounting screw. Pull outward on torque wrench until reading of 30 ft. lbs. (new belt), 20 ft. lbs. (broken-in belt) obtained, tighten mounting screws before slacking off on wrench. This setting corresponds to belt deflection of 7/8" with 25 lbs. pressure midway between pump and fan pulleys.

Pontiac - Loosen pump to bracket attaching bolts two full turns so pump falls free of own weight. Place pump belt tightener J-5452 (Eaton type pump); J-5574 (Vickers type pump) over head of upper bolt so that curved portion of tool fits under pulley. Using ½" drive 0-100 ft. lbs. torque wrench perpendicular to tool, apply torque of 43-45 ft. lbs. (Eaton Pump); 58-65 ft. lbs. (Vickers Pump - New belt); 51-53 ft. lbs. (Vickers Pump - Used belt). Tighten lower pump to bracket attaching bolt. Remove tool and tighten upper attaching bolt.

Studebaker - Belt deflection should be 1/4-3/8" with pull of four lbs. at point midway between pump and crankshaft pulleys. Slots provided at mounting screws in bracket to permit shifting pump body to secure proper belt tension.

1955 & LATER MODELS

ADJUSTMENT: (ON CAR)–Before making adjustments, disconnect drag link at pitman arm, check tightness of pitman arm nut, and check steering gear for binding by turning steering wheel slowly from extreme right to extreme left *(CAUTION–*Do not turn steering wheel hard against stops in end position to avoid damage to the assembly). Correct any binding due to misalignment before making adjustments. Loosen four corner bolts of power rack guide cover about one-half turn or just enough for lash between rack and sector.

►*BLEEDING HYDRAULIC SYSTEM NOTE: Syst m must be bled for mov air wh n v r lines ar disconn cted r units r moved and install d.*

CONTINUED ON NEXT PAGE

SAGINAW (NOT IN LINE) (C ntinu d)

High Spot Adjustment (Pitman Shaft Sector-to-Ball Nut Lash): As follows:

Buick—Turn wheel to extreme right or left position. Attach scale J-544-A to a spoke at rim of wheel and, while pulling scale at 90° to spoke, check pull required to turn wheel steadily in the range where lash normally exists between pitman shaft sector and ball nut (lash range is 1/8 turn of steering wheel from either extreme position). Reading on scale should be between 1/2 and 7/8 lbs. (If not within these limits, check steering column alignment at frame mounting bolts, faulty steering shaft upper bearing, or worm thrust bearing adjustment). If reading within limits, turn steering wheel 2¾ turns from either extreme position to center ball nut on "high-spot" of sector (center spoke of wheel should be straight down). Turn pitman shaft adjusting screw clockwise until lash between sector and ball nut is removed (check by working pitman arm), then tighten locknut. Turn steering wheel 2 turns in either direction from center position and check pull with scale. This should be between 1/2 and 7/8 lb., record this reading for reference. Turn steering wheel back to near center position and check pull required to turn wheel through "high spot". Turn pitman adjusting screw clockwise as required to obtain a scale reading ½-¾ lb. higher than that obtained at end position of travel, after locknut tightened. Record this latest scale reading for "Power Rack Adjustment" reference, below.

Cadillac—Check flexible steering shaft coupling for distortion and correct as necessary. Using spring scale J-544-A, check the "off-center" pull through at rim of steering wheel which should be 3/8 to 3/4 lb. (If reading not within these limits, remove steering gear and check thrust bearing locknut torque which should be 30 ft. lbs.). Check for binding or rough bearings in upper and lower thrust bearing retainers. Adjust pitman shaft endplay screw until pull through center is ½-1 lb. greater than pull at one full turn off center.

Lincoln—Adjustments on car are not recommended, and should be performed when steering gear is removed for overhaul or when being installed.

Oldsmobile—Turn steering wheel through full range (5½ turns), to check for free action; then, turn wheel back one full turn from right or left position. This positions wheel in middle of lash range. Attach spring scale J-544-A to spoke of wheel at the rim, and while pulling on scale steadily at 90° to spoke, observe amount of pull required to turn wheel through lash range (record this reading for reference). Turn wheel to center position (2¾ turns from full right or full left) and observe the amount of pull required to turn wheel through the "high spot" (center) range. This should be 5/8 lb. more than the amount recorded in lash range. Adjust pitman shaft adjusting screw to obtain the correct amount of pull at the "high-spot" and tighten adjusting screw locknut.

P ntiac—Loosen pitman shaft adjusting screw locknut and back off adjusting screw a few turns, using an offset screwdriver. With steering gear on "high-spot" (center position), adjust pitman shaft thrust screw so that pulling on steering wheel rim through a 3" arc using J-544-A spring scale, is 1-1¾ lbs., through the center "high-spot". Tighten locknut and recheck pull through "high-spot".

Studebaker—The "high -spot" and power rack adjustments should be made while steering unit is out of car, although minor changes can be made in "high-spot" adjustment with the unit installed.

Power Rack Guide Adjustment: This adjustment must be made after "High Spot" Adjustment completed.

Buick—Tighten the four power rack guide cover bolts and recheck pull through the "high spot". The scale reading should be ¼ to ½ lb. higher than the final reading taken in "High Spot" Adjustment (above), or between 1 1/8 & 2 lbs. If reading is not within these limits, add or remove shims as required to obtain the specified pull through the "high spot". Guide cover shims are available in .003" and .005" thicknesses.

Cadillac—Using tool J-5648, tighten the power rack adjusting screw so that "high spot" pull through (see above), is 1/8 to 1/4 lb. higher than that obtained in "High Spot" Adjustment. This should be measured at rim of wheel through an arc not exceeding 3".

Lincoln—Adjustments on car are not recommended, and should be performed when steering gear is removed for overhaul or when being installed.

Oldsmobile—Tighten power rack guide cover bolts evenly, being sure that bolt threads do not pick up shims when tightening cover to housing. Attach spring scale to wheel rim and check pull through "high spot". If pull is increased over the final reading taken in "High Spot" Adjustment (above), add shims of .003" thickness, one at a time until pull decreased to original reading. If pull remains the same as final reading, remove shims of .003" thickness, one at a time, until pull is increased above original amount, then add one .003" shim. Recheck pull through the "no lash" range which should not be more than 1¼ lbs. Pull required in pull through "High spot" should not be greater than 1¾ lbs.

Pontiac—Tighten four power rack guide cover bolts evenly. Recheck pull through "high spot" position which should be 1½ lbs. maximum. If "high spot" pull increased after power rack guide cover bolts tightened. above the maximum (1½ lbs.), add .003" shims under cover until last shim added decreases the load. If pull through "high spot" remains the same after cover bolts tightened, remove .003" shims until load increases above that obtained in final check of "High Spot" Adjustment. Then add one .003" shim.

Studebaker—The "high spot" and power rack adjustments should be made while steering unit is out of car.

Worm Thrust Bearing Adjustment: This adjustment made with steering gear out of car. If adjustment required in service, remove steering gear. See "Steering Gear Overhaul" below, for adjustment procedure.

Pump Drive Belt Adjustment: Proceed as follows:

Buick—Adjust belt tension so that pulley will slip in belt when 40-45 ft. lbs. (new belt), 30-35 ft. lbs. (used belt), is applied to pulley nut with a torque wrench.

Cadillac—Loosen pump to mounting bracket screws and move pump outward until belt is tight. With shift lever in "N" race engine while turning steering wheel. If belt squeals, it is too loose and must be retightened.

Linc ln—Belt tension should be 5-7 lbs. pull with ¼" belt deflection.

Oldsmobile—Loosen pump to bracket attaching bolts and place tool J-5398 under pump pulley and over attaching bolts, With torque wrench, adjust drive belt tension to 30 ft. lbs. This adjustment corresponds to a belt deflection of 7/8" with 25 lbs. pull applied midway between pump pulley and fan.

Pontiac—Loosen pump to bracket bolts two full turns so pump falls of its own weight. Place pump belt tightener J-5574, over head of hinge bolt, and using a torque wrench perpendicular to tool, tighten belt to 58-65 ft. lbs. (new), 51-53 ft. lbs. (used). Tighten clamp bolt.

Studebaker—With spring scale at right angles to belt, pull on scale should be 4 lbs., with a belt deflection of 1/4" to 3/8". Slots are provided at mounting bracket screws in bracket to permit shifting pump body for proper tension.

HYDRAULIC PRESSURE TESTS

Disconnect hose at lower pump union (nearest engine). Install Gauge J-5176 (Lincoln Gauge No. 3500), with gauge valve closed. Connect hose to fitting on valve side of gauge. **Open gaug valv** and run engine at idle speed. Test as follows:

1) With gauge valve open and engine idling, turn steering wheel through entire travel from one end position to the other with the wheels on the ground *(CAUTION—* Do not hold steering wheel in extreme position for extended period). Oil pressure on gauge should not be less than indicated in table below. If pressure is less than indicated in table, test as outlined in **(2)** below.

Car	Engin RPM	①Pump Pressur
Buick	450	700 lbs.
Cadillac (1954-55)	400	900 lbs.
Chevrolet	475	750 lbs.
Lincoln (1954-55)	425-450	700 - 900 lbs.
Oldsmobile	400	650 lbs.
Pontiac	375	650 lbs.

①—Maximum pressure should not be less than lowest indicated pressure.

2) If pressure low in test above, slowly close gauge valve and make quick test of pump pressure *(CAUTION—* Do not leave valve closed more than 15 seconds). If pressure increases to, or is greater than the pressures indicated in table (above), pump is alright and trouble is in steering gear or in oil lines. If pressure equally low in both tests (or not more than 50 lbs. increase in test **(2)**, trouble is in oil pump. If pressure increases more than 50 lbs. in test **(2)** but is still below normal, both pump and steering gear or oil lines are faulty.

TROUBLE SHOOTING

If operation not satisfactory, check as follows:

HARD STEERING (Particularly When Parking): Check to make certain that hard steering exists by measuring steering wheel pull under extreme conditions as follows: With car parked, apply brakes, idle engine, turn steering wheel from side to side to bring oil temperature up to 170°F. (similar to condition existing after excessive turning or on hot days). Use 15 lb.

CONTINUED ON NEXT PAGE

SAGINAW (NOT IN LINE) (C ntinu d)

spring scale (Tool J-5178) hooked to wheel rim at spoke to check pull required to rotate wheel steadily (measure pull at 90° to spoke). If pull exceeds 10 lbs., check following causes:

1) Pump drive belt loose or pump defective. Adjust drive belt and test pump pressure. See Testing Hydraulic Oil Pressure.
2) Low Oil Level in Reservoir. Check and fill reservoir to proper level. If oil level low, check entire system for evidence of leakage.
3) Air in Hydraulic System (may be noted by noisy pump action). Tighten valve cover screws and all hydraulic line connections. Bleed system.
4) Steering gear not properly lubricated or adjustments too tight. See Lubrication and Adjustment.
5) Steering tube misaligned or tight upper bearing. See Steering Gear alignment (under Adjustment).
6) Linkage too tight, bent, or misaligned.
7) Tires under-inflated.
8) Low oil pressure. See Testing Hydraulic Oil Pressure.

EXCESSIVE PLAY OR LOOSENESS (May cause Front Wh l Shimmy r wh el kickback):

1) Excessive lash in steering gear (between pitman shaft gear sector and ball nut or power rack) or in steering linkage. See Adjustment.
2) Loose worm thrust bearing adjustment (see Adjustment) or valve spool sticking in housing.
3) Air in hydraulic system (may be noted by noisy pump action). Tighten valve cover screws and all hydraulic line connections. Bleed system.

POOR CENTERING OF STEERING WHEEL OR RECOVERY FROM TURNS:

1) Binding of steering shaft due to misalignment or tight bearings. Check alignment and adjustments.
2) Valve spool sticking in valve housing or defective valve centering plunger springs.
3) One front tire under-inflated.

STEERING GEAR NOISY:

1) Loose pitman shaft adjustments (excessive lash at ball nut or power rack). See Adjustment.
2) Loose worm thrust bearing. See Adjustment.
3) Loose power piston-to-power rack pin.
4) Steering gear mounting loose (noisy on turns).

HYDRAULIC PUMP NOISY:

1) Air in system due to low oil level, loose intake hose connections, defective shaft or steering gear seals.
2) Pump drive belt too tight. See Belt Adjustment.
3) Oil hoses grounded against engine. Check and reroute hoses to provide clearance.
4) Reservoir air vent clogged, clogged intake line or filter, sludge or dirt in pump, oil too heavy. Clean out pump and reservoir and refill with correct oil.
5) Pump bearings, shaft, or other parts worn. Pump vanes sticking (Vickers Pump).
6) Relief valve chattering. Check for sticking valve, clean and free up valve.

LOW OIL PRESSURE: S T sting (f ll wing).

1) Drive belt loose or worn. See Belt Adjustment.
2) Oil level too low or wrong type oil (too light).
3) Pump worn or defective. Pump relief valve stuck open or spring weak. Flow control valve stuck open.
4) Oil filter clogged (cars with Eaton pump).
5) Internal or external oil leaks (following).

OIL LEAKAGE:

1) Defective "O" ring seals due to over-torquing, burrs in recesses, cocked seals, unclean bores, seals not protected from threads on shafts, sharp edges.
2) Loose connections or worn hoses.
3) Oil pump shaft seal installed backwards (install with two holes in seal casing toward front or outside of pump (pulley end).
4) Improper installation of plug and "O" ring (Vickers Pump). Must be installed to pump cover flow control valve from rear (chamfer end) until end of plug is just past snap ring groove.
5) Hydraulic oil leaking into steering gear housing; upper housing seal or cylinder adapter seal (piston rod seal) leaking.

LUBRICATION

Power Steering Hydraulic System: (Checking Fluid Level)—Check at 1000 mile intervals (2000 miles on Cadillac, 5000 miles on Studebaker).

Buick—Thoroughly clean area around filler plug in top of reservoir, remove filler plug (has dipstick underneath), insert dipstick in reservoir with **plug seated on edge of filler opening,** add oil as required to bring level up to mark on dipstick.

Cadillac, Chevrolet, Oldsmobile, Pontiac - Clean reservoir cover area, remove cover and gasket. Oil level should be at oil level mark on side of reservoir (1" below top edge of reservoir), Add oil as required. Torque cover screws to 20 ft. lbs. (On Pontiac replace cover and retaining ring).

Lincoln—With engine off, remove reservoir dipstick by turning counter-clockwise and pulling out. Level of fluid should be to the line marked "full" on the stick. *Do not overfill.*

Studebaker—Maintain fluid level at mark indicated on side of reservoir.

Recommended Oil—Use same oil as used in the automatic transmission on the car (Dynaflow Drive Fluid, Hydra-Matic Drive Fluid, or Automatic Transmission Fluid Type A with AQ-ATF No.).

Steering Gear (Worm & Ball Nut): Check at 1000 mile intervals (2000 on Cadillac, 5000 on Studebaker). Maintain lubricant level at filler plug hole. **Do not** use pressure gun to add lubricant (will damage worm and power piston rod seals). Use lubricants:

Buick & Studebaker—Multipurpose gear lubricant SAE 90 (same as for synchro-mesh transmission).

Lincoln—Ford Motor Company Specification M-4738 **or its absolute equivalent.**

Others—Approved steering gear lubricant.

BLEEDING HYDRAULIC SYSTEM: *Required whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units, etc.).*

Buick—Fill reservoir to proper level (see Lubrication). On cars with Vickers (vane type) pump, remove pipe plug from top of pump manifold until oil begins to flow from this opening, then install plug just tight enough to prevent oil flowing out. Allow car to stand for 5 minutes. Start engine and run at approximately 1000 RPM for 2-3 minutes, then turn steering wheel from wheel from left to right extreme position to work air out of power cylinder. Repeat as necessary until all air worked out (pump will quiet down as air removed). Tighten plug in pump manifold, recheck oil level. Road test car with some parking and high speed driving, if possible.

Cadillac, Chevrolet, Oldsmobile, Pontiac - Fill reservoir. Let car stand for two minutes. Crank engine with ignition off and turn steering wheel at the same time to eliminate air pockets from power cylinder while maintaining oil level in reservoir. Start engine and run at idle speed for 2 minutes. Check oil level and inspect entire system for leaks. Increase engine speed to 1500 RPM and run it at this speed until air bubbles cease to appear in reservoir (turn wheels from side to side to assist process, lightly contacting stops). Recheck oil level and refill as required.

Lincoln—Fill oil reservoir to proper level (see Lubrication). Start engine and run at idle speed for two minutes. Recheck fluid level and inspect hoses and connections for leaks. Increase engine speed to 1000 RPM and turn wheels from right to left five or six times. DO NOT HIT STOPS. Recheck for leaks. Check oil level and refill as required.

Oldsmobile—Fill reservoir to proper level and maintain level during bleeding operation. Run engine at idle speed for 30 seconds, then increase speed to 1500 RPM for 1 minute. Raise front end of car and rotate steering wheel through its full travel several times to eliminate air from system. Recheck fluid level in reservoir.

REMOVAL & INSTALLATION

1954-55 BUICK

REMOVAL: Remove the battery and shield. Disconnect pressure and return line hoses from hydraulic pump and immediately install shipping caps on pump fittings to retain oil in pump. Drain hoses and install plugs in hose ends. Disconnect transmission shift rod from control shaft lower lever. On synchro-mesh cars only, remove selector lever from clamp on jacket by removing retainer and spring washer. Loosen bolt in clamp which secures column jacket to short tube in gear housing. Move front seal all the way back. Disconnect and remove horn cable connector from steering column jacket. On Dynaflow cars, disconnect wires from neutral safety switch and remove speed ratio dial light bulb holder from support on steering column jacket. On all cars, remove signal switch wires from fuse block under cowl. Cover steering column jacket with masking tape to prevent damage to finish. Remove steering wheel and upper bearing spring and spring seats. Cover the horn contact and threaded end of steering shaft with masking tape. Remove signal switch and transmission shift control levers. Detach the rubber insulator retainer from dash mat and pull it up about a foot on column jacket. Remove jute column pad. Measure vertical clearance between column jacket and lower surface of instrument panel and record this dimension so column can be installed in same position. Remove bolts hold-

CONTINUED ON NEXT PAGE

SAGINAW (NOT IN LINE) (Continued)

ing cap to steering column bracket and disconnect bracket from instrument panel, then pull upward on column jacket to free it from steering gear. Remove cranking motor splash pan from car frame. Remove steering gear to frame lower bolts and clamps, then loosen upper bolts enough so that gear can be tilted sideways to provide room for pitman arm puller. Remove pitman arm. With another man inside the car to guide column and prevent damage, carefully lift steering gear assembly up and forward out of engine compartment, leaving column jacket assembly in car.

INSTALLATION: Reverse the removal procedure and note the following: When installing column jacket assembly over steering shaft, place Bearing Protector J-5159 over serrated end of shaft to avoid damage to shaft upper bearing in jacket (slot in lower end of jacket must engage dowel pin in hydraulic valve cover). When mounting the gear and jacket assembly in brackets, make certain that column is properly positioned at instrument panel and tighten column bracket before tightening gear housing to frame, then check for bind as follows: Temporarily install steering wheel and use scale J-544-A to check pull required to turn wheel steadily through high point or no lash range. The pull should not be more than ¼ lb. more than before installation. If greater, check upper bearing in jacket. Connect pressure hose to lower union on pump, and return line hose to upper union.

STEERING WHEEL & HORN BUTTON REMOVAL: On solid spoke wheel, pry out horn button cap, remove contact cup, spring and contact plate (attached to wheel hub by three screws and spacer bushing). On Flexible wheel, pry off monogram and bezel assembly and remove horn operating wheel (attached by three screws). On all models, set direction signal in "off" position, then flatten steering wheel nut lockwasher tab and back off nut several turns, but do not remove nut. Use Puller J-1566 and adapter to pull wheel back to nut. *NOTE - If wheel hub is tight on shaft, apply moderate strain with puller, then tap end of puller screw to break hub loose from shaft.* To install wheel, reverse removal procedure.

1954 CADILLAC

REMOVAL: Place front of car on jack stands, then remove steering wheel (see below) and steering column upper and lower covers. Remove screws in support bracket at instrument panel and screws attaching horn contact assembly to jacket, then remove screws in column cover on toeboard. Remove heater blower motor and remove flexible air intake hose. Disconnect hoses at steering gear and plug all openings. Loosen steering column lower jacket clamp, then disconnect connecting rod at pitman arm. Remove left exhaust pipe at manifold, then remove three bolts attaching steering to frame side rail. *CAUTION - Save all shims found at these mounting bolts as they will be required when gear installed.* Carefully slide gear down and out of upper jacket and remove assembly from car. *CAUTION - Be very careful not to damage upper rubber bearing.*

INSTALLATION: Reverse removal procedure.

STEERING WHEEL & HORN BUTTON REMOVAL: Disconnect horn wire from horn contact assembly on upper steering cover, then depress horn button and turn counterclockwise to release locking ears. Remove button assembly and horn button spring. Remove steering wheel hub nut, then remove horn ring retainer, cushion and horn ring. Mark steering wheel hub and shaft for correction installation, then use Puller J-1859 and remove wheel. To install, reverse removal procedure and note the following: Tighten wheel hub nut to 45-50 ft. lbs. Measure gap between bottom edge of horn ring and upper edge of direction signal switch carrier and slide steering jacket up or down to secure 3/16" gap with horn button in released position.

1955 CADILLAC

REMOVAL: (Gear Assembly)—Disconnect hoses from valve body on gear housing. Cap ends of hose to prevent loss of oil. Remove return port (large) fitting from valve body. Raise front end of car and place jack stands near outer ends of lower suspension arms. Disconnect pitman arm from drag link. Remove lower flange to coupling screws. *(NOTE*—Scribe marks on coupling and flange to assure correct positioning of steering wheel at assembly). Remove gear housing to frame side bar screws and remove gear housing.

INSTALLATION: (Gear Assembly)—Place assembly on frame side bar, guiding the lower flange onto coupling, and install gear to frame screws. *(NOTE*—Make certain that scribe marks on coupling and upper steering tube flange are aligned). Install lower flange to coupling nuts. *(NOTE*—After installing gear, check the flexible coupling for distortion. The coupling must rest flat with no visible bend or twist. If it is distorted, remove the lower steering column cover and lower clamp to jacket screw. Loosen steering jacket clamp screws at instrument panel, and slide complete steering jacket assembly up or down as required. Redrill lower clamp and jacket if necessary to install screw). Connect pitman arm to drag link.

REMOVAL: (Upper Steering Shaft)—Remove steering gear assembly (above). Disconnect battery ground strap and remove neutral safety switch and horn contact. Remove horn button and spring and remove steering wheel hub nut. Remove horn retainer and horn ring. Remove steering wheel using Puller J-1859. Remove steering jacket tensioner spring and split ring. Loosen lower steering jacket clamp, pry lower bearing retainer out of steering jacket and remove upper steering shaft through bottom of jacket.

Upper Steering Shaft Lower Bearing Removal & Installation: With upper steering shaft removed, use a soldering iron, and remove upper tip on horn contact wire and remove plastic insulator. Pull the wire down through shaft and out opening at horn contact bushing. Remove bushing with wire from shaft. Slide bearing retainer from shaft and press bearing from retainer. To install, reverse removal procedure.

INSTALLATION: (Upper Steering Shaft)—Slide upper shaft into steering jacket, insert lower bearing retainer into jacket until retainer flange is tight against bottom of shaft, and temporarily tighten lower clamp. Install split ring and steering shaft tensioner spring over end of steering shaft. Install steering wheel over splines on shaft with punch marks lined up. Install horn ring retainer and horn ring in position on steering wheel. Install steering wheel hub nut and tighten to 45-50 ft. lbs. Stake nut to shaft. Install spring and horn button. Loosen lower steering jacket clamp and work lower bearing retainer flange down from end of jacket until 3/16" clearance is obtained between horn ring and directional signal switch carrier. *(NOTE*—To obtain clearance, insert a screwdriver between lower bearing retainer and jacket. Twist screwdriver to move retainer down). Hold lower bearing retainer in position while tightening lower jacket clamp, making certain that lower edge of clamp is as close as possible to lower end of jacket.

STEERING SHAFT UPPER BEARING REMOVAL: Remove neutral safety switch and horn contact from lower steering column. Remove cotter key, dust shield and horseshoe retainer at lower shift lever on steering jacket and then disengage shift lever from shifter tube. Remove steering wheel, tensioner spring and split ring, and direction signal switch (see Upper Steering Shaft Removal above). Remove capscrews holding upper bearing retainer to steering jacket. Remove steering column lower cover. Remove Hydra-Matic shift dial indicator. Pull shifter tube out of steering jacket until shift detent on bearing retainer clears jacket, then screw bearing retainer from shifter tube. Press upper bearing from retainer.

REMOVAL: (Steering Column Assembly)— *(NOTE—Removal of the complete steering column assembly is only necessary when both upper and lower bearings must be replaced or if lower shift lever must be replaced).* Disconnect battery ground strap and remove direction signal switch and horn contact from lower steering jacket. Remove brake pedal retaining screw. Raise car. Disconnect manual control rod from lower shift lever. Scribe marks on coupling and flange to assure correct positioning on assembly, then remove coupling to lower flange nuts. Remove brake pedal. Loosen carpet on left front side and pull back from steering column toe plate and remove plate to floor board screws. Remove stop light switch screws. Remove steering jacket lower cover and remove Hydra-Matic indicator pointer. Disconnect direction signal switch wires at connector. Remove the small screw at bottom of steering jacket-to-instrument panel clamp and remove the two instrument panel to steering column clamp nuts. Remove steering column assembly.

INSTALLATION: Reverse the removal procedure.

STEERING WHEEL & HORN BUTTON OR RING REMOVAL: *See "1954 Cadillac" above.*

1954 CHEVROLET

REMOVAL: Remove steering wheel, then remove upper control shaft clamp bolt from shaft connector and disconnect horn wire at connector under instrument panel near point where wire comes from mast jacket. Remove mast jacket toeboard grommet and seal. Remove instrument panel-to-mast jacket clamp. *CAUTION- Remove any spacers found between brackets and instrument panel as these must be installed when steering gear is installed.* Disconnect gearshift control upper support from mast jacket, then pull upper control shaft and upper

CONTINUED ON NEXT PAGE

SAGINAW (NOT IN LINE) (C ntinu d)

support up and out of engagement with shaft connector. Remove clamp retaining shifter housing to mast jacket, then rotate shifter housing with lower control shaft and control rods away from mast jacket. *CAUTION - Carefully not r lativ position of steering connecting rod parts b for disconnecting them.* Disconnect hoses at valve body unit and cap all openings. Remove nuts, bolts and lockwashers attaching steering gear housing to support bracket. Remove left air duct, then rotate gear assembly to clear fender skirt and raise it up and forward to remove from engine compartment.

INSTALLATION: Reverse removal procedure and note the following: Tighten steering gear housing to bracket nuts to 27-40 ft.lbs. after mast jacket is securely attached.

STEERING WHEEL & HORN BUTTON REMOVAL: Pry out horn button or ornamental cap, then remove steering wheel retaining cap. Remove wheel with Puller J-2927-A. To install, reverse removal procedure and tighten nut to 35-40 ft. lbs. *NOTE - With steering gear on "high spot" (wheels in straight ahead position), steering wheel spok should b horiz ntal.*

1954-55 LINCOLN

REMOVAL: *(NOTE–On cars with power brakes, remove clamp securing reservoir hose to power brake fitting on vacuum cylinder, and remove clamp securing power brake reservoir hose to fire wall. Pull hose to engine side of floor pan opening cover to provide sufficient clearance).* Remove front seat cushion. Remove steering wheel with tool No. 3600-D. Disconnect steering column electrical connections. Remove accelerator pedal from pushrod and remove brake pedal from pedal support bracket. Remove carpeting from floor pan opening. Disconnect speedometer drive cable from instrument panel and remove cover from floor pan opening. Remove support bracket from instrument panel. Disconnect shift rod from steering column shift arm. Loosen clamp on lower steering column at gear housing and raise column sufficiently to disconnect wires at neutral switch. Remove steering column tube from steering shaft through inside of car. Disconnect pressure and return hydraulic hoses at gear valve housing and place hoses in upward position to prevent leakage. Raise front of car and remove pitman arm using tool No. 3590. Disconnect steering gear assembly from frame side rail *(CAUTION–Remove shims, if any, locat d b tw en mounting bolts and frame side rail. Mark bolt hol s and number of shims required, and mark shims for identification with bolt holes).* With one man inside car and another under the car, remove the three bolts securing gear assembly to frame side rail and remove the unit through passenger compartment.

INSTALLATION: Replace steering gear in car and install loosely to frame side rail with the three attaching bolts (longest bolt to rear). Connect hydraulic hoses to valve assembly. Slide steering column tube on steering shaft with column clamp in place (do not tighten clamp). Secure column support to instrument panel bracket with two bolts and tighten finger tight. Tighten bolts securing gear housing to frame side rail *(CAUTION–Replace shims, if any, in the exact position noted at time of removal).* Complete the installation by reversing removal procedure making sure that steering wheel is in center position with wheels straight ahead before pitman arm is installed.

1954-55 OLDSMOBILE

REMOVAL: Disconnect battery, then drain fluid reservoir on pump and disconnect hoses at gear and pump. Cap all hose openings. Loosen mast jacket-to-steering gear housing clamp, then remove steering wheel (see below). Mask steering column for about 2" above instrument panel bracket, then loosen steering column in bracket and remove floor mat and floor pan plate attaching screws. Pull mast jacket upward. Place a 2" block between left front shock absorber arm and frame and jack car up off floor about 10" (place a jack stand under frame). Remove left side filler plate and remove pitman arm from shaft. Remove starting motor and wire bracket and remove steering gear-to-frame bolts. Remove steering gear by pulling it down and out of mast jacket, carefully turning gear as it is removed so that all fittings and pipes clear frame and lower control arms.

INSTALLATION: Reverse removal procedure and tighten gear mounting bolts to 35-40 ft. lbs. *NOTE - Do not tighten gear-to-frame bolts until mast jacket is securely in place. Locate mast jacket to provide 1/4-3/16" clearance between wheel and collar.*

STEERING WHEEL & HORN BUTTON REMOVAL: Disconnect horn wire at relay. On standard wheel, insert sharp instrument under edge of horn button and pry upward. On deluxe wheel, use a small screwdriver to relieve spring tension on one end of spring clips holding horn button in place (accessible from underside of wheel). Remove steering wheel nut, contact plate and horn ring assembly, then pull wheel with a suitable puller.

1954-55 PONTIAC

REMOVAL: *(NOTE–If car is equipped with power brakes, remove power brake unit).* Hook front suspension in 5-passenger load position using tool J-5571 (front suspension hold down hook). Remove steering wheel using puller J-3044. Remove direction signal switch handle and gearshift lever and remove steering column to instrument panel bracket cap. Slide rubber grommet up column jacket. Roll back floor mat and remove pedal plates from floor. Remove neutral safety switch. Disconnect gearshift and selector rods, and direction signal wires. Disconnect oil lines at steering gear and secure lines high enough to prevent oil leakage. Raise car on hoist and remove starting motor, pitman arm, and left side tie rod end. Remove engine side apron on left side. Remove brake pedal hairpin spring retainer and slide pedal to right as far as it will go. If car is on a twin post hoist, it will be necessary to place stands under both front frame ends and lower front post approximately three feet to allow steering assembly to clear hoist. Push steering connecting linkage down and toward rear of car, remove steering assembly to frame attaching bolts, removing the upper bolt last, and lower assembly between lower control arm and steering connecting linkage *(CAUTION–Identify and r tain any shims found betw n gear h using and fram as these must be returned to the sam location for proper alignment of ste ring gear).*

INSTALLATION: Push steering connecting linkage down and toward rear and install steering gear assembly by guiding between lower control arm and connecting linkage. Remove hold down hook. Install front gear housing to frame bolt with lockwasher, finger tight *(CAUTION–Be sure to install shims in the same locations as removed from).* Install steering column lower bracket with lockwashers and bolts to upper bracket on instrument panel. Install two remaining gear housing to frame bolts, and tighten all three bolts. Check for correct shimming of steering gear housing to frame by seeing if steering column aligns with upper bracket when bracket bolts are loosened. If alignment is correct, tighten steering column bracket bolts *(NOTE–If misalignment exists, it will be necessary to change housing to frame shims to correct alignment).* Complete installation by reversing removal procedure.

STEERING WHEEL & HORN BUTTON OR RING REMOVAL: Remove deluxe horn ring button by turning counter-clockwise. Remove standard horn button by pressing down on one side, inserting screwdriver underneath opposite edge of button, and prying upward. Remove locknut, washer, horn ring, horn insulator and contact assembly. Remove steering wheel using puller J-3044. To install, reverse above procedure, making sure wheel is in straight ahead position (spokes horizontal and mark on steering shaft upward). Tighten steering wheel nut to 25-30 ft. lbs. Tighten locknut finger tight plus 1/4 turn.

1954 & LATER STUDEBAKER 1958 PACKARD

REMOVAL: Disconnect and remove battery (on coupe and hardtop, remove battery box). Remove steering post collar screws and slip collar up out of the way. Disconnect horn wire and on automatic transmission cars, disconnect quadrant light and starter cutout switch cables. Disconnect direction signal cables and shift lever rods. Loosen jacket clamp bolt at lower end of jacket. Remove steering wheel using puller J-5473, and remove jacket spring. Loosen jacket to instrument panel bracket clamp screw and remove jacket to instrument panel bracket screws and shims (if shims are used). Slip jacket off column. Remove the four steering post coupling nuts, separate coupling, keeping collector ring and insulators intact, and remove post assembly. Tape coupling studs to prevent damaging threads when removing the unit. On sedan and station wagon models, remove the left hand valve rocker arm cover. Disconnect tie rod from pitman arm and remove the pitman arm clamp bolt. Move fender gravel deflector out of the way and remove the three steering gear housing to mounting bracket bolts. On sedan models it may be necessary to shift the unit against the fender apron for clearance to remove pitman arm, then remove pitman arm. Disconnect hoses at pump and tape all openings. Shift unit rearward, inserting top end of unit through opening in firewall. Lift lower end of unit, turn it as necessary to gain clearance past fender apron and battery box, and lift unit out of car.

INSTALLATION: Reverse removal procedure and note the following: With gear in mid-position (high-spot)

CONTINUED ON NEXT PAGE

SAGINAW (NOT IN LINE) (C ntinu d)

punch mark on end of worm shaft should be at top and "T" stamped on coupling should also be at top, with wheels in the straight ahead position.

STEERING WHEEL & HORN BUTTON OR RING REMOVAL:

Champion & Commander (Custom & Deluxe): Remove horn button assembly by pushing down on button and at same time turning button 1/3 of a turn. Remove wheel retainer and lockplate. Place puller center adapter in end of steering post and remove steering wheel with puller J-5473. To install, reverse removal procedure, tightening nut to 23-27 ft. lbs.

Champion & Commander (Regal), President: Remove button from steering wheel by inserting knife blade under edge of button and forcing button up and out. Remove horn ring retaining screws and remove ring and rubber shock pad. Remove steering wheel retaining nut and lockplate. Place puller center adapter in end of steering post and remove steering wheel with puller J-5473. To install reverse removal procedure, tightening nut to 23-27 ft. lbs.

STEERING GEAR OVERHAUL

OVERHAUL: Steering Gear Disassembly–Thoroughly clean steering gear (mast jacket removed). Place steering gear on holding fixture, then proceed to disassemble as follows:

1) Remove plugs (if hoses removed) from gear housing and attach hoses. Place ends of lines in container and drain gear as much as possible by turning steering wheel two or three times through full range. Remove oil lines between power cylinder and hydraulic control valve housing. Remove small bleed line between power cylinder and hydraulic control valve housing, then the two flexible hoses. (NOTE–Unless "O" ring seals are to be replaced, do not loosen swivel fittings, since they will aid when reassembling oil lines). Remove filler plug with vent.

2) Mark power rack cover and housing, then remove FOUR CORNER BOLTS from guide cover assembly (DO NOT REMOVE THE TWO CENTER BOLTS). Remove cover and guide assembly with all shims.

3) Mark side cover for ease when reassembling, then remove four side cover bolts. Then, tapping on end of pitman shaft with soft hammer, remove pitman shaft, side cover, and gasket as an assembly.

4) On Buick, measure from end of hydraulic valve cover to nearest edge of horn cable contact. On all cars except 1955 Cadillac, remove horn wire and contact from steering column. Turn steering gear to a horizontal position, mark control valve cover, control valve housing and gear housing to facilitate reassembly. Remove steering wheel, place special tool over threads of steering shaft to protect seal in valve cover when removing cover. On 1955 Cadillac, remove coupling flange-to-steering shaft dowel pin, supporting flange from below to prevent shock damage to thrust bearings. Remove flange from splined shaft. Remove felt washer.

5) Remove three valve cover attaching bolts. Carefully slide valve cover from steering shaft. Except on 1955 Cadillac, remove special tool from threads on steering shaft.

6) Mark power cylinder and housing for assembly purposes, then remove four power cylinder-to-housing attaching bolts. Remove power cylinder with gasket.

7) Straighten bent-over tangs on worm bearing adjusting nut lock. Use steering wheel on steering shaft to hold shaft and loosen worm bearing adjusting nut and lock. (NOTE–Deep chamfered side of nut is toward lock). Remove steering wheel, worm bearing adjusting nut and lock.

8) With steering gear still in horizontal position, carefully remove the control valve assembly from steering shaft, using care to keep spool, plungers and centering springs from falling out. *(CAUTION–Do not lay control valve assembly where it is apt to pick up lint of dirt. Lay the control valve assembly on a piece of clean paper).* Remove control valve lower thrust washer assembly from shaft (NOTE–Thrust washer assemblies are interchangeable). Place special tool on threads of steering shaft to protect worm bearing seal in housing, while removing shaft.

9) Remove three end cover attaching bolts and then remove end cover and gasket from housing. Carefully slide steering shaft and ball nut assembly through housing. Holding on to upper end of shaft, to take weight off worm bearing seal, will help to protect seal.

Individual Unit Disassembly & Reassembly–Proceed as follows:

Pitman Shaft & Side Cover–*(NOTE–Lincoln adjusting screw endplay established at time of manufacture. Screw is fixed in end of pitman shaft and cannot be adjusted).* Turn adjusting screw down through side cover and remove side cover from pitman shaft. Remove adjusting screw and shim from slot in pitman shaft (except Lincoln). Clean all parts in suitable solvent. Inspect bushing in side cover for excessive wear. If damaged or worn excessively, replace side cover and bushing. Inspect pitman shaft sector teeth. If pitted, worn excessively or scored, or if pitman shaft serrations twisted, replace shaft. To reassemble (except Lincoln), check fit of pitman shaft adjusting screw shim in slot, in end of pitman shaft. With shim in place, screw head must be free to turn in slot, with no perceptible endplay to .002" loose. If endplay excessive, fit new shim (furnished in four thicknesses). Position adjusting screw, with selected shim, into slot in pitman shaft. (All Cars) Assemble side cover to shaft by turning adjusting screw counterclockwise until side cover seats firmly on housing. Start adjusting screw lock nut over threads of adjusting screw and leave finger tight.

Power Cylinder–Remove gasket and hold power cylinder in vise clamping power rack between brass jaws *(CAUTION–DO NOT place machined surfaces of rack in jaws).* Push power cylinder up to the rack and pull sharply away from rack to hammer adapter against piston (It may be necessary to repeat several times to break grip of rubber seals between adapter and cylinder). Remove safety nut, and piston with one spacer washer from each side of piston. Place Tool J-5293 (Lincoln 33568) over threads of piston rod to protect packing seal in adapter against damage. Remove adapter and large spacer washer from piston rod. (NOTE–Piston, rings, rod, pin and power rack are serviced separately. Adapter "O" Ring Seals are serviced separately or in kit with packing seal). Inspect power rack teeth for burrs, scores or excessive wear. Inspect power cylinder for scores. Inspect "O" ring seals and piston rings. Replace where necessary. Make sure that all parts are clean. Lubricate parts before reassembly. To reassemble, position large spacer washer over rod against power rack. With Tool J-5153 (Lincoln 33568) over threads on rod, install adapter. Install new "O" ring seals on adapter. Remove Tool J-5153 (Lincoln 33568). Install power piston (either side out) having one spacer washer on each side of piston, then install and tighten safety nut. Using ring compressor J-5186 (Lincoln 33569) to compress piston rings, install power cylinder over piston and adapter. It may be necessary to tap cylinder with soft mallet until flush with adapter flange.

Steering Shaft & Ball Nut–Remove clamp and ball return guides from ball nut. Remove sixty (60) steel balls, then carefully remove ball nut from shaft. Wash all parts in clean kerosene or other cleaning solvent. Inspect steering shaft for wear or brinelling in ball and needle bearing races (replace if worn or brinelled). Check shaft to make sure it is straight. Inspect teeth of ball nut and worm of steering shaft. If teeth pitted, worn or scored, replace part. Before reassembling be sure parts are absolutely clean and lubricated with clean engine oil. To reassemble, place steering shaft on bench with upper end to your right. Install ball nut on worm so that when teeth are facing up, deeper side of teeth are toward you. Install 21 or 22 steel balls in each circuit of the worm and ball nut. Install 8 or 9 steel balls in each guide. Holding halves of guide together to prevent the balls from falling out, push guides with balls over each circuit in ball nut. Install clamp and tighten in place. Run ball nut to upper and lower end of worm to check for freeness.

Valve Body–*(CAUTION–Spool and plungers are a very close fit in housing and must be removed and replaced carefully. They must be started carefully to avoid jamming and must not be forced into place).* Carefully remove spool, plungers and springs from valve body. Remove check valve *(CAUTION–Use care not to score or cut bore with screwdriver).* Inspect spool and plungers for scores, nicks, or burred edges. Test check valve by blowing through both ends. Ball should seat when blowing through small end, and allow air to pass when blowing through slotted end. Control valve body and spool are serviced as a unit. Plungers, springs and check valve are serviced separately. Replace damaged parts and make certain they are oiled before reassembly, so that spool and plungers slide freely in housing. To reassemble, install check valve in housing. Assemble spool into housing with counter-bored end up. Install compression springs and plungers.

CONTINUED ON NEXT PAGE

SAGINAW (NOT IN LINE) (Continu d)

Insp cti n & R c nditi ning of Steering Gear Housing & Covers–Clean machined surfaces of housing of all gasket material. Inspect mating surfaces for burrs, and remove any burrs with flat stone. Inspect bushings and bearings for scored or worn condition, and replace if required. The following procedures cover the replacement of all bushings, bearings and seals in housing and covers. To replace, proceed as follows:

Steering G ar H ùsing Worm Bearing & Seal–On Lincoln, place Worm Bearing and Seal Remover Tool-3517 through steering gear end cover opening and drive the seal, washer and bearing from housing. On other cars, remove worm bearing seal by carefully tapping an "offset" screwdriver between seal and shoulder in housing, then pry lightly around seal to remove. Roller bearing is removed with a punch and should not be removed unless replacement is necessary, as removal will damage bearing. To install bearing, use Tool J-5189 (Lincoln Tool 3517-A). Bearing should rest on Shoulder in housing. (NOTE–Stamped end of bearing is against shoulder of installing tool, unstamped end enters housing first). On Lincoln, place washer on bearing so that when seal is installed washer will be between seal and bearing. On all cars, place new seal with lip (spring end) outward toward Bearing Seal installing Tool J-5189 ("Seal" end) (Lincoln 33560) and drive into steering gear housing to point where seal seats on shoulder of housing. *NOTE*–Lubricate feather edges of seal before installing.

Steering Gear S ct r Shaft Bearing, Bushing & Seal–*(NOTE–P wer Steering Gears on Lincoln Cars built aft r January 4, 1954 will not have steering gear s ct r shaft bearing. F r those prior to above proceed as indicated bel w).* To replace bearing on Lincoln cars, turn shaft of Tool 3770-A counter-clockwise until jaws are flush with housing. Insert tool in steering gear housing and turn shaft clockwise until bearing is removed (NOTE–Be sure jaws of tool grip back of bearing). Inspect bearing for binds and freedom of movement. Lubricate bearing with M-4738 lubricant and place on Steering Gear Sector Shaft Bearing Installer Tool 3770, lettered end toward tool, and press carefully into steering gear housing. Recheck bearing for freedom of movement. To remove bushing and seal on Buick, Cadillac, Chevrolet, and Lincoln (On other cars, bushing and housing serviced as an assembly), support steering gear housing in an arbor press and press sector shaft bushing, seal (and retainer, if used) from housing using Tool J-1614 (Lincoln 3353.) Press new bushing into position using bushing driver J-1614 (Lincoln 3353 with adapter 3553-1). Soak new seal in oil, install in new packing retainer (if used) and press into housing (Lincoln use Tool 33587). On Lincoln, seal is installed with lip out. To replace packing or seal only, pry seal (and retainer, if used) out of housing. Soak new seal in engine oil, install in new retainer (if used) and press into housing.

Steering Gear End C ver W rm B aring–Make sure bore in end cover is absolutely clean and that roller bearing is clean. Grip end cover lightly in vise. Insert Removing Tool J-5190 (Lincoln 33551) into bearing and turn screw, which will expand two plates under bearing and will then force tool and bearing out of cover. Use Installing Tool J-5191 (Lincoln 33551-A, Oldsmobile J-5255) to install new bearing. This tool has shoulder to locate bearing at proper depth. Place stamped end of bearing against shoulder of tool so that unstamped end enters bore first. Lubricate bearing with clean automatic transmission fluid.

Hydraulic Valve Cover Seal–Remove seal from valve cover by carefully inserting an "offset" screwdriver between seal and shoulder in cover, and prying lightly around seal. Place a new seal on Tool J-5188 (Lincoln 33562, Oldsmobile J-5254–large end) having spring side (lip side) to shoulder of installing tool. Drive new seal down to shoulder in cover. NOTE–Always lubricate feather edges of seal with clean automatic transmission fluid to facilitate breaking-in the new seal.

Steering Gear Reassembly: Be sure all parts are absolutely clean and lubricated with clean engine oil during reassembly. Proceed as follows:

Lincoln–*(CAUTION–Before installing pitman shaft, tape serrated end of shaft to assure no damage to sector housing end seal.)* Install pitman shaft and cover assembly with new gasket, aligning side cover and steering gear housing marks scribed when disassembled. Secure with two capscrews and two Allen head screws. Loosen adjusting screw locknut. Turn sector shaft upper teeth (nearest side cover) as far as possible toward opening of the steering gear end cover. Turn steering shaft ball nut to top of ball nut race (nearest steering wheel end of shaft). Place Tool 33562-B on steering wheel end of shaft, and slide shaft through steering gear housing cover opening, holding up on shaft to take weight off seal while inserting. Insert first tooth of ball nut into first tooth showing on pitman shaft. Push lightly on ball nut end of steering shaft so as to turn teeth on pitman shaft, meshing them with teeth on ball nut. Install steering gear housing end cover and new gasket with two capscrews and two Allen head screws. (NOTE–If steering gear housing end cover fails to fit snugly against housing, turn shaft slowly to left and right to seat shaft in end cover bearing. DO NOT FORCE.) Install thrust bearing assembly with small race toward gear housing (Thrust bearing assemblies are interchangeable). Place new "O" ring seal in groove in face of housing. Turn holding fixture so that shaft is horizontal. Carefully install control control valve assembly with letter "B" marked on assembly toward housing. Turn steering gear to vertical position, move valve housing around to make sure thrust bearing balls are seated in race, then align marks on valve assembly and steering gear housing. Place Adapter Ring Tool 33577 over valve assembly and secure with three bolts. Center valve spool around worm shaft and tighten bolts evenly and securely. Install upper thrust bearing assembly with large race toward valve spool. Install new worm bearing tab lockwasher making sure inside lock tang slides freely in keyway of shaft, so lockwasher rests flat against upper thrust bearing race. Position locknut over shaft, having deeper chamfer toward tab lockwasher and start nut on threads just far enough so that it is left loose against face of tab lockwasher. Make worm bearing adjustment (see below).

Other Cars - 1) Run ball nut to upper end of worm.

2) On 1955 Cadillac, replace felt washer, reinstall flange on splined shaft, replace coupling flange-to-steering shaft dowel pin.

3) On other cars, place gear housing in horizontal position. Place tool over threads of steering shaft to protect worm seal in housing. Slide shaft through housing, holding up on shaft to take weight off feather edge of seal while shaft is passing through seal.

4) On all cars, install end cover with gasket, tightening in place with bolts and lockwashers.

5) Install lower thrust bearing assembly with large race outward (toward spool). Carefully install control valve assembly (NOTE–Hydraulic connection bosses on control valve housing are identified with embossed letters. The side with identification should be facing up toward steering wheel). Turn steering gear to vertical position, move valve housing around to make sure thrust bearing balls are seated in race, then align chalk marks. Install Adapter Tool J-5182 with valve cover bolts and tighten bolts to 15-20 ft. lbs. torque. Install upper thrust bearing assembly with large race toward valve spool. Install new worm bearing lock nut, and tanged washer (if used) making sure inside lock tang slides freely in keyway of shaft, so lock rests flat against upper race. Position locknut over shaft, having deep chamfer toward lock, and start nut on threads just far enough so it is left loose against face of lock (Nut must spin on threads freely without bind). Make worm bearing adjustment (see below).

Worm Thrust Bearing Adjustment–Temporarily install steering wheel (Studebaker Tool J-5563) after removing special tool from end of steering shaft (or tape from pitman shaft). Turn wheel counter-clockwise to extreme left (Chevrolet right) position so that valve centering plunger springs are fully compressed. Hold wheel in this position and tighten bearing locknut as follows:

►*NOTE:* On 1955 Cadillac, when making this adjustment, use flange and suitable lever to hold shaft stationary.

Buick–Tighten nut just enough to seat thrust bearings against valve spool. Pull at rim required to rotate wheel in off-center range steadily should be 1/2-3/4 lb.

Cadillac–Tighten locknut to 30 ft. lbs. torque, then back off 1/4 turn. Pull at rim required to rotate wheel steadily in off-center range should be 3/8-3/4 lb.

Ch vr l t–Tighten locknut firmly. Back off nut and retighten lightly. Pull at rim required to rotate wheel steadily in off-center range should be 1/4-1/2 lb.

CONTINUED ON NEXT PAGE

SAGINAW (NOT IN LINE) (C ntinu d)

Lincoln—Tighten locknut firmly, then back off nut and retighten lightly. Release wheel (make sure nut exerts pressure against spring-loaded plungers). Adjust to get pull at steering wheel rim of 1/4-5/8 lb.

Oldsmobile—Tighten nut just enough to seat thrust bearings against valve spool, then back off nut 1/16-3/32" measured at one corner of nut hex. Pull at rim required to rotate wheel steadily through off-center range should not exceed 3/8 lb.

Pontiac—Tighten locknut firmly, then back off nut and retighten lightly. Release wheel so that plunger spring pressure is against retaining collar J-5182. Thrust bearing nut should have no lash. Adjust to get pull at steering wheel rim of 1/4-1/2 lb.

Studebaker—Tighten locknut firmly. Turn shaft back to relieve pressure on springs, then, while holding shaft, back off nut until outer race of upper thrust bearing can be turned with a heavy drag.

On all car models, lock the nut by staking nut into shaft keyway (or bend lockwasher tangs against nut flat) using care not to disturb nut position. Remove Adapter Tool. Install new "O" ring seal in cover, use protective thimble on steering shaft to prevent damage to cover seals, install valve cover making certain that aligning marks are lined up, tighten cover screws with torque wrench as follows:

Buick, Pontiac—Securely.
Cadillac—25-29 ft. lbs.
Lincoln—17-22 ft. lbs.
Chevrolet, Oldsmobile, Studebaker - 15 - 20 ft lbs.

NOTE—It is very important that all cover bolts be tightened as closely as possible to exactly the same torque.

Having completed worm thrust bearing adjustment proceed as follows:

Buick—Place adjusting screw and shim in slot of pitman shaft, install side cover with new gasket, and install lock nut finger tight on screw. Place gear assembly on left side, turn steering shaft until ball nut teeth are centered on pitman shaft bushings, and tilt nut slightly toward side cover opening. Hold pitman shaft with gear sectors straight down as it is installed in gear housing; use care to avoid damaging pitman shaft seal in gear housing as shaft is pushed through it. Install side cover and tighten bolts securely. Adjust pitman shaft as follows:

Buick Pitman Shaft High Point Adjustment—Install steering wheel and turn slowly through full range to check for free action, then turn wheel back to center position (2-3/4 turns) to center ball nut on central "high point" of pitman shaft sector. Turn pitman shaft adjusting screw clockwise until lash between ball nut and pitman shaft sector is just removed, tighten lock nut. Turn steering wheel two turns right or left from center. Pull at rim to rotate wheel in range where lash normally exists should be 1/2-3/4 lb. (1952-54), 1/2-7/8 (1955). Place wheel near center position, again check pull required to rotate wheel through "high point". This should be 1/2 - 3/4 lb. gr at r than pull in lash range. Turn adjusting screw as required to obtain this reading after locknut tightened. Record this reading for later use.

Cadillac, Ch vr let, P ntiac, Stud bak r—Place gasket on cylinder and guide power rack through opening in gear housing with teeth on rack pointing toward center of housing. With scribe marks on cylinder and housing aligned, install cylinder-to-housing mounting bolts and tighten securely. Install pitman shaft and engage tapered teeth with ball nut and power rack as follows:

Cadillac—Be sure scribed marks on ball nut and power rack are aligned. Engage teeth of gear with power rack and ball nut.

Chevrolet—Turn steering wheel right or left until center groove of ball nut is in line with center of pitman shaft bushing. Position power rack so that center groove (third groove from piston end) is in line with center of pitman shaft bushing. Install pitman shaft so that center tooth in each set of sector gear teeth meshes with center grooves of ball nut and power rack.

Pontiac—Turn steering wheel clockwise to run ball nut to upper end of its travel. Install pitman shaft in housing with tapered teeth contacting ball nut, engage first tooth of gear with first tooth of power rack and worm gear ball nut.

Studebaker—Same as Chevrolet above.

Lincoln—Proceed with pitman shaft high point adjustment as follows:

Lincoln Pitman Shaft High Point Adjustment—Install steering wheel. Turn steering wheel slowly through full range to check for freedom of movement, then turn wheel back to midway position to center ball nut on central high point of pitman shaft. Turn steering shaft 45° right or left from center. Pull at rim of wheel required to rotate wheel smoothly over center high spot should be 3/4—1 5/8 lbs. Adjust pitman shaft adjusting screw to bring pull within this range. Difference between worm bearing preload (see Worm Bearing Adjustment above) and total preload must not be greater than 1 lb. on 9" radius. Record this reading for use in Power Rack Adjustment below. Tighten adjusting screw locknut to secure adjustment. Recheck adjustment after tightening locknut.

Buick & Lincoln—On Buick, turn steering shaft clockwise to limit of travel. On Lincoln, turn steering wheel until lower pitman shaft teeth are turned completely toward power cylinder opening. On both cars, position power cylinder assembly and new gasket with power rack all the way in cylinder. Align power cylinder and steering gear housing scribe marks. On Buick, mesh end tooth of rack between two end teeth in pitman shaft sector. On Lincoln, mesh first tooth on pitman shaft into first groove on power rack. Torque power cylinder attaching bolts securely (Lincoln 17-22 ft. lbs.)

Oldsmobile—Install steering wheel and turn it right or left until center groove in ball nut is in line with center of pitman shaft bushing. Place pitman shaft with cover and gasket into housing. *CAUTION—T th that engage ball nut ar tapered.* Align center tooth of tapered sector with center groove of ball nut, tap side cover lightly until cover and gasket are flush against housing. Turn steering wheel clockwise all the way. Position power cylinder assembly, with marks aligned, into housing, engaging first tooth on rack into first groove (TOP GROOVE) on sector. Tighten power cylinder attaching bolts evenly and securely.

All Cars—Oil face of power rack and guide, then position power rack cover and guide assembly with all shims onto housing (CAUTION—Use care when holding shims in position to avoid any thin shims catching in bolt threads and face of housing). On Buick and Lincoln, install cover attaching bolts and tighten evenly and securely. On other cars, just start cover bolts with lockwashers through cover. These bolts must be left loose until Over-Center Adjustment has been checked and adjusted. See Over-Center Adjustment below.

Over-Center (Pitman Shaft-to-Ball Nut Lash—Cadillac, Chevrolet, Oldsmobil , Pontiac, Studebak r) Adjustment—With power rack cover bolts loose, turn steering wheel slowly through its full range to check for freedom of movement, then turn wheel back to midway position to center ball nut on central high point of pitman shaft. Turn steering wheel shaft 45° right or left of center. Place spring scale on spoke of wheel at rim and pull on scale, at a 90 angle to spoke, to turn steering wheel. Adjust pitman shaft adjusting screw so that pull on 9" radius to turn wheel smoothly over center high spot is:

Cadillac—1 1/8—1 3/4 lbs.
Chevrolet—1 1/8—1 1/2 lbs.
Oldsmobile—5/8 lb. greater than in lash range (1/2—1 1/4 lbs).
Pontiac—1—1 1/2 lbs.
Studebaker—1/2-1 lb.

Power Rack Guide (Pitman Shaft-t -P w r Rack Lash—All Cars) Adjustm nt—Tighten power rack cover bolts evenly and securely. Turn steering wheel slowly through its full range to check for freedom of movement, then turn wheel back to center position. Turn steering wheel shaft 45° right or left of center. Place spring scale on spoke of wheel at rim and pull on scale, at a 90° angle to spoke, to turn steering wheel. If power rack cover shims have been selected properly there will be a preload in addition to over-center or pitman shaft adjustment when column shaft is rotated past center high spot as follows:

Buick—1/4-1/2 lb. increase or 1 1/4—2 1/4 lbs. total.
Cadillac—1/8-1/4 lb. increase or 1 1/4—2 lbs. total.
Chevrolet—1/8 lb. increase or 1 1/4—1 5/8 lbs. total.
Lincoln—1/32-3/16 lb. increase or 25/32—1 13/16 lbs. total.
Oldsmobile—No increase or 1—1 3/4 lbs. total.
Pontiac—No increase or 1/2-1 lb. total.
Studebaker—1/8 lb. increase or 1 1/4 lbs. maximum.

This completes the overhaul. Reinstall horn wire and contact where necessary. Install steering gear in car (See Removal & Installation above).

HYDRAULIC PUMP: 1954-Early 1956 M dels - *Se "Eaton R t r Typ Pow r St ring Pump" r "Vickers Van Typ (3-Pi c Housing) Pow r St ring Pump".* **Late 1956-58 Models** - *Se "Saginaw Van Type Power St ering Pump".*

SAGINAW "IN LINE" POWER STEERING

Buick (1956-58) ℂ
Cadillac (1956-58)
Contin ntal (1956-58)
Eds l (1958)
Linc ln (1956-58)
Oldsm bile (1956-58)
Pontiac (1956-58)

ℂ - Also used in some early 1959 models

►CHANGES, CAUTIONS, CORRECTIONS

►*1956 END COVER, ADAPTER AND VALVE MOUNTING SEAL PRODUCTION CHANGE* On later cars, the "O" ring seal has been increased in size and its position on the adapter has been changed slightly. Both the early and late type adapters are interchangeable provided the correct "O" ring seal is used.

►*POWER STEERING GEAR SEAL INSTALLATION CAUTION* Particular care must be exercised when installing seals in the 1956 gear housing because fluid under pressure exists throughout housing whenever steering effort is applied Extreme care must be exercised when installing the pitman shaft oil seal

►*1956 BUICK PITMAN SHAFT LASH ADJUSTING SCREW LOCK NUT CHANGE (To eliminate leakage at this point)* A new lock seal nut, Part No. 5684554 having a nylon seal embedded at crimped end of nut, is available for service replacement.

►*1956 CADILLAC POWER STEERING SQUEAK CORRECTION (This squeak is noticed during a turn to left or right)* The squeak is caused by a dry needle bearing in gear assembly end cover. Apply 10W oil to felt washers under worm shaft flange. A small hole is provided in the felt protector on upper worm flange.

►*1956 CADILLAC STEERING GEAR "CLUNKING" NOISE CORRECTION* This noise is heard on hard turns and when steering wheel is turned while car is standing still with engine running. This condition may be corrected by properly positioning the lower steering column seal seat between bearing and seal at lower end of steering shaft. Check to make sure a washer is located under the spring at lower end of steering shaft.

►*1956 CADILLAC POWER STEERING GEAR SIDE COVER & LASH ADJUSTER SCREW CHANGE (Air bleed screw has b en eliminated)* This is a change in partial production and affects cars between Serial No. 139856 to 140136 and 140277 to 140557. Provision has been made for automatic bleed of trapped air in upper area of housing. Bleeding of air from system is accomplished in the same manner as in the past.

►*1956 CADILLAC STEERING KNUCKLE ARM CHANGE* Starting at Engine No. 127270, steering knuckle arms, Part No. 1456119 (right hand), and 1456118 (left hand) are used on all models. When replacing a steering arm, make sure the correct type is installed to match the opposite arm.

►*1956 LINCOLN POWER STEERING HOSE INTERFERENCE WITH UPPER FRONT SUSPENSION CONTROL ARM* If interference is found at this point, rotate the "Banjo" pressure hose fitting to between 8 and 9 o'clock positions as view from left side of car.

►*1956 LINCOLN POWER STEERING CONTROL VALVE PRODUCTION CHANGE* Control valve assembly, Part No. LD-33577-A was used on approximately 9000 early cars. Part No. LD-33577-B is used in later production. Some of the detail parts of the assemblies are not interchangeable. The early type valve is identified by a brush mark of yellow paint across valve housing.

►*1956 STEERING COLUMN RATTLE CORRECTION* Install a new nylon upper steering column bushing, Part No. FDT-3517-A. Before replacing the bushing, Polish all burrs from the shaft.

►*1957 BUICK POWER STEERING PUMP MANIFOLD BREAKAGE NOTE* Excessive leakage at the cover attaching bolt accompanied by a heavy pump growl may be caused by a cracked or broken manifold in bottom of reservoir This condition is caused by overtightening of the cover bolt

►*1957 BALL NUT RETAINING SCREW PRODUCTION CHANGE* A new screw having a hex head socket is now being used in production. Early and late type screws are not interchangeable. *See "Overhaul" below.*

►*1957 CADILLAC PITMAN ARM SHAFT RETAINING NUT TIGHTENING CHANGE* Tightening specifications have been changed from 105-150 ft. lbs. to 100-125 ft. lbs.

►*1957 PONTIAC (EARLY) HIGH POINT MARK ON STEERING SHAFT CAUTION* Some early cars had the "high point" mark on upper end of shaft positioned toward the bottom with wheels in straight ahead position (mark should have been at top). Determine correct "high point" by turning wheel to its mid position by counting the turns from stop-to-stop.

►*1958 BUICK HIGH PRESSURE HOSE PRODUCTION CHANGE* New type hose Part No 5686919 used on later cars New hose does not have center restrictor and eliminates interference with brake line

►*1958 CADILLAC PUMP COVER SCREW TORQUE CAUTION:* Overtightening cover screw beyond 7 9 ft lbs will distort pump cover break seal and cause oil leak or it will distort manifold at bottom of reservoir causing manifold-to reservoir oil leak

►*1958 PONTIAC PUMP RESERVOIR COVER BOLT LEAK CORRECTION·* Remove and discard hose clip (mounted under bolt head) and install copper washer No 568506 in place of clip

DESCRIPTION· Hydraulically operated in-line power steering gear, which combines the recirculating ball type gear with a concentric hydraulic booster Hydraulic fluid is supplied to the steering gear by a constant displacement, belt driven type pump System is designed to give hydraulic assistance when effort required to turn wheels exceeds 2½ lbs at the rim of the steering wheel Maximum effort required to turn wheels, even under most difficult turning conditions, is limited to 5½ lbs at rim of steering wheel Manual steering is available at all times when engine is not running, or when turning effort at steering wheel is less than that required for power assistance

Control Valve Assembly: Located in valve housing directly above steering gear housing Control valve assembly is an open center three way valve containing a control valve mechanically connected by an actuator lever to the thrust bearing assembly on the worm shaft Control valve has two annular grooves which as the valve is moved fore or aft open or close connecting passages between valve body and gear housing In the neutral or straight-ahead position fluid flows from the pump through open center of valve and back to the pump reservoir When steering wheel is turned resistance between roadbed and wheels must be overcome at the point where the power rack cylinder and pitman gear mesh When the steering wheel is turned, this resistance if higher than the preload which is built in the gear will allow the wormshaft to move downward (right turn) or upward (left turn) causing thrust bearing to move downward (right turn) or upward (left turn) causing valve actuating lever to shift the control valve As the valve moves the connecting fluid passage between valve body and lower end (right turn) or upper end (left turn) is opened more fully to fluid from the pump and the connecting passages between valve body and the upper end (right turn) or lower end (left turn) of the cylinder is more fully closed Fluid from pump is then restricted in its flow back to pump reservoir and builds up pressure forcing piston rack upward (right turn) or down (left turn) and providing power assist for the turn Fluid in upper end (right turn) or lower end (left turn) of gear housing is forced back to pump reservoir through return line The greater the resistance between roadbed and wheels, the more the control valve is displaced "Feel of the road" is maintained through a reaction chamber built into the valve body A ball check valve in the valve body allows steering gear to be operated manually when engine is not running or pump is inoperative (fluid circulates within valve body and gear housing Return line to pump reservoir is open to assure a continuous flow of fluid)

Pump & Reservoir Assembly· Hydraulic pump is belt driven from engine crankshaft and supplies oil pressure for hydraulic assist Pump operates continuously when engine is running but a flow control valve recirculates oil within the pump when it is not needed for hydraulic assist A relief valve is provided to limit pump pressure Reservoir is mounted directly above pump and supplies oil as needed

ADJUSTMENT

PUMP BELT ADJUSTMENT: Buick – Tension should be set so that pulley will slip in belt when 40-45 lbs (new belt), 30-35 lbs (old belt) torque is applied to pulley nut

Cadillac (1956) - Loosen pump to mounting bracket screws then move pump outward until belt is tight and tighten screws With shift lever in "N" race engine while turning steering wheel If belt squeals it is too loose and must be retightened

Cadillac (1957-58) - With belt tensioner gauge J 6733 installed adjust belt tension until red line on barrel of gauge is even with the shoulder

Edsel (1958) - With torque wrench and socket on pump pulley bolt torque required to slip pulley against belt friction should be 14 16 ft lbs

Linc ln & Contin ntal (1956-58) - ½" belt deflection midway between pulleys with 5 7 lbs of force applied

CONTINUED ON NEXT PAGE

SAGINAW "IN LINE" (C ntinued)

Oldsmobile (1956) - Loosen pump to bracket attaching bolts Place Tool J-5398 under pump body and over pivot cap screw With a 0-50 ft lb torque wrench adjust drive belt tension to 30 ft lbs This corresponds to a belt deflection of 7/8" with a 25 lb pull applied midway between pump pulley and fan

Oldsmobile (1957-58) - Position Belt Tensioning Gauge No 33-70 on belt Loosen pump attaching clamp screws and move pump away from engine until pointers on gauge index with groove in gauge plunger Tighten Tighten clamp screws

Pontiac (1956-57) - Loosen pump to bracket bolts two full turns so pump falls of own weight Using Tool J-5574 over head of hinge bolt and torque wrench perpendicular to tool, tighten belt to 58-65 ft lbs (new belt) 51-53 ft lbs (old belt)

STEERING GEAR ADJUSTMENTS: Pitman Shaft Endplay Adjustment is the only adjustment that can be made on car. However, Ball Nut Preload and Thrust Bearing Preload should be checked before Pitman Shaft Endplay Adjustment is made. Disconnect pitman arm from pitman shaft or drag link, then proceed as follows

Thrust Bearing Preload Check: Buick - Disconnect pitman arm from intermediate tie rod. Attach Scale J-544-A to spoke of steering wheel at rim. While pulling at a 90° angle to spoke, pull required to turn steering wheel through range where lash normally exists (1/8 turn of wheel from either extreme position) should be ¼-½ lb.

Cadillac - Turn steering wheel two turns off center. Attach spring scale to spoke of wheel at rim. While pulling at 90° angle to spoke, pull required to turn wheel through a 1" arc should be 8-14 ounces.

Lincoln & Continental - Adjustments on car are not recommended, and should be performed when steering gear is removed for overhaul and during reassembly. *See "Overhaul" below.*

Oldsmobile - *(NOTE - Thrust Bearing Preload & Ball Nut Preload are checked in one operation as follows):* Remove pitman arm from shaft, then loosen pitman shaft adjusting screw locknut and thread adjusting screw out to limit of its travel. Attach Spring Scale J-544-A to spoke of wheel (at rim) and check and record pull required to move steering wheel through a 6" arc with steering gear on center position (2¼ turns from either end of steering wheel travel). *NOTE - This pull should be ¼-1¼ lbs.*

Pontiac - *(NOTE - Thrust Bearing Preload & Ball Nut Preload check not required).*

Ball Nut Preload Check: After Thrust Bearing Preload checked (see above), loosen pitman arm shaft adjusting screw locknut and turn adjusting screw a few turns to loosen it. With spring scale attached as for Thrust Bearing Preload Check, check Ball Nut Preload and record the pull.

Buick - Pull through "high point" (on center) should be ¼-¾ lb. higher than for thrust bearing preload.

Cadillac - With steering gear ½ to ¾ turn off center, the pull through an arc not exceeding 1" should be 2-9 ounces in excess of the Thrust Bearing Preload check.

Lincoln & Continental - Checking on car not recommended.

Oldsmobile - *See "Thrust Bearing Pr load Check" abov .*

Pontiac - Checking not required.

Pitman Shaft Endplay Adjustment: Adjust pitman shaft endplay adjusting screw so that pull required to move steering wheel through center (no lash) position is as follows:

Buick - ½-1 lb. higher than for ball nut preload. Total reading should be 1¼-1¾ lbs.

Cadillac - 8-16 ounces higher than for ball nut preload reading, but should not exceed 28 ounces total.

Lincoln & Continental - Adjustment on car not recommended.

Oldsmobile - ½-¾ lb. in excess of thrust bearing & ball nut preload. Total overcenter preload must not exceed 1¾ lbs.

Pontiac - Overcenter preload should be 1¼-1¾ lbs.

LUBRICATION

LUBRICATION: Buick, Cadillac, Oldsmobile, & Pontiac - Every 2000 miles remove cover on reservoir and add Automatic Transmission Fluid, Type "A" as required to bring level up to "Full" mark on side of reservoir. Tighten cover bolt to 7-9 ft. lbs. *CAUTION - Do not overtighten.*

Continental, Edsel, Lincoln - Check fluid level every 2,000 miles and add Auto. Trans. Fluid type "A" to bring level to ½" of top.

BLEEDING

Buick, Oldsmobile, Pontiac (1956): Remove cover fill to full mark on side of reservoir With front wheels off ground engine running and bleed screw in side cover loosened turn steering wheel through its entire range two or three times until there is no evidence of air in system Recheck oil level Tighten bleed screw and replace cover using a new gasket Tighten cover bolt to 8-10 ft lbs

Cadillac (1956): *NOTE - See "Cadillac Power Steering Gear Side Cover & Lash Adjuster Screw Change" above* Remove cover and fill to full mark on side of reservoir Allow fluid to remain undisturbed for about two minutes then crack open air bleed screw on housing side cover. Crank engine (coil wire disconnected) and maintain fluid level in reservoir At the same time, with front wheels off ground turn wheels from side to side Start engine and run at 1500 RPM then turn wheels from right to left a number of times (do not hit stops) Check fluid level and install cover using a new gasket Tighten cover bolt to 10-15 ft lbs

Buick, Cadillac, Oldsmobile, Pontiac (1957-58): Run engine at fast idle for two minutes while turning front wheels from right to left (do not hit stops) Check fluid level

Continental (1956-57): Fill reservoir to full mark, then replace star nut and washer (without cover) Loosen bleed screw in side of cover and start engine With wheels off ground turn steering wheel through its entire travel two or three times Tighten bleed screw, recheck oil level and replace cover

Lincoln (1956-57): Fill reservoir to full mark on dipstick Loosen bleed screw in side cover, then start engine Turn steering wheel through its entire travel several times with wheels off ground Tighten bleed screw recheck oil level and replace dipstick

C ntinental, Edsel, Linc ln (1958): Remove cover then add fluid to proper level Start engine and turn steering wheel through entire travel two or three times to bleed system Recheck fluid level

TESTING

HYDRAULIC PRESSURE TEST: Buick, Cadillac, Oldsmobile, Pontiac – Disconnect pressure line at oil pump, attach Gauge J-5176 to pump, and connect hose to end of gauge where valve is located. With engine at warm idle and gauge valve open, note oil pressure while turning steering wheel from one extreme position to the other. Especially note the maximum pressure which can be built up with the wheel held in either right or left extreme position. *(CAUTION – Do not hold wheel in extreme position for more than 15 seconds because it will drastically increase the oil temperature and cause undue wear on the oil pump).* With oil temperature between 150° F. and 170° F , as measured with a thermometer in the reservoir, the maximum pressure should not be less than 875 PSI (850 PSI on Pontiac) for satisfactory power steering operation. If less than specified, it indicates trouble in the pump, hoses, steering gear, or a combination of these parts.

► *1956 CADILLAC POWER STEERING PUMP PRESSURE REDUCTION (to eliminate a squealing noise) See "Changes, Cautions, Corrections" above.*

Continental & Lincoln – Remove pressure hose from pump and connect Gauge No. 3500 with adapter No. 3500-C between pressure fitting on pump and pressure hose that leads from pump to power unit. Let engine idle and turn wheel for a full right or full left turn. The gauge should read between 800 and 1000 lbs. If pressure is less than 800 lbs., close the valve at gauge and note pump pressure. If it is low with valve closed, it indicates that pump is not operating properly. If pump pressure goes up with valve closed, it indicates that the low pressure in system must be due to internal leakage in power unit, providing all connections are tight.

TROUBLE SHOOTING

TROUBLE SHOOTING: Hard St ering While Driving – Steering adjustment tight, linkage binding.

Hard Steering (Car receives mor assist in on direction than the other): This condition may be caused by either of the following Internal leaks at one or both of the white teflon seals. Correct by replacing seals. If this condition is not corrected by the above, align the valve body as follows. Loosen the three attaching bolts and allow the valve to seek its own location. Tighten the end bolt finger tight, then the two side bolts. Repeat bolt tightening sequence applying a final torque of 15-20 ft. lbs.

Poor Return of Steering Gear to Center: Tires not properly inflated, incorrect caster or toe-in, tight steering linkage, steering gear misalignment, tight sector to rack piston adjustment, sticky or faulty control valve, control valve improperly positioned on steering gear, ball nut and worm preload too tight, worm thrust bearing adjustment too tight, sticky valve actuating lever

Car Leads to On Side or the Other: Due to front end alignment and not to steering gear.

CONTINUED ON NEXT PAGE

SAGINAW "IN LINE" (C ntinu d)

Momentary Increas in Eff rt When Turning Wheel Fast to Right: Air in system

External Oil L aks (Wipe Gear Thoroughly and Make Sure Source of Leakage is Determined): Loose hose connection, damaged hose, housing end cover seal, housing end cover "O" ring seal, adapter "O" ring seal, side cover "O" ring seal, linkage cover "O" ring seals, valve to gear housing "O" ring seals, pitman shaft seal, valve end plug "O' ring seal.

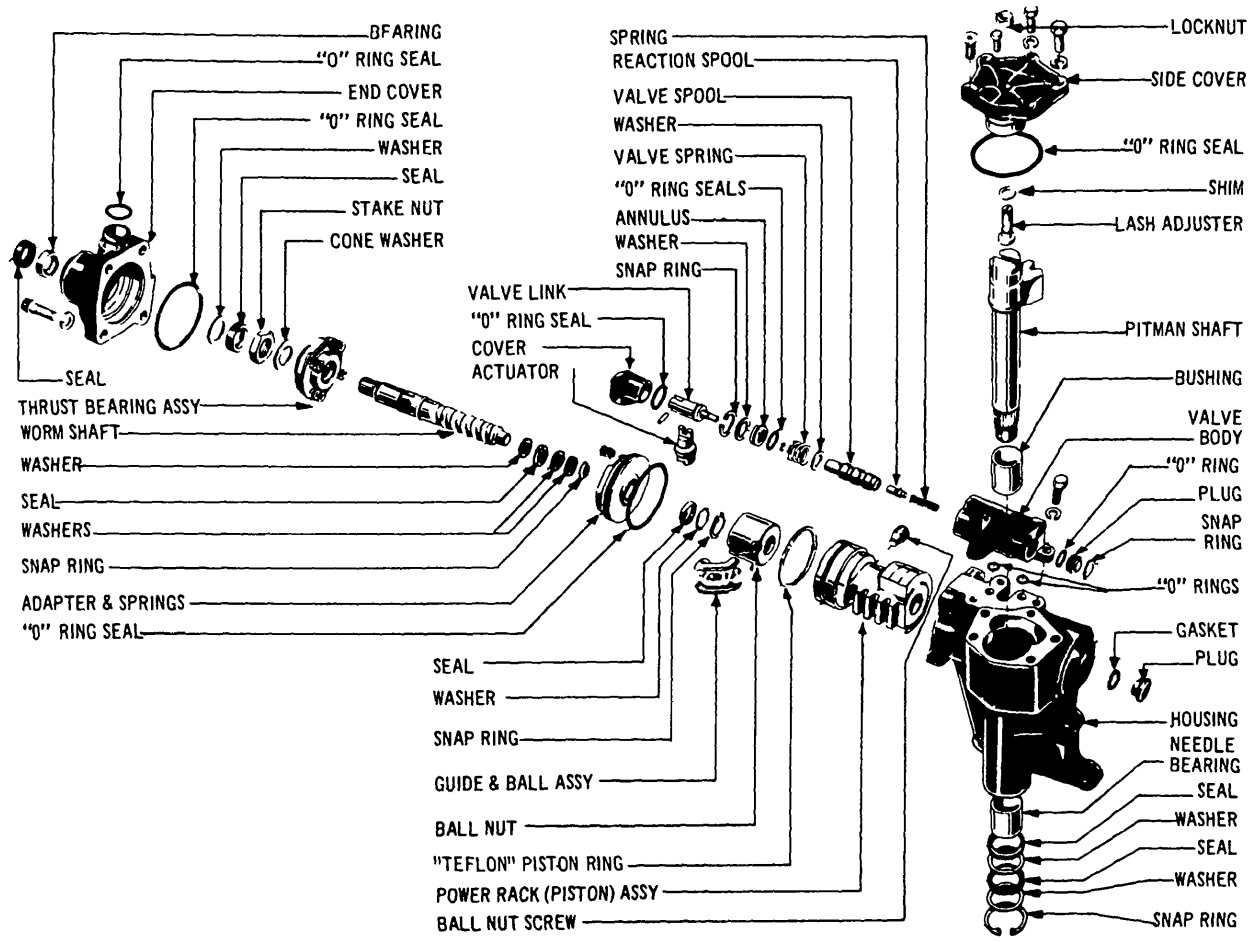
Gear Noise (Rattle or Chuckle): Loose over-center adjustment *NOTE* – A slight rattle may occur on turns because of the increased lash off "high point" This is normal, and the lash must not be reduced below specified limits to eliminate this slight rattle

Gear N is (Hissing Sound): *NOTE* – There is some noise in nearly all power steering systems. One of the most common is a "hissing" sound most evident when at stand-still parking. There is no relationship between this noise and performance of the steering. Hissing may be expected when wheel at end of travel

Exc ssive Wheel Kick-back or Loose Steering: Lash in steering linkage, air in system excessive lash between pitman shaft sector and rack piston, loose worm thrust bearing adjustment

Hard Steering When Turning or Parking: Loose pump belt low oil level in reservoir, lack of lubrication in linkage or front suspension, tires not properly inflated, steering gear adjustments tight, insufficient oil pressure, low oil pressure due to steering gear seal leakage

STEERING WHEEL & HORN BUTTON REMOVAL & INSTALLATION



BUICK

Horn Button Rem val (1956-58 Series 40 Std.) - Pry cap out with thin bladed tool then remove contact cup and other parts by removing attaching screws and insulating spacer bushings To install reverse removal procedure

H rn Button & Ring Rem val (1956-57 Deluxe Steering Wheel) - Pry out monogram which is held by prongs of a retaining spring then remove adjusting nut contact plate and spring with insulators Remove operating ring with cushion and contact spacer *NOTE* - When adjusting nut is being installed turn it down until contact is made and horn blows then back nut off ½ turn to provide proper clearance between contact plate and spacer

H rn Button & Ring Removal (1958 Deluxe Steering Wh el) - Remove three cross-recess screws (from underneath) and remove horn operating ring then remove adjusting nut contact plate and spring (with two insulators) Remove steering wheel nut contact spacer and horn ring adapter To install reverse removal procedure *NOTE* Steering wheel nut does not have lockwasher (self locking type) Turn horn contact adjusting nut down until horn blows and back off ¼ turn at reassembly

St ering Wheel R m val (All Models) - Remove horn button or operating ring (see above), then reinstall steering wheel nut leaving it backed off several turns Set direction signal switch in "Off" position to avoid damage to switch operating mechanism Apply puller J-3274 and pull wheel back to nut *NOTE - If wheel hub very tight on shaft, apply a moderate pressure, th n tap nd of puller screw to break hub loose from shaft without distorting wheel hub* Remove puller nut, and steering wheel

SAGINAW "IN LINE" POWER STEERING GEAR (TYPICAL)

CADILLAC

Horn Ring Removal (1956-58) - Disc nnect horn wire from terminal underneath instrument panel on steering column Loosen Allen head screws on underside of horn ring (one on each side of direction signal carrier) and remove horn ring assembly To install reverse removal procedure

Steering Wheel Removal (1956-58) - Remove horn ring then remove steering wheel nut Remove wheel with Tool J-1859 To install position wheel over splines on shaft so punch marks line up Install hub nut and tighten to 45-50 ft lbs then stake nut to steering wheel Install horn ring

EDSEL

Horn Button & Ring Removal (1958) - Pushbutton Type - Disconnect battery then pry off trim plate medallion with a thin screwdriver Remove screws from plate and remove plate, then pull off pushbuttons Remove screws from inside horn ring hub and lift off ring and trim pad Remove nuts holding contact plate assembly and steering wheel to lower hub Remove contact plate assembly To install reverse removal procedure

Steering Wheel (1958) - Conventional Type - Pry emblem out of wheel hub and remove steering wheel nut Use Tool 3600-AA to pull wheel To install place wheels in straight ahead position and install steering wheel Tighten nut to 60-70 ft lbs

Steering Wheel (1958) - Pushbutton Type - Same as for "Horn Button & Ring Removal" above

LINCOLN & CONTINENTAL

Steering Wheel & Horn Ring Removal (1956-58) - Remove cap and emblem from wheel by inserting a flat instrument between steering wheel hub and horn ring and pushing up Remove steering shaft nut then pull wheel with Tool 3600-A Remove three screws from rear of steering wheel hub and remove horn ring and component parts To install reverse removal procedure

OLDSMOBILE

Horn Button Removal (1956-58) - Standard Wheel - Insert sharp instrument under edge of horn button and pry upward Remove steering wheel nut and contact assembly

Horn Butt n R m val (1956) - D lux Wh l - Two spring clips on ends of horn button engage horn ring

CONTINUED ON NEXT PAGE

SAGINAW "IN LINE" (C ntinu d)

hub and are accessible from underside of wheel To remove horn button, use a small screwdriver to relieve spring tension on one end and lift button from its seat Remove steering wheel nut to remove contact plate and horn ring To install reverse removal procedure

Horn Button Removal (1957) - Deluxe Wheel - Insert a sharp instrument under edge of cap and pry upward Remove steering wheel nut, then remove horn contact assembly To install reverse removal procedure

Horn Button Removal (1958) - Deluxe Wheel - Pry cap from shroud remove horn contact retainer-to-steering wheel hub screw, then carefully pull retainer assembly from hub until contact assembly can be removed To install reverse removal procedure

Steering Wheel Removal (1956-58) - Remove horn button, see above, then use Tool J-1262 to pull wheel from shaft To install, reverse removal procedure and tighten shaft nut to 25 ft lbs (minimum) and stake to steering wheel

PONTIAC

Horn Ring Removal (1956-58) - Standard Wheel - Press down on one side of button and insert a sharp instrument on other side. Pry button out Remove steering wheel nut and contact assembly.

Horn Ring Removal (1956) - Deluxe Wheel - Remove button by turning clockwise Remove locknut, nut, washer, horn ring, horn insulator and contact assembly To install, reverse removal procedure.

Horn Ring Removal (1957) - Deluxe Wheel - Remove screws retaining covers to bottom of horn ring. Remove horn ring side plates, horn ring adapter bushing screws and associated parts To install, reverse removal procedure

Horn Ring Removal (1958) - Deluxe Wheel - Pry up one end and remove ornament, then remove two plate nuts, washers, plate and insulator Lift off horn ring and remove contact (upper), spring and washer Remove lower contact insulator and support, then remove steering wheel locknut, wheel shaft nut and washer To install, reverse removal procedure

Steering Wheel Removal (1956-58) - Remove horn ring or button (see above), then use Tool J-3044 to pull steering wheel To install, reverse removal procedure and tighten nut to 25-30 ft. lbs

REMOVAL & INSTALLATION

Buick (1956): Place a cover over left front fender Disconnect pressure and return line hoses at steering gear and elevate ends of hoses higher than pump to prevent oil from draining out of pump Disconnect flexible coupling by removing two bolts which attach flexible coupling to steering shaft. Jack up car and remove pitman shaft nut, then remove pitman arm Remove four steering gear-to-frame bolts at outside of left frame rail. Remove steering gear. To install, reverse removal procedure Check toe-in

Buick (1957-58): Disconnect pressure and return hoses at steering gear and elevate ends to prevent oil draining from pump. Mark upper and lower steering shaft flanges for correct reassembly, then disconnect the flexible coupling. Raise front of car and remove pitman shaft nut and pitman arm. Remove steering gear to frame bolts and remove steering gear. To install gear, reverse removal procedure. Fill reservoir with oil, then start engine and operate pump, add additional oil until level remains constant. Rotate steering wheel through its entire range slowly a few times, then recheck oil level and replace cover on reservoir.

Cadillac (1956-58): Remove reservoir cover and syphon fluid from reservoir Disconnect pressure and return hoses at reservoir and pump, cap ends to prevent fluid drainage. Raise front of car and place stands near outer ends of lower suspension arms. Disconnect pitman arm from drag link. Remove upper flange-to-upper shaft retaining screw. Remove gear housing-to-frame side side bar screws, remove gear assembly. To install, reverse removal procedure Torque upper flange-to-shaft retaining screw to 25-30 ft lbs. *NOTE*–After installing gear, check flexible coupling for distortion Coupling must rest in flat plane with no visible bend or twist If distorted, remove lower steering column cover and lower clamp-to-jacket screw Then loosen steering jacket clamp screws at instrument panel and slide complete steering jacket assembly up or down as required.

Continental (1956): Working in engine compartment, remove ground cable from battery. Remove screws that retain steering column opening upper and lower cover plates to dash panel. Remove cover plates and insulator. Remove lock pin that retains shift rod to shift arm and remove shift rod from pin on shift arm. Remove spring from pin on shift arm. Working inside passenger compartment, cover front seat and back to protect upholstery. Remove steering wheel (see above). Remove two screws that retain dash panel trim pad to dash panel and remove trim pad: Remove sheet metal screws that secure instrument panel trim and remove trim panel. Disconnect turn signal wires at junction block. Disconnect neutral safety switch and back-up light wires attached to terminal block on steering column. Remove two Phillips head screws that secure upper steering column tube to instrument panel. Slide steering column tube from steering shaft. Raise car, using hoist or suitable jack. Remove nut that secures pitman arm to steering sector shaft. Remove pitman arm from shaft with Tool 3590-AA. Lower car to complete operation in engine compartment. Working in engine compartment, remove air cleaner and air duct as an assembly. Remove two nuts that secure exhaust flange pipe to exhaust manifold. Remove manifold capscrews and remove manifold. Remove number 7 & 8 spark plugs. Remove as much fluid as possible from reservoir with a suction gun. Place oil drain pan under car to catch oil drained from system. Disconnect hoses at power steering gear. Drain steering gear by turning from stop to stop several times. Remove capscrews that secure housing to frame Mark position of any shims found under screws to assure reassembly in same location. *(CAUTION*–Do not attempt to remove rolled pin out of steering shaft coupling at this time). Working in engine compartment, rotate steering shaft so that coupling slot is in a vertical position to facilitate removal of gear assembly. Tilt gear housing down and rearward so that sector shaft is facing up. Lift gear assembly up between fender apron and engine and remove from engine compartment. To install, reverse removal procedure. Secure gear assembly to frame torquing three capscrews to 40-50 ft. lbs., steering wheel to 40-50 ft. lbs , pitman shaft nut to 120-130 ft. lbs. Before attaching pitman arm, count number of steering wheel turns from one extreme to the other and turn wheel back one-half number of turns. With steering wheel and front wheels in straight-ahead position, install pitman arm.

Continental (1957): Disconnect battery cable, then remove steering column-to- dash panel upper and lower cover plates. Remove shift rod at shift arm. Remove steering wheel (see above). Remove dash panel trim pad, then remove trim panel. Disconnect turn signal wires at junction block and neutral switch and back-up wires at terminal block on steering column. Disconnect upper steering column tube from instrument panel and slide tube off shaft. Raise car and remove pitman arm from shaft with Tool 3590-AA. Lower car and remove air cleaner duct and air cleaner as an assembly. Remove exhaust manifold on left side of engine and take out the number 7 and 8 spark plugs. Remove as much fluid from power steering pump reservoir as is possible, using a suction gun. Disconnect hoses at steering gear and drain hoses. Drain steering gear by turning from stop to stop several times. Remove bolts holding gear to frame and note position of any shims found under bolts. *(CAUTION - Do not att mpt to r mov rolled pin out of steering gear shaft coupling at this tim).* Rotate steering shaft so that coupling slot is in a vertical position, then tilt housing down and forward so sector shaft is facing up. Lift steering gear up between fender apron and engine and remove from engine compartment. To install, reverse removal procedure and tighten pitman shaft nut to 120-130 ft. lbs. Bleed hydraulic system after filling reservoir with Automatic Transmission Fluid Type "A". *(See "Bl ding" ab v).*

Lincoln (1956): Working inside passenger compartment remove battery ground cable from battery and cover front seat and back to protect upholstery. Pull speaker lead out of receiver and remove two screws that retain speaker to dash panel. Remove radio speaker Remove steering wheel (see above). Disconnect speedometer cable at speedometer head. Disconnect accelerator rod at clevis pin connection. Remove brake pedal pad. Remove front carpet retaining screws and roll carpet away from steering column opening in dash. Remove clamp from steering column supports. Remove screws that retain supports to floor pan, and remove supports. Remove screws that secure access covers to floor pan and remove access covers. Remove lock pin that retains shift rod to shift arm and remove shift rod from pin on shift arm. Disconnect turn signal wires at junction block. Disconnect neutral safety switch and back-up light wires at terminal block. Remove two Phillips head screws that secure steering column clamp and steering column-to-brake pedal support, and remove steering column from steering shaft. Working through floor pan opening, remove rear manifold cap screw. Raise car using hoist or suitable jack. Remove nut that secures pitman arm to steering sector shaft. Remove pitman arm from shaft with Tool 3590-AA. Remove two nuts that secure muffler inlet to manifold. Remove two forward capscrews that secure steering

CONTINUED ON NEXT PAGE

SAGINAW "IN LINE" (C ntinu d)

gear to frame side rail. Leave remaining capscrew intact so that remaining operations can be performed. Lower car to complete operation in engine compartment. Remove manifold capscrews, remove manifold. Remove numbers 6, 7, and 8 spark plugs. Remove as much fluid as possible from reservoir with suction gun. Place drain pan under car to catch oil drained from system. Disconnect pressure and return line hoses at power steering gear. Drain steering gear by turning from stop to stop several times. Remove remaining bolt that secures steering gear to frame. Place steering gear with coupling slot in a vertical position to facilitate removal. Remove gear by tilting gear housing down and rearward until sector shaft can be removed first. To install, reverse removal procedure. Torque gear-to frame attaching capscrews to 40-50 ft. lbs. Torque steering wheel nut to 60-70 ft. lbs. Torque pitman arm-to-sector shaft nut to 120-130 ft. lbs. When installing steering column tube clearance between upper face of shifter dial and lower edge of horn rim hub should be approximately .18". Tighten steering column upper support-to-brake pedal support screws to 12-15 ft. lbs. Before attaching pitman arm, count number of steering wheel turns from one extreme position to the other and turn wheel back one-half number of turns.

Lincoln (1957): Disconnect cable from battery, then remove radio speaker assembly. Remove steering wheel (see above). Disconnect speedometer cable at speedometer head and accelerator rod at clevis pin connection. Roll carpet away from steering column opening in dash. Remove steering column supports and remove access covers in floor. Disconnect shift rod from shift arm at lower end of steering column. Disconnect turn signal wires at junction block and neutral switch and back-up light wires at terminal block on steering column. Remove steering column clamp and steering column-to-brake pedal support, then remove steering column from steering shaft. Remove rear exhaust manifold screw through hole in floor pan. Raise front of car and remove pitman arm from shaft using Tool 3590-AA. Disconnect exhaust pipe from muffler inlet pipe, then remove exhaust manifold. Remove No. 6, 7, & 8 spark plugs. Using a suction gun, remove as much fluid as possible from power steering reservoir. Disconnect hoses at power steering gear and drain gear by turning from stop to stop several times. Remove bolts securing steering gear to frame. Place steering shaft with coupling slot in a vertical position, then remove gear by tilting gear housing downward and rearward until shaft can be removed first. To install gear, reverse removal procedure and tighten pitman shaft nut to 120-130 ft. lbs. Fill pump reservoir and bleed system *(see "Bleeding" abov).*

Lincoln & Contin ntal (1958): Remove pressure and return hoses from power steering gear. Secure hoses above fluid level, then remove flexible coupling-to-steering gear flange bolts. Raise car and remove pitman arm with Tool 3590-AA. Remove exhaust pipe-to-manifold nuts. Turn front wheels to right turn position and remove steering gear assembly-to-underbody front side member and remove assembly.

Oldsm bil (1956-58): Scribe alignment marks on coupling flange and shaft flange. Disconnect hoses from power steering pump and cap pump and hose fittings. Remove pitman arm from shaft using Tool J-5504-B or similar tool. Remove flexible coupling flange nuts and lock washers, then remove gear assembly-to-frame bolts and remove assembly. To install, reverse removal procedure making sure aligning marks match and gear housing alignment pin enters hole in frame, then tighten bolts to 50-60 ft. lbs. Tighten pitman arm nut to 90-120 ft. lbs.

Pontiac (1956): Remove power brake (if so equipped). Hook front suspension in five passenger load position using Tool J-5571 front suspension hold-down hook. Remove steering wheel (see above). Remove direction signal switch handle and gearshift lever. Remove steering column-to-instrument panel bracket cap. Slide rubber grommet up steering column jacket. Roll back floor mat and remove pedal plates from floor. Remove neutral safety and back-up light switch on Hydra-Matic equipped cars. Disconnect gearshift and selector rods. Disconnect direction signal wires. Disconnect pressure and return line hoses at gear and secure lines so ends are higher than reservoir to prevent leaking. Install plastic plugs or tape to cover gear and line openings. Protect all finished surfaces on steering column with masking tape. Raise car on hoist. Remove starter, pitman arm and left side tie rod end, drop linkage. Remove engine left side apron. Remove brake pedal hair pin spring retainer. Slide pedal to right as far as it will go. If car is on twin post hoist it will be necessary to place stands under both front frame ends and lower front post approximately three feet to allow steering assembly to clear hoist. Push steering connecting linkage down and toward rear of car, remove steering assembly-to-frame attaching bolts, removing upper front bolt last. Lower assembly between lower control arm and steering connecting linkage. *(NOTE -* Check number of shims and avoid loss of shims that are between steering gear housing and frame). Thoroughly clean exterior of steering gear. Steering gear oil can be drained into a container by turning control valve down and turning the worm through steering range several times, To install, reverse removal procedure. Torque pitman arm nut to 100-125 ft. lbs.

Pontiac (1957-58): Scribe alignment marks on steering shaft and worm shaft flanges at coupling above steering gear, then disconnect coupling. Disconnect pressure and return hose assemblies from valve body. Remove pitman arm, then remove gear housing to frame bolts and remove steering gear. To install, reverse removal procedure, making sure that shims found between frame and gear are replaced in their original positions. Tighten pitman arm shaft nut to 100-125 ft. lbs.

OVERHAUL

► *OVERHAUL NOTE: Service procedures are the same for all models except for the following differences:*
1957 & Later - (1) A new needle bearing replaces the former bronze bushing in gear housing at outer end of pitman shaft. (2) A new "Teflon" piston ring replaces the two cast iron rings formerly used on power piston. (3) A new hex head screw is used to retain ball nut assembly, replacing the former screwdriver slotted screw. The rack piston is slotted and hardened at the screw hole. Tighten the new screw to 30-35 ft. lbs. and stake in place, making sure that metal from screw head enters slots in piston. The hex head screw is not interchangeable with earlier type screw.

► *RECIRCULATING BALL INSTALLATION CAUTION:* If both light colored and black balls used, install equal numbers of each color in each of the ball nut guide holes.

► *1957-58 BUICK & PONTIAC PITMAN SHAFT SEAL REPLACEMENT NOTE:* This seal assembly may be replaced with steering gear installed in car as follows: Disconnect pitman arm from pitman shaft, clean end of shaft and tape splines using one layer of tape. Remove pitman shaft seal retaining ring, start engine and turn steering wheel to right until oil pressure forces seals out. When outside diameter of old seals are damaged, inspect housing bore for burrs and correct as necessary. Clean end of housing thoroughly, lubricate seals with petrolatum jelly and install with Tool J-6219 (Single seal first, then back up washer). Drive this seal in to obtain clearance for other seal, back-up washer, and retaining ring. *NOTE - **Inner seal must not bottom on end of counter bore.*** Install double lip seal and back-up washer (drive seal in just far enough to clear retaining ring). Fill reservoir. Check for leaks by running engine and turning wheel right and left. Install pitman arm.

► *1958 CONTINENTAL, EDSEL, LINCOLN SECTOR SHAFT SEAL NOTE:* Both seals can be replaced without removing steering gear from car as follows:
1) Raise car, remove sector shaft nut and remove pitman arm and sector shaft seal snap ring.
2) Clean sector shaft lower grease seal retaining washer and use small thin screwdriver to pry washer from shaft bore.
3) Use two round headed screws No. 10-32 x 1 7/8" (punch holes in seal to start screws) to force seals out.
4) Connect pitman arm (temporarily), place pan under gear, lower car, start engine and make full left turn until sector shaft upper seal and its retaining washer are blown free. Raise car and disconnect pitman shaft.
5) Install seal adapter 3576-J on shaft, position new upper seal over adapter and onto shaft and reinstall washer on shaft.
6) Use Tool 7000-AE to install washer and seal. Install lower seal and retaining washer with Tool 7000-AE. Remove adaptor tool and install snap ring. Tighten pitman arm nut to 120-130 ft. lbs. Check and refill system as necessary with Auto. Trans. Fluid type "A".

STEERING GEAR DISASSEMBLY: 1) Mark alignment of coupling flange and worm shaft. Drive out coupling flange retaining pin *(CAUTION -* Coupling must be supported to prevent damage to bearing in end cover.
2) With the valve body facing down, remove plugs from hydraulic hoses, then turn coupling flange 2 or 3 times through its full travel to drain oil from gear. Remove hoses from valve body. Turn unit so valve body faces upward and remove three valve body capscrews. Remove valve body and linkage cover by pulling straight out from the housing. Remove two valve body to housing "O" rings from housing.
3) Loosen pitman shaft adjusting screw locknut and remove the five side cover capscrews and rotate the cover ½ turn. Align pitman shaft gear with opening in

CONTINUED ON NEXT PAGE

SAGINAW "IN LINE" (C ntinu d)

housing. Tap pitman shaft with a plastic hammer and pull pitman shaft out of housing. Pull coupling flange. 4) Pull actuator from end of housing cover. Remove the four end cover attaching screws and pull end cover from housing. Pull out the worm shaft until centering ring springs are exposed, then remove the four centering springs from adapter. Pull rack-piston and worm assembly out of housing.

CONTROL VALVE: Disassembly – Pull linkage cover from valve body and remove "O" ring. Remove the large snap ring and pull valve assembly and washer from valve body. Remove washer and "O" ring from valve assembly. Remove valve body snap ring; then, using a wooden dowel, push plug from end of valve body. If disassembly of valve assembly is necessary, clamp end of spool valve in Tool J-6293, and using Tool J-6224 remove the valve link. Remove annulus, valve centering spring, and thrust washer from spool valve. Remove reaction control valve and spring from bore in spool valve. Remove inner "O" ring from annulus. If hose connections were leaking at connector seats, remove one or both connectors as follows: Thread a nut and place a washer over a 10-24 tap (for the small connector) or a 5/16" - 18 tap (for a large connector). Coat end of tap with petrolatum to prevent chips from falling into passage while tapping the connector. With valve body in a horizontal position, thread tap into connector not more than three turns. Tighten nut to remove connector by jacking tap and connector out of bore.

Cleaning & Inspection: Wash all parts in clean solvent, blow out all passages, and dry parts with compressed air. Check control valve body for scores, chips or other damage. Control valve must be free to move back and forth in control valve body. Any minor nicks or scratches may be removed with a fine hone.

R assembly: Install new "O" ring seal on valve body plug, coat "O" ring with Hydra-Matic oil, and install plug and snap ring in end of valve body. Clamp end of spool valve in Tool J-6293. Install reaction control spring and reaction control valve (open end out) into valve spool. Install inner and outer "O" rings on the annulus and coat with Hydra-Matic oil. Install thrust washer (bevel side down), valve centering spring, and annulus (narrow land next to spring) on spool valve. Thread link into spool valve and torque to 8-10 ft. lbs. To install new connectors, use Tool J-6217 to seat them in valve body. Carefully insert spool assembly into valve body *(CAUTION* - The spool and valve body are selective fits and have very little clearance. Spool must be properly started into valve body. Do not attempt to force it in). Place steel w a s h e r over link (chamfered side down), then install snap ring (with beveled side out) to retain valve assembly. Install new "O" ring on linkage cover and coat with Hydra-Matic oil. Install linkage cover and align valve link and linkage so that linkage slot is perpendicular with bottom of valve.

PITMAN SHAFT & COVER: Disass mbly – Remove pitman shaft adjusting screw locknut. Thread adjusting screw through pitman shaft cover, then remove cover, adjusting screw and selective shim. Remove "O" ring from cover.

Cl aning & Inspecti n: Wash all parts in clean solvent, blow out all passages, and dry parts with compressed air. Check pitman shaft upper and lower bushings for scoring or damage. Make sure that bearing surfaces of shaft are not nicked or rough. Check sealing surfaces of worm shaft and pitman shaft. Make sure they are free from roughness, nicks or d a m a g e. Minor nicks and scratches may be cleaned up with crocus cloth. Check teeth on pitman shaft and rack-piston for nicks, burrs, or other damage. The pitman shaft adjusting screw has a small nylon plug imbedded in the threaded area which prevents oil from working up threads. This screw with proper shim must be replaced upon reassembly.

Reassembly: Check the endplay of a new adjusting screw in slot of pitman shaft. The screw should rotate freely but not have more than .002" end clearance. Check endplay with a feeler gauge inserted between head of adjusting screw and slot in shaft. If endplay exceeds .002", select the proper shim to give desired endplay. Shims are available in .063", .065", .067", and .069" thicknesses. Thread the adjusting screw through side cover until side cover bottoms on pitman shaft. Install locknut, but do not tighten. Install a new "O" ring into recess in side cover and retain with petrolatum.

END COVER: Disassembly – Remove the two "O" rings. If necessary to replace needle bearing, drive out needle bearing washer and seal. If bearing removal is not necessary, remove seal and washer by driving them out with a screw driver and hammer.

Cleaning & Inspection: Wash all parts in clean solvent, blow out all passages, and dry parts with compressed air. All mating surfaces must be free from nicks and burrs. Remove irregularities with crocus cloth. Inspect actuating lever bore in end cover for wear. If badly worn, the end cover should be replaced.

Reassembly: If needle bearing and seal were removed: Install washer in oil seal recess in cover. Place a new seal over large end of Tool J-5254 with the lip facing shoulder of tool. Install seal so it sits against washer. Coat lip of seal with seal lubricant. Place a new needle bearing over large end of tool J-5254 with the markings against shoulder of tool and drive bearing into end cover until tool bottoms on cover. Make sure needle bearings are free. If seal only was removed, install in same manner as indicated above. Pack needle bearing with a fine fibre grease. Install "O" ring in end cover flange and in "O" ring groove on side of cover. Coat both "O" rings with Hydra-Matic oil.

STEERING GEAR HOUSING: Disassembly – Remove pitman shaft seal by removing snap ring, steel washer, dust seal, and steel washer, then pry out oil seal. If pitman shaft bushing replacement is necessary, drive bushing out with Tool J-6278. If the housing plug shows evidence of leakage, remove the staking with a hack saw, remove any burrs that could score the housing and drive plug into housing to remove it.

Cl aning & Inspection: Wash all parts in solvent, blow out all passages, and dry parts with compressed air. Check housing for scores and undue wear. All mating surfaces must be free from nicks and burrs. Any irregularities may be removed with a crocus cloth. Check housing cylinder for a shoulder condition at either end of ring travel. If shoulder exists due to excessive wear, replace the housing.

Reassembly: If pitman shaft bushing was removed Place Tool J-6278-2 over Tool J-6278, slide new bushing on tool and drive bushing into housing. With Tool J-6278-2 over Tool J-6278, slide seal on tool with lip of seal facing away from tool, and drive seal into housing. Coat lip of seal with seal lubricant. Install steel washer, dust seal, and steel washer, then install snap ring. If housing plug was removed, i n s t a l l a new "O" ring coated with Hydra-Matic oil on a new plug and tap plug into housing. Back up plug with another tool, and stake in 4 places, 90° apart.

RACK-PISTON, WORM SHAFT & BALL NUT ASSEMBLY: Disassembly – 1) Clamp assembly in vise and remove set screw with Tool J-6223. Turn ball nut 180° and pull worm shaft and ball nut assembly from rack-piston. Exercise care so that ball guides do not fall out of ball nut. Tape the end of a three-foot length of string onto the ball nut so that tape also retains ball guides. Tie other end of string to spring scale J-5178, then wrap string around ball nut 3 or 4 times. Slowly pull on spring scale and check over-center pre-load. Pre-load should be 1-6 lbs. *(NOTE* - If over-center pre-load is not within limits, a new set of balls must be installed upon reassembly. Note the size of ball which is stamped on end of the ball nut).

2) Remove the ball return guides. Rotate worm back and forth until all balls have dropped out of nut. Remove ball nut and adapter from worm. Remove adapter "O" ring. Remove Spiralox ring and push washer and seal assembly from the adapter. Cut and remove the worm shaft seal assembly, then remove the snap ring, retaining ring, bronze washer, and steel washer.

3) Tie a three-foot length of string on a thrust bearing centering spring and to spring scale J-544-A. Support the assembly in a vise, wrap string around center race two or three turns, and check pre-load by pulling slowly on string. Pre-load should be ¾-3 lbs. *(NOTE* - The above check will indicate one of three conditions With the pre-load within tolerance and bearing not rough, further disassembly is not necessary. If bearing is not rough but pre-load is outside tolerance, it will be necessary to remove the adjusting nut, install a new one and adjust pre-load to 1½ lbs. If pre-load reading is erratic, indicating a rough bearing, it will be necessary to remove bearing).

4) If bearing replacement is necessary, remove oil rings from rack-piston. Check plug in end of rack-piston. If loose, restake, or replace plug.

Cleaning & Inspection: Wash all parts in solvent, blow out all passages, and dry parts with compressed air. Check bearing assembly for excessive wear or brinnelling of the races. Check sealing surfaces of worm shaft

CONTINUED ON NEXT PAGE

SAGINAW "IN LINE" (C ntinued)

and pitman shaft. Make sure they are not rough and have no nicks or other damage. Clean up minor nicks and burrs with crocus cloth. All mating surfaces must be free of nicks and burrs. Inspect worm and ball nut grooves and all the balls for wear or scoring. If either the worm or ball nut need replacing, both must be replaced as a matched assembly. Make sure that ends of ball return guides are not damaged.

R assembly: 1) If removed, install oil rings on a rack-piston. If thrust bearing was removed, oil a new bearing assembly and install over worm shaft with springs facing away from splined end of shaft.

2) Install washer with tang in keyway and facing splined end of shaft. Install a new nut and adjust pre-load to 1½ lbs., as outlined under "Disassembly" above. Stake nut into keyway of shaft and recheck pre-load. Install new adapter oil seal assembly, then install steel washer and Spiralox ring.

3) Install a new "O" ring on adapter, then slide adapter over worm with holes in adapter facing bearing centering springs. Slide ball nut over worm with beveled side of ball facing the seal end of worm shaft.

4) Install 17 balls into ball nut and lubricate with Hydra-Matic oil *(NOTE - Worm shaft is cam ground (thicker at the center), and the balls can be installed more easily if ball nut is positioned near one end of worm).* Install 6 balls into return guide and retain in place with petrolatum, then install assembly into ball nut. Recheck pre-load as outlined under "Disassembly" above. Place tape over ball guides to retain them in place.

5) If over-center pre-load was not correct (1-6 lbs. pull required to rotate ball nut), as determined at disassembly, install the next larger size balls (if less than specification), or next smaller size balls (if more than specification). Balls are furnished for service replacement in 13 sizes (Exc. Cadillac). On Cadillac, if the pre-load is not correct, a complete worm and ball nut assembly must be installed.

6) Install the steel washer, seal assembly, (neoprene next to steel washer), bronze washer and retainer ring. While holding assembled parts, press worm shaft into snap ring, then force snap ring into groove. Remove tape from ball nut assembly and install worm and ball nut assembly into rack-piston with set screw holes aligned. Clamp rack-piston in a vise and install a new set screw using Tool J-6223. Tighten screw to 20-25 ft. lbs., then stake set screw so that rack-piston metal enters both ends of screw slot.

STEERING GEAR REASSEMBLY: 1) Thread worm out of ball nut as far as possible, position ring gaps opposite each other, and coat oil rings and adapter "O" ring with Hydra-Matic oil. Turn housing so that valve body side is facing up, then place ring compressor Tool J-6216 in recess in housing.

2) With rack-piston teeth facing the pitman shaft area, push rack-piston through ring compressor so that oil rings are just inside housing, then remove ring compressor. With notch in adapter facing machined side of housing, push adapter into housing recess. Install the four centering springs into shallow bores of the adapter.

3) With dowel hole in bearing assembly aligned with adapter dowel, push bearing assembly against the adapter. Place Tool J-6222 over splines of worm shaft, then install end cover and torque capscrews to 25-30 ft. lbs., remove Tool J-6222.

4) Saturate coupling flange wick with Hydra-Matic oil and place over worm shaft. Position coupling flange over worm shaft with alignment marks indexed, but do not install retaining pin. Turn coupling flange so that rack-piston teeth are centered in pitman shaft cover opening in housing. Make sure that rack-piston teeth are square with center-line of pitman shaft bushing.

5) Wrap a piece of masking tape around pitman shaft spline one turn so that tape starts and ends at same wide serration. Install pitman shaft and side cover assembly. The center tooth of pitman shaft must engage the center groove of rack. Install side cover capscrews and tighten the four 3/8" screws to 25-30 ft.lbs. Tighten the 5/16" screw to 15-20 ft. lbs.

6) Install actuator lever in end cover and engage lever with the "flat" on bearing assembly. Install the two "O" rings in housing. With actuator lever engaged with valve link pin, install valve body and torque capscrews to 15-20 ft. lbs. Make sure pitman shaft adjusting screw is backed all the way out.

7) Using Tool J-6281 and spring Scale J-544-A, check and record the combined ball nut and bearing pre-load with gear on center (2¼ turns from either end of travel) and not moving end of Tool J-6281 more than in a 6" arc. Thread pitman shaft adjusting screw in until pitman shaft gear touches rack-piston. While checking combined ball nut and bearing pre-load, adjust pitman shaft screw so that ½ to 1 lb. in excess of ball nut and bearing pre-load recorded above, is obtained. Tighten adjusting nut and recheck over-center pre-load.

8) Install oil hoses and drive in coupling flange pin while supporting worm shaft and flange. Make sure housing alignment pin extends approximately 5/8" from housing.

HYDRAULIC PUMP

Buick, Cadillac, Oldsmobile, Pontiac (1956-58): *See "Saginaw Vane Type" under "Power Steering Pumps".*
Lincoln & Continental (1956): *See "Eaton Rotor Type" under "Power Steering Pumps".*
Lincoln (1957): *See "Eaton Rotor Type" under "Power Steering Pumps".*
Continental (1957): *See "Vickers Vane Type (2-Piece Housing)" under "Power Steering Pumps".*
Edsel, Continental, Lincoln (1958): *See "Eaton Roller Type" under "Power Steering Pumps". NOTE - Used on some Edsel models.*
Edsel (1958): *See "Edsel & Mercury Crankshaft Mounted Type" under "Power Steering Pumps".*

REMOVAL: Buick, Cadillac, Oldsmobile & Pontiac - Disconnect hoses at unions on pump and secure ends in a raised position, or cap the ends to prevent drainage of oil. Install two caps at pump fittings. Remove drive pulley attaching nut and loosen bracket-to-pump mounting bolts. Remove pump belt. Slide pulley from shaft *(NOTE - Do not hammer pulley off the shaft).*

Continental & Lincoln: Remove washer seal, cover, and cover gasket and syphon or pump out as much oil as possible from reservoir. Loosen and move rearward, the clamp securing return hose to reservoir and remove hose from tube. Disconnect pressure hose at fitting on pump assembly and place in a raised position to prevent draining. Loosen pump adjustment capscrew and remove pump belt. Remove two pump adjusting bracket-to-pump support screws. Remove reservoir, pump and pump adjusting bracket as an assembly.

INSTALLATION: Buick, Cadillac, Oldsmobile & Pontiac- Position pump assembly on mounting bracket with holes lined up, and install bolts loosely. Slide pulley on shaft *(NOTE - Do not hammer on pulley).* Install pulley nut finger tight against pulley. Fill reservoir and bleed pump by turning pulley backward (counter-clockwise as viewed from front) until air bubbles cease to appear. Install pump belt over pulley. Move pump outward until belt is properly tensioned (See "Pump Belt Adjustment" above). Tighten pulley nut to 35-45 ft. lbs.

STEERING LINKAGE: *See "Steering Linkage".*

SAGINAW ROTARY VALVE POWER STEERING

Buick (1959-60)Ⓒ
Chevrolet Truck (1960)
Cadillac (1959-60)
Oldsmobile (1959-60)
Pontiac (1959-60)

Ⓒ - Saginaw (In-Line) Power Steering Gear used on some early 1959 models. *See "Saginaw (In-Line) Power Steering".*

►CHANGES & CORRECTIONS

►*1959-60 CADILLAC EXCESSIVELY HIGH POWER STEERING PUMP PRESSURE NOTE: See "Saginaw (Integral Reservoir) Vane Type Hydraulic Pump",*

►*1959 BUICK POWER STEERING PUMP LEAKAGE & NOISE CORRECTION:* A loose expansion plug (located directly under filler cap) may be causing this condition. Oil leaking past the expansion plug under pressure hits the filler cap causing the noise and leakage. To correct, drain oil from pump and hand stake the plug. Refill reservoir to correct level.

►*1959 OLDSMOBILE POWER STEERING HIGH PRESSURE HOSE PRODUCTION CHANGE:* The new high pressure hose, Part No. 5688337 (identified by two yellow tracers on hose) is used in later production cars and should be used for service replacement on all earlier models.

►*1959 PONTIAC POWER STEERING PUMP RESERVOIR FILLER CAP PRODUCTION CHANGE & OIL LEAKAGE CORRECTION:* A new filler cap, Part No. 5687648, identified by locking tabs being in line with ears on cap, is being used in production on all cars without air conditioning. The new cap should be used on previous cars without air conditioning to prevent leakage.

►*1959 PONTIAC ADJUSTER PLUG OIL LEAK CORRECTION:* To correct leakage at adjuster plug, install a new dust seal, Service Kit, No. 5687183, to replace the adjuster plug seal back-up washer. Remove any scores or scratches from stub shaft with crocus cloth before installing seal.

►*1959 PONTIAC POWER STEERING "HISSING" NOISE CORRECTION:* Remove very fine burrs from edge of control valve with crocus cloth. Use crocus cloth very lightly.

►*1959 PONTIAC POWER STEERING NOISE CORRECTION ("Swish" or "Growl" on Low Speed Turns):* If the noise cannot be eliminated by bleeding air from system, proceed as follows: Check positioning of safety drive pins at steering column coupling flange. The pins should be centered in their opening and extend through flange approximately 1/32" to 3/32" (slightly above being flush). If steering column jacket assembly is installed too far down (towards gear), it may be making a metal-to-metal contact and can be corrected by loosening steering column clamp at instrument panel and adjusting column for proper clearance. The clearance between head of lower coupling bolt and flange on steering shaft should be ¼".

►*1959 PONTIAC POWER STEERING PUMP "BUZZING" NOISE CORRECTION:* This noise usually occurs at 800-1000 RPM when engine is accelerated and is caused by clearance in pump shaft. To correct, remove pump rear support and place a thick washer over pump rear mounting studs, then reposition pump and tighten stud nuts to 20-35 ft. lbs. If noise continues, it will be necessary to replace pump shaft assembly.

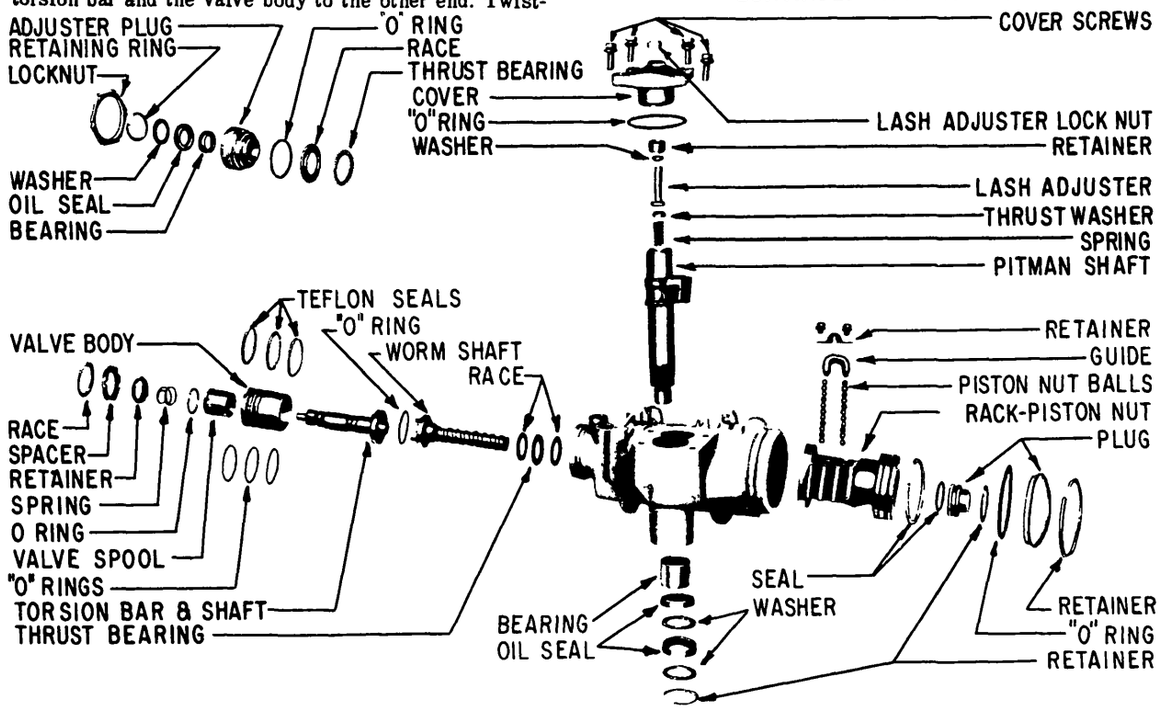
►*1960 POWER STEERING RACK-PISTON PRODUCTION CHANGE:* A new rack-piston having an additional seal ring underneath the Teflon ring is being used in later production and may be used for service replacement. *NOTE - The new "O" ring, Part No. 5687959 and seal, Part No. 5687958 cannot be used on earlier type rack-piston.*

DESCRIPTION: 1959 Models - This hydraulically actuated unit combines a recirculating ball nut and a rack-piston operating in a power cylinder. A rotary type valve actuated by a torsion bar connected to steering shaft controls flow of high pressure fluid from a vane type pump to either end of rack-piston assembly depending on direction torsion bar is rotated. This system is designed to provide power assistance initially with a .3° of steering wheel rotation and one pound of effort at steering wheel rim. Manual steering is available at all times when engine is not running, or when turning effort at steering wheel is less than that required for power assistance. The hydraulic control valve assembly located at upper end of steering gear housing is an open center, rotary type, three-way valve containing a spool that is held in neutral position by a torsion bar. The spool is attached to one end of the torsion bar and the valve body to the other end. Twisting of the torsion bar allows spool to rotate in relation valve body, operating the valve.

1960 Models (Exc. Chevrolet Truck): Design is same as used on 1959 models except as noted below:

Coupling Flange Assembly (Exc. Oldsmobile) - Coupling flange assembly is positioned on stub shaft by a new method that eliminates necessity of scribing marks on these parts during removal.

Adjuster Plug Assembly - Stub shaft seal back-up washer has been replaced by a combination washer and dust seal.



Rack-Piston Nut - A back-up "O" ring seal is used in addition to piston ring in rack-piston nut assembly.

1960 Chevrolet Truck: Control valve assembly of this linkage type power steering unit is located directly on steering gear and is similar to control valve assembly used on cars with "integral" type power steering. Service procedures are different. For steering gear overhaul procedures, *see "Saginaw Ball Bearing Worm & Nut Steering Gear".*

ADJUSTMENTS: Hydraulic Pump Belt (Buick) - Loosen power steering pump mounting bolts and rotate pump assembly to tighten belt until torque required to slip pulley on belt with a torque wrench applied to pulley nut is as follows: **Without Air Suspension** - 30-35 lbs. (Used Belt), 40-45 lbs. (New Belt).

Cadillac - Loosen screws securing pump to mounting brackets, then move pump inward and install Belt

CONTINUED ON NEXT PAGE

SAGINAW (ROTARY VALVE) POWER STEERING GEAR ASSEMBLY

SAGINAW ROTARY VALVE POWER STEERING (C nt.)

Tensioner Tool J-6733 on drive belt Tighten belt until shoulder of gauge is opposite line on barrel of gauge. *CAUTION - Do not use pry bar to move pump.* Tighten pump mounting bolts to 25-30 ft. lbs

Ch vr l t Truck - Loosen power steering pump-to-mounting bracket attaching screws and pull pump outward until a 15 lb load applied midway between pump pulley and fan pulley will deflect belt ½" to ¾" Tighten attaching screws

Oldsm bil - Position Gauge 33-70 on pump belt, then loosen pump attaching bolts and adjust belt tension by moving pump away from engine until pointers on gauge index with groove in gauge plunger. Tighten attaching bolts to 20-28 ft. lbs. and recheck adjustment.

Pontiac - Loosen pump-to-bracket bolts two full turns, then loosen four strap bolts Tighten belt with power steering pump to obtain ¼" belt deflection when a 5-6 lb. load is applied midway between fan and power steering pump pulleys. *NOTE - On cars with Air Suspension, apply load midway between harmonic balancer and air compressor pulley*

Ste ring Gear (On Car): On Buick, Cadillac, & Pontiac, disconnect drag link at pitman arm On Oldsmobile, remove pitman shaft nut, then disconnect pitman arm from shaft using Puller J-5504-B On Oldsmobile & Pontiac, remove horn button, horn ring, or ornament from steering wheel, then install an inch-pound torque wrench on steering shaft nut Proceed as follows

Buick - (Thrust B aring Preload) - Turn steering wheel through its full travel to check for binding,tight spots, or uneven action Turn steering wheel to extreme right or left, then install Scale J-544-A, to a spoke at rim of wheel and pull scale at 90° to spoke Check pull required to turn wheel steadily in range where lash normally exists between rack-piston nut and pitman shaft sector (approximately 1/8 turn from either extreme position) Scale reading should be between ½ and 1¼ lbs *NOTE - Scale reading should be close to minimum specifications on a gear that has been in use On a new gear, the readings will be higher*

Ball Nut Pre-Load Ch ck - Loosen pitman shaft adjuster nut and turn lash adjuster counterclockwise a few turns Check pull required to turn wheel through "high-point" or no lash range This reading should be 1/8 to 5/8 pounds higher than previous reading

Pitman Shaft Endplay Adjustment - Turn pitman shaft clockwise as required to obtain a scale reading ½ to 1 pound higher than that obtained in "Ball Nut Preload Check" *NOTE - This reading taken when pulling wheel through "high point" Total reading should be between 1 1/8 to 2 1/2 lbs*

Cadillac (Thrust B aring Pr load): Turn wheel two turns "off center", then install Distributor Point Checking Scale to a spoke at rim of wheel and pull at 90° to spoke Measure the pull on steering wheel through an arc not exceeding 1" This reading should be between 8 and 14 ozs

Ball Nut Prel ad Ch ck - With scale attached (as above), measure pull on steering wheel through an arc not exceeding 1" wit h the gear ½ to ¾ turn off center The reading should be between 2 and 9 ozs greater than for "Thrust Bearing Preload" above

Pitman Shaft Endplay Adjustment - Adjust lash adjuster screw until pull "through center" on steering wheel is 8 to 16 ozs greater than the pull required for "Ball Nut Preload Check" above *NOTE - Total pull through center should not exceed 28 ozs.*

Oldsmobile (Pitman Shaft Endplay Adjustment): With inch-pound torque wrench installed on steering shaft nut, count number of turns of steering wheel to locate center of travel Check combined ball and thrust bearing preload by rotating wheel through center of travel in an arc not exceeding 20° Note highest reading Tighten adjusting screw until torque wrench reads 4 to 8 lbs higher than first reading This total reading should not exceed 16 inch pounds

Pontiac (Thrust Bearing Preload): Turn steering wheel one full turn off center high point, then attach inch-pound torque wrench to steering shaft nut Effort required to turn wheel should not exceed 10 inch-pounds If reading is below 3 inch-pounds, excessive lash in thrust bearing is indicated

Ball Nut Preload Check - With steering wheel one-half turn off center high point, effort to turn wheel should be ½ to 5 inch-pounds higher than that obtained in preload check above

Pitman Shaft Endplay Adjustment - Effort required to pull wheel through center high point should be 4 to 8 inch-pounds greater than that obtained in "Ball Nut Preload Check" above If reading is not within specifications, loosen pitman arm shaft gear lash adjuster and adjust lash as required Tighten locknut to 25-35 ft lbs *NOTE - Final adjustment should always be made in a clockwise direction (downward)*

LUBRICATION: Check fluid level in power steering pump reservoir every 1000 miles (Buick & Chevrolet Truck), 2000 miles (all others) with steering gear and fluid at normal operating temperature If necessary add recommended fluid (see below) to bring fluid level to mark on reservoir filler neck *NOTE - Use fluid indicated below.*

Buick, Caddil ac & Chevrolet Truck: Use Automatic Transmission Fluid

Oldsmobile (Without Air Suspension): Use Automatic Transmission Fluid

Oldsmobile (With Air Suspension): Use Special Fluid, Oldsmobile Part No 577080

Pontiac (All Models except cars with 2-Cyl. Air Suspension Compressor): Use Automatic Transmission Fluid

Pontiac (Cars with 2-Cyl. Air Suspension Compressor): Use Special Fluid, Pontiac Part No 532186

TROUBLE SHOOTING

HARD STEERING WHILE DRIVING: Frozen steering shaft bearings Lower coupling flange rubbing against adjuster Steering wheel rubbing against gearshift bowl Steering adjustment tight

POOR RETURN OF STEERING: Same as for "Hard Steering While Driving" above, and as follows Tires not properly inflated Front suspension alignment not properly adjusted Tight steering linkage Steering gear misaligned Tightness of suspension ball joints Steering adjustment tight Tight sector-to-rack piston adjustment Thrust bearing adjustment too tight Rack piston nut and worm preload too tight Sticky valve spool

CAR LEADS TO ONE SIDE OR THE OTHER: Front suspension alignment not properly adjusted Unbalanced or badly worn valve *NOTE - If a badly worn valve is the cause, steering effort will be very light in direction of lead and heavy in opposite direction*

MOMENTARY INCREASE IN EFFORT WHEN TURNING WHEEL FAST TO LEFT OR RIGHT: Low oil level in pump Pump belt slipping High internal leakage

GEAR NOISE (RATTLE OR CHUCKLE): Loose over-center adjustment *NOTE - A slight rattle may occur on turns because of increased lash off the "high point" This condit ion is normal and lash must not be adjusted below specified limits*

GEAR NOISE "HISSING" SOUND: Gear loose on frame *NOTE - A "hiss' may be expected when steering wheel is at end of travel or when slowly turning at standstill*

EXCESSIVE WHEEL KICKBACK OR LOOSE STEERING: Air in system Lash in steering linkage Excessive lash between pitman shaft sector and rack piston Loose thrust bearing adjustment. Ball nut and worm preload incorrect

STEERING WHEEL SURGES OR JERKS WHEN TURNING WITH ENGINE RUNNING, ESPECIALLY DURING PARKING: Loose pump belt

HARD STEERING WHEN PARKING: Low oil level in reservoir or loose pump belt Lack of lubrication in linkage or front suspension Tires not properly inflated Insufficient oil pressure Low oil pressure due to restriction in hoses

VALVE SQUAWK WHEN TURNING OR WHEN RECOVERING FROM TURN: Cut or worn dampener ring on valve spool Loose or worn rotary valve parts

NO EFFORT REQUIRED TO TURN: Broken torsion bar

REMOVAL & INSTALLATION
STEERING GEAR

BUICK (1959-60): Removal - Disconnect pressure and return line hoses at gear and elevate end of hose higher than pump to prevent oil draining from pump Disconnect two upper-to-lower flange bolts on coupling, then jack up car and remove pitman arm shaft nut and pitman arm Remove three frame-to-steering gear bolts at outside of left frame rail and remove steering gear

Installation: Reverse removal procedures *NOTE - When installing gear assembly in car, the riveted pins on lower flange and flexible coupling must be installed in center of their correct slots in upper flange (small pin small slot and large pin in large slot) The clip on loose end of horn ground wire must be installed on flange bolt between flexible coupling and upper flang*

CONTINUED ON NEXT PAGE

SAGINAW ROTARY VALVE POWER STEERING (C nt.)

CADILLAC (1959-60): Removal - Syphon fluid from reservoir, then disconnect pressure and return hoses at rear of pump reservoir and secure hoses in a raised position to prevent loss of fluid. Cap pump fitting to prevent drainage of fluid from pump. Raise front of car and place jack stands near outer ends of lower control arms, then disconnect pitman arm from steering gear, using Puller, J-6593. Remove screw holding flexible coupling to upper steering shaft, then remove three screw holding gear housing to frame side rail and remove gear assembly.

Installation: Place steering gear in position on frame side rail, guiding the flexible coupling onto steering shaft, then install three gear housing to frame mounting bolts. Install flexible coupling to upper steering shaft retaining screw and tighten to 25-30 ft. lbs. *NOTE - After installing gear, check flexible coupling for distortion. The coupling must rest in a flat plane with no visible bend or twist.* If it is distorted, loosen screws securing flexible coupling to upper steering shaft and slide upper coupling flange up or down as required. If sufficient adjustment cannot be obtained in this manner, remove lower steering column cover and lower clamp to jack screw. Loosen steering column jacket mounting screws at instrument panel and slide complete steering column jacket assembly up or down as required. *CAUTION - Upper steering shaft and steering gear must be properly aligned.* Connect pitman arm to steering gear, then connect hoses to pump, check fluid level and bleed system.

CHEVROLET TRUCK (1960): Removal - Disconnect steering shaft from lower coupling, then remove hoses from valve. Remove pitman nut, lockwashers and pitman arm. Remove mounting bolts and steering gear.

Installation: Reverse removal procedure.

OLDSMOBILE (1959-60) & PONTIAC (1959): Removal - Scribe alignment marks on coupling flange and steering shaft flange, then remove two coupling flange attaching nuts and lockwashers. Remove horn ground wire from flange attaching bolt. Disconnect hoses from pump and cap pump and hose fittings. Raise car and remove pitman arm with Puller J-5504 or other suitable puller. Remove bolts attaching gear to frame side rail and remove gear with hoses attached,

Installation: Before installing gear assembly, apply a sodium soap fine fibre grease to gear mounting pads to prevent squeaks between gear housing and frame. Reverse removal procedure and note the following: Align coupling flange and steering shaft flange alignment marks so steering wheel will be positioned properly. Make sure alignment pin on gear housing enters hole provided in frame side rail. Before tightening gear to frame bolts, shift steering gear as necessary to place it in same plane as steering shaft so flexible coupling is not distorted. Tighten steering gear to frame bolts to 60-80 ft. lbs., and pitman shaft nut to 120 ft. lbs. Bleed air from hydraulic system.

PONTIAC (1960): Removal - Disconnect pressure and return hoses from gear housing, then disconnect and remove pitman arm from shaft with Puller J-5504. Remove gear housing-to-frame bolts and remove steering gear assembly.

Installation: Reverse removal procedure.

STEERING WHEEL & HORN BUTTON
1959 MODELS

BUICK: Removal - Disconnect wire at horn cable connector on steering column, then remove horn button or operating ring as follows: **Standard Steering Wheel** - Pry cap out with a thin bladed tool, then remove contact cup and other parts by removing attaching screws and insulating spacer bushings. **Deluxe Steering Wheel** - Remove monogram and bezel assembly by prying under bezel. Remove adjusting nut, then remove contact plate and spring with the two insulators. Remove steering wheel nut, contact spacer and cushion, then remove horn ring. With horn parts removed, back off steering wheel nut several turns (if previously removed, reinstall, leaving it backed off several turns). Install Puller J-3274 and pull wheel back to nut. *NOTE - If wheel is tight on shaft, apply a moderate strain with puller, then tap end of puller screw to break hub loose from shaft without distorting wheel hub.* Remove puller, nut, and steering wheel.

Installation: Reverse parts removal sequence.

CADILLAC: Removal - Disconnect horn wire from terminal on neutral safety switch beneath instrument panel on steering column. Remove Phillips screw securing horn ring cap and remove cap. Remove horn ring contact spring and retainer by depressing retainer and turning until retainer and spring snap out. Remove two Allen screws, one on under side of each spoke at steering column and remove spoke ring covers. Remove steering wheel hub and nut, then install Puller J-1859 and remove wheel. Remove horn ring from underside of steering wheel.

Installation: Reverse parts removal sequence.

OLDSMOBILE: Removal - Disconnect horn wire from wiring harness and proceed as follows: **Standard Steering Wheel** - Remove cap-to-steering wheel attaching screw and lockwasher, pull cap from wheel, then disconnect horn switch wire from contact assembly lead. **Deluxe Steering Wheel** - Pry cap and emblem assembly from shroud. With horn parts removed, remove steering wheel attaching nut and washer. Then use a suitable puller to remove steering wheel.

Installation: Reverse parts removal sequence and tighten steering wheel nut to 25 ft. lbs. Stake nut to steering shaft.

PONTIAC: Removal - Standard Steering Wheel - Press down on one side of horn button, then insert a screwdriver under opposite side and pry upward. **Deluxe Steering Wheel** - Pry upward on ornament, then remove plate and insulator. Remove horn ring, upper contact, spring and spring washer. Remove three screws and and insulators from lower contact and support and remove lower contact insulator and support. With horn parts removed, remove steering wheel locking nut and wheel-to-shaft nut and washer. Remove steering wheel with puller, Tool J-3044.

Installation: Reverse parts removal sequence and tighten steering wheel nut to 25-30 ft. lbs.

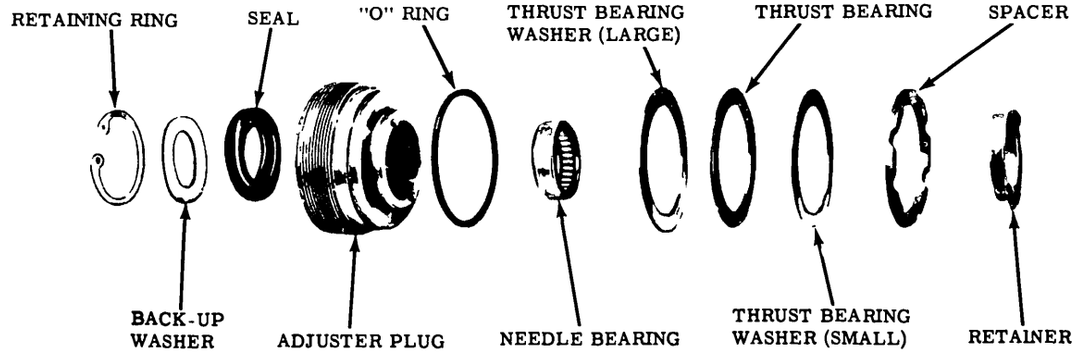
1960 MODELS

BUICK: Removal - Disconnect wire at horn cable connector on steering column, then remove horn button or pushbars as follows: **Standard Steering Wheel** - Pry out cap with a thin bladed tool and pull out contact spring and terminal. Remove steering wheel nut and remove contact cap assembly. **Deluxe Steering Wheel** - Remove emblem assembly from center of steering wheel by prying in recess at lower edge. Remove wing shaped shroud by removing two inner screws from front of and two outer screws from back of wheel. Pull horn wire terminal from center of steering shaft. On all models, loosen steering wheel nut several turns, then install Puller J-3274 and remove wheel.

Installation: Reverse removal procedure.

CADILLAC: Removal & Installation - See *"Cadillac (1959)"* above.

CHEVROLET TRUCK: Removal - Remove horn button and steering shaft nut and washer, then pull wheel with Puller J-2927.



Installation: Reverse removal procedure.

OLDSMOBILE: Removal - Disconnect horn wire from wiring harness and proceed as follows: **Standard Steering Wheel** - Remove cap-to-steering wheel attaching screw and lockwasher and pull cap from wheel, then remove switch wire from contact assembly lead. **Deluxe Steering Wheel** - Pry cap and emblem assembly from shroud. On all models, remove steering wheel attaching nut and washer, then pull steering wheel from shaft with Puller 61-9.

Installation: Reverse removal procedure and tighten nut to 25 ft. lbs. and stake nut to shaft.

PONTIAC: Removal - Standard Steering Wheel - Press down on one side of horn button, then insert a screw-

CONTINUED ON NEXT PAGE

ADJUSTER PLUG ASSEMBLY

SAGINAW ROTARY VALVE POWER STEERING (C nt.)

driver under opposite side and pry out. **Deluxe Steering Wheel** - Twist ornament and lift off, then remove two nuts and washers from shaft. Remove spacer bushing screws and bushing and remove horn ring. Remove pivot ring, spring, insulator and contact plate. Remove contact assembly and insulator. On all models, remove steering wheel with Puller J-3044.

Installation: Reverse removal procedure and tighten steering wheel nut to 25-30 ft. lbs.

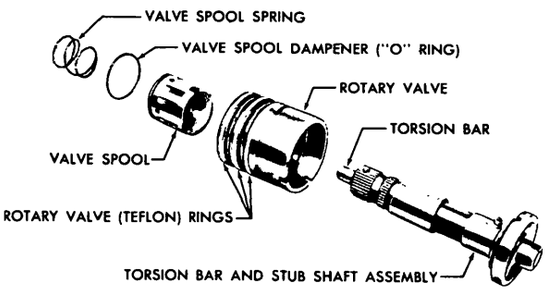
OVERHAUL

►*OVERHAUL NOTE:* Before disassembling unit, clean exterior with a suitable solvent and drain as much hydraulic fluid as possible. Assist draining by placing unit with control valve down and turning the worm through its entire range two or three times. When servicing steering gear assembly, remove only the major gear sub-assembly that requires service.

ADJUSTER PLUG: Removal - On all 1959 models and on 1960 Oldsmobile and Chevrolet Truck, scribe marks on stub shaft and coupling flange to make sure they are assembled in same position. On 1959 models and 1960 Oldsmobile and Chevrolet Truck, remove stub shaft-to-flange retaining screw and remove flange assembly. On other models, remove lower flange pinch bolt and remove flange from shaft. On all models, loosen and remove adjuster plug locknut and remove adjuster plug with Tool J-7624.

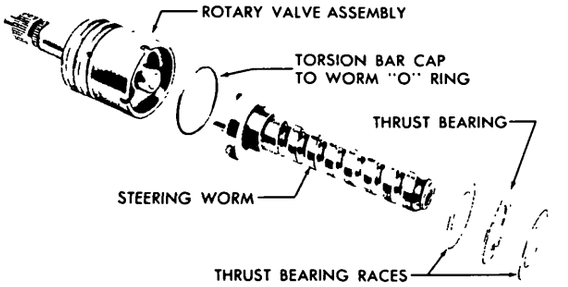
Disassembly - Remove thrust bearing retainer with a screwdriver, being careful not to score needle bearing bore. Discard retainer. Remove thrust bearing spacer, thrust bearing, and thrust bearing races. Remove adjuster plug "O" ring and discard, then remove stub shaft seal retaining snap ring. On Chevrolet Truck, remove seal back-up washer. On other cars, remove and discard dust shield. On all models, remove stub shaft seal by prying out with a screwdriver and discard. Inspect needle bearing in adjuster plug, and if rollers are broken or pitted, remove needle bearing from adjuster plug by pressing from thrust bearing end using Bearing & Seal Remover, Tool J-6221 (Buick & Cadillac), J-5254 (Oldsmobile), J-5188 (Pontiac), J-8524-2 & J-7079-2 (Chevrolet Truck), Discard the bearing.

Inspection - Inspect thrust bearing spacer for cracks, then inspect thrust bearing rollers for wear, pitting, scoring or cracking. If any of these conditions are found, replace both thrust bearing races and check thrust bearing spacer. Inspect thrust bearing races for wear, pitting, scoring, cracking, or brinelling. Replace if necessary. Check thrust bearing and thrust bearing spacer.



►*STUB SHAFT DUST SHIELD INSTALLATION NOTE: Rubber bonded face of shield should be installed toward the retaining ring. On early 1959 models without dust shields having the rubber bonded face, install the later type at reassembly. This shield is part of Seal Kit, Part No. 5687183.*

Reassembly - Install needle bearing by pressing from thrust end of adjuster plug against identification end of bearing using the same tool used for removal. *NOTE - End of bearing must be flush with bottom surface of stub shaft seal bore.* Lubricate stub shaft seal with automatic transmission fluid, then, on Chevrolet Trucks, install seal and back-up washer. On other models, install seal with spring in seal toward adjuster plug. *NOTE - Use Tool J-8524-1 (Chev. Truck); J-5188 (Buick, Cadillac, Pontiac); J-5254 (Oldsmobile) to install seal far enough in plug to provide clearance for retaining ring (Chev. Truck); dust shield (Other Models).* On Chevrolet Truck, install retaining ring. On other models, install dust shield (see note above) with bonded face toward retaining ring, then install retaining ring. Lubricate "O" ring seal with petroleum jelly and install on adjuster plug. Assemble large diameter thrust bearing race, thrust bearing, small thrust bearing race, and thrust bearing spacer on adjusting plug. Press bearing retainer into needle bearing bore with a brass or wooden dowel. *NOTE - Radial position of dimples is not important.*



Installation - Install adjuster plug in end of housing just enough to make certain that all parts are properly seated in gear housing. Back adjuster plug off 1/8 turn and measure valve assembly drag, using a torque wrench. Use a spanner wrench and adjust thrust bearings so that preload of 1-3 in. lbs. (Cadillac, Oldsmobile, Chev. Truck); 3-4 in. lbs. (Buick & Pontiac) in excess of valve assembly drag. Total thrust bearing preload and drag should not exceed 8 in. lbs. (Cadillac, Oldsmobile, Chev. Truck); 10 in. lbs. (Buick & Pontiac). Hold adjuster plug firmly in position and install and tighten locknut. Install coupling shaft assembly on stub shaft (align marks made at disassembly on 1959 models and on 1960 Oldsmobile and Chevrolet Truck). On other models, align groove in lower flange with pin extending from stub shaft and install flange. On all models, center bolt hole in flange with groove on stub shaft. On 1959 models and on 1960 Oldsmobile and Chevrolet Truck, install coupling flange bolt and tighten to 20-25 ft. lbs. On other models, install lower flange pinch bolt and tighten to 20 ft. lbs.

VALVE ASSEMBLY: NOTE - *The complete valve assembly is hydraulically balanced during manufacture. If replacement of any part other than rings or seals is necessary, replace complete rotary valve assembly. DO NOT disassemble valve unless absolutely necessary. If valve spool dampener "O" ring requires replacement, remove valve spool, replace "O" ring and replace spool.*

►*CHEVROLET TRUCK VALVE ASSEMBLY NOTE: Overhaul procedures are the same as for other models with power steering except that free length of valve spool spring is .760-.790",*

ROTARY VALVE ASSEMBLY

TORSION BAR "O" RING LOCATION

Removal: Remove adjuster plug assembly (see above), then remove valve assembly by grasping stub shaft and pulling out.

Disassembly: Remove cap-to-worm "O" ring seal and discard, then remove snap ring from top of spool spring. Remove spring by prying small coil with a small screwdriver. Work spring onto bearing diameter of stub shaft and slide spring off shaft. Remove valve spool. *CAUTION - Clearance between valve body and spool may be as low as .0004" and the slightest cocking of spool may jam it in valve body. To remove valve spool, hold valve assembly in both hands with stub shaft pointing down. Place fingers under valve body and thumbs on valve body cap, holding it against valve body squarely. End of torsion bar should be rapped lightly against bench. This will expose spool far enough so that it may be withdrawn from valve body. Withdraw spool with a steady oscillating pull to prevent jamming. If slight sticking occurs, make a gentle attempt to reverse withdrawal procedure. If this does not free the spool, it has become cocked in valve body bore. Do not attempt to force spool in or out if it becomes cocked. Continue to disassemble valve assembly and return to spool as described later.* Remove stub shaft, torsion bar, and valve cap assembly by holding valve assembly in both hands as before, only with thumbs on valve body. Rap torsion bar lightly against bench. This will dislodge cap from valve body-to-cap pin. The stub shaft, torsion bar, and valve cap assembly can now be removed from valve body. If valve spool has become cocked (see above), it can now be freed. By visual inspection on a flat surface, it can be determined in which direction spool is cocked. A few very light taps with a soft plastic or rawhide mallet should align spool in bore and free it *CAUTION - Do not tap with anything metallic. If spool can be rotated, it can be removed.* Remove "O" ring dampener seal from spool and discard. Carefully cut valve rings and ring back-up seals. Remove and discard.

Inspection: If there is evidence that torsion bar "O" ring seal in stub shaft has been leaking, the entire assembly should be replaced. Check pin valve body that engages the cap. If it is severely worn, cracked, or broken, then entire valve assembly should be replaced. Check smaller of the two worm pin grooves in valve body. If it is severely worn, replace entire valve assembly. Check spool drive pin on stub shaft. If it is severely worn,

CONTINUED ON NEXT PAGE

SAGINAW ROTARY VALVE POWER STEERING (Cont.)

cracked, or broken, replace entire valve assembly. Check spool outer diameter and valve body inner diameter for nicks, burrs, or bad wear spots. If any are found, replace entire valve assembly. *NOTE - A slight polishing is normal on valve surfaces.* Check fit of spool in valve body before installing valve spool dampener "O" ring seal. When lubricated with transmission oil, the spool should rotate smoothly without binding or catching. If either occurs, the entire valve assembly should be replaced. Measure free length of valve spool spring. Free length should be approximately 3/4" to 7/8" (Buick); .82", measured with micrometer (Cadillac); 3/4" (Oldsmobile). *NOTE - If spring measures 11/16" or less (Buick & Oldsmobile), replace the spring.* Examine needle bearing diameter of stub shaft. If it is badly worn, brinelled or scored, replace entire valve assembly.

Reassembly: Lubricate three valve ring back-up "O" ring seals with transmission oil and assemble in three grooves in valve body. Do not allow seals to become twisted. Assemble valve rings in ring grooves over the "O" ring seals by carefully slipping rings over valve body. *NOTE - Rings may appear to be twisted in grooves, but heat of oil after assembly will cause them to straighten.* Install new valve spool dampener "O" ring seal in valve spool groove, then lubricate seals with transmission oil. Do not allow seals to twist in groove. Assemble stub shaft in valve body, aligning groove in valve cap with pin in valve body. Tap lightly on cap with a plastic hammer until cap is seated against shoulder in valve body with valve body pin in cap groove. Hold these parts together during rest of assembly. Lubricate valve spool with transmission oil and slide spool over stub shaft with notch toward valve body. Align notch with spool drive pin in stub shaft and carefully engage spool in valve body bore. *CAUTION - The same care taken in removing the valve spool must be taken when installing it.* Push spool evenly and slowly with a slight oscillating motion until spool reaches drive pin. Rotate spool slowly with pressure until notch engages the pin. Before pushing spool completely in, make sure the dampener "O" ring seal is evenly distributed in spool groove. Slowly push spool completely in, with extreme care taken not to cut or punch the "O" ring seal by inserting the spool beyond normal position. Slide spool spring snap ring over stub shaft and work spool spring and snap ring down with a screwdriver until snap ring is seated in stub shaft groove. Lubricate new cap-to-worm "O" ring seal with transmission oil and install in valve assembly. *CAUTION - If during assembly, the stub shaft cap assembly is allowed to slip out of engagement with valve body pin, the spool will enter too far into valve body, and dampener "O" ring seal will expand into valve body oil grooves, preventing withdrawal of spool. Attempt to withdraw the spool with a slight pull while rotating. If this does not free the spool after several tries, make sure spool is free to rotate. Place valve body on a flat surface with notched end up, and tap spool with wooden or plastic rod until the "O" ring seal is cut and spool can be removed. Replace dampener "O" ring seal and proceed with assembly as before. Make sure that all "O" ring chips are removed bef re assembling the valve.*

Installation: Align valve body drive pin on worm with narrow pin slot on valve body. Insert valve assembly into gear housing. *CAUTION - Do not push against stub shaft, as this might cause stub shaft and cap to pull out of valve body allowing the spool seal to slip into valve body oil grooves.* The valve assembly can be pushed in with one hand by pressing against valve body with finger tips, while pulling out on stub shaft with the palm. Be sure valve is properly seated before assembling adjuster plug assembly. The return hole in gear housing should be fully visible at this time. Install adjuster plug assembly (see above).

PITMAN GEAR SHAFT & SIDE COVER: *NOTE - For removal of pitman shaft seals with steering gear in car, see below.*

Removal & Disassembly: Rotate stub shaft until pitman shaft gear is in center position and remove side cover retaining screws. Tap end of pitman shaft with a soft hammer and slide pitman shaft out of housing. Remove side cover "O" ring seal from side cover and discard. Hold lash adjuster with an Allen wrench and remove lash adjuster nut. Discard adjuster nut. Remove side cover by screwing lash adjuster through cover, using an Allen wrench.

Inspection: Inspect pitman shaft bearing surface in side cover for excessive wear or scoring. If worn or scored, replace cover. Check pitman shaft sector teeth and bearing and seal surfaces. If badly worn, pitted, or scored, replace pitman shaft gear assembly. Check pitman shaft needle bearing in housing for wear. If any of the needle rollers are worn, pitted, or scored, replace the needle bearing. *NOTE - If needle bearing and/or pitman shaft seals in gear housing require replacement, they can be removed at this time (see "Rack Piston Nut & Worm Gear Housing" below).*

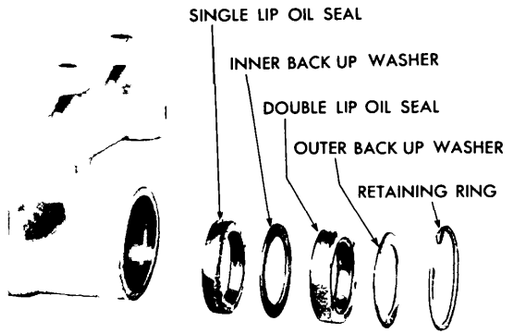
Assembly & Installation: Assemble side cover on pitman shaft gear assembly by screwing lash adjuster through side cover until side cover bottoms on pitman shaft and then backing off ½ turn. Lubricate new side cover "O" ring seal and install in groove in face of side cover. Turn stub shaft as necessary until middle rack groove in rack piston is aligned with center of pitman shaft needle bearing. Install pitman shaft gear so that center tooth in sector meshes with center groove in rack-piston. Make sure that side cover "O" ring seal is in place before pushing side cover down on gear housing. Install side cover screws and tighten to 25-30 ft. lbs. Install new lash adjuster locknut on lash adjuster without tightening. At this point, scribe marks on stub shaft and coupling flange to make certain they are assembled in the same position, then remove stub shaft to coupling flange retaining screw and remove flange assembly. Rotate stub shaft until gear is on center, then loosen adjuster plug locknut. Use a 25 inch lb. torque wrench and measure total preload through center on gear. *NOTE - This should be measured through an arc not exceeding 20° each side of center.* Adjust pitman shaft adjuster screw until total preload measured at stub shaft is 4-8 inch lbs. in excess of total preload recorded above, but not to exceed 16 inch lbs. Tighten adjuster plug locknut, then tighten pitman shaft adjuster screw locknut while holding screw with an Allen wrench. Install coupling flange assembly, making certain that scribe marks are lined up.

RACK PISTON NUT & WORM & GEAR HOUSING: Removal - Rotate end plug retainer ring so that one end of ring is over hole in housing. Spring one end of ring with a punch to allow a screwdriver to be inserted to lift ring out. Rotate stub shaft to left turn position and force end plug out of housing. *CAUTION - Do not rotate further than necessary or balls from rack and worm assembly will fall out.* Remove and discard housing end plug "O" ring seal. Remove rack-piston end plug retaining ring with snap ring pliers. Pull out rack-piston "O" ring seal and discard, then pull out rack-piston end plug. Remove pitmans shaft gear assembly (see above). Insert Ball Nut Bearing Arbor, Tool J-7539, into rack piston against end of worm. Turn worm to force rack-piston nut onto arbor and remove rack-piston from housing. Remove valve assembly (see above), then remove worm and lower thrust bearing and races.

Disassembly: Inspect piston ring. If damaged, remove it from rack-piston nut and discard. Remove return guide clamp screws and remove clamp. Place the assembly on a clean cloth and remove ball return guides, and tool J-7539. Make sure all 22 balls are caught on the cloth. Remove pitman shaft seal retaining ring from gear housing with snap ring pliers, then remove outer back-up washer. Insert a screwdriver between outer seal and inner back-up washer, pry out seal, and remove back-up washer. Insert screwdriver between inner seal and shoulder in gear housing and pry out the seal. *CAUTION - Be careful not to damage seal bore.* Discard seals. Remove needle bearing from gear housing bore by pressing from seal bore side of housing on stamped identification end of bearing with Remover & Installer, J-6657 (Buick & Cadillac), J-6278 (Oldsmobile & Pontiac).

Inspection: Inspect housing bore. If badly worn or scored, replace housing. Inspect high and low pressure line hose connectors in gear housing. If badly brinelled or scored, replace as necessary (see below). Inspect ball plug in valve body end of housing. If it is leaking or raised above the surface, it may be driven in flush to or 1/16" below the surface. The ball can be tightened by staking the housing. Inspect all retaining ring grooves and seal surfaces for defects. Inspect worm and rack-piston nut groove and all of the balls for excessive wear or scoring. If either worm or rack-piston nut need replacing, both must be replaced as a matched set. Inspect ball return guides, making sure that ends where balls enter and leave the guides are not damaged. Inspect lower thrust bearing and races for wear, pitting, scoring, or cracking. If any of these conditions are found, replace thrust bearing and races and check worm. Inspect rack-piston nut teeth for pitting, wear, and scoring. Inspect rack-piston nut outer diameter for wear, scoring, or burrs.

Reassembly: Clean all parts and lubricate them with automatic transmission oil. Install pitman shaft bearing in shaft bore with lettering on bearing facing up, then position bearing with same tool used for removal.



CONTINUED ON NEXT PAGE

SAGINAW ROTARY VALVE POWER STEERING (C nt.)

Upper edge of bearing should be approximately 020" below shoulder in bore Lubricate piston shaft bore and the single lip pitman shaft seal with petroleum jelly and install seal, lip down, into bore with Tool J-6219 (Buick & Cadillac), J-6278 (Oldsmobile & Pontiac) Do not drive seal more than 1/8" below lip of bore Remove tool and place steel washer on top of seal installer tool, and drive seal approximately ½" further into bore Lubricate double lip seal with petroleum jelly and install it into bore, driving it approximately 1/8" into bore with same tool used for inner seal (single lip) Remove tool and place steel washer over seal, then using the same tool, drive both seals down into bore until upper steel washer is just below snap ring groove Install snap ring *CAUTION - To prevent damage to lower seal, drive seals and washers only far enough to install snap ring* Install new piston ring on rack-piston, then insert worm into rack-piston to shoulder Align ball return guide holes with worm groove, then load 16 balls into guide hole nearest the piston ring while slowly rotating the worm counterclockwise to feed balls through the circuit Alternate the black balls with standard balls throughout the circuit Fill one of the ball return guides with the remaining 6 balls Place other guide over the balls and plug each end with heavy grease to prevent balls from falling out when installing guide into rack-piston Insert guides into guide holes of rack-piston (guides should fit loosely), then install return guide clamp over guides Tighten screws to 8-12 ft lbs *NOTE - Check worm preload at this point See "Worm Preload Ch ck" below* Remove valve assembly from worm, then insert Arbor, Tool J-7539, into worm and turn rack-piston onto arbor Do not allow arbor to separate from worm until rack-piston nut is fully in arbor

Worm Prel ad Check: *NOTE - Worm groove is ground with a high point in the center When rack-piston nut passes over this high point, a preload of 1 to 5 inch lbs should be obtained* With nut pointing up, lightly clamp rack-piston nut in a vise having brass jaws *CAUTION - Do not hold rack-piston in area of Teflon ring* Place valve assembly on ring (if not previously installed), engaging worm drive pin Rotate worm until it extends 1¼" from rack-piston nut to thrust bearing face (this is center position) Attach an inch-pound torque wrench with a ⅜" socket to stub shaft Turn wrench through an arc of approximately 60° in both directions several times and take a reading Torque should be 1 to 5 inch lbs If the reading is too high or too low, either replace the rack-piston nut and ball assembly or install next size smaller or larger balls and recheck

Installati n: Assemble thrust bearing and races on worm, then assemble valve to worm by aligning small slot in valve body with pin on worm (be sure to install "O" ring seal between body and worm head) Install valve assembly and worm in housing as an integral unit and install valve (see "Valve Assembly" above) Install Rack-Piston Seal Compressor, J-7576, in gear housing,

PITMAN SHAFT SEAL & WASHER

holding it tightly against shoulder in housing Insert rack-piston nut into housing until arbor engages the worm, then turn stub shaft clockwise, drawing rack-piston into housing When piston ring is into housing piston bore, remove Tool J-7539 and J-7576 Lubricate new "O" ring seal with transmission oil and install on rack-piston end plug (do not allow "O" ring seal to twist in groove) Install rack-piston end plug, tapping it into place with a mallet Install retaining ring with snap ring pliers and make sure it is bottomed in groove Lubricate new housing end plug "O" ring seal with transmission oil and install in gear housing Insert end plug into housing and seat it against "O" ring seal, tapping it into place if necessary Snap end plug retainer ring into place with fingers and bottom it securely in gear housing Install pitman shaft assembly (see above)

STEERING GEAR HOUSING HOSE CONNECTOR SEATS: *NOTE - This operation must be performed with steering gear disassembled to prevent metal chips becoming lodged in valve assembly*

Removal: Tap threads in connectors using a 5/16" - 18 tap, then thread a bolt with a nut and flat washer attached, into tapped hole To pull connector, hold bolt from rotating while turning the nut off the bolt This will pull connector from gear housing Discard connectors *NOTE - A No 4 screw extractor may also be used to remove connectors*

Installation: Clean housing thoroughly to remove all metal chips and dirt, then drive new connectors into place with Tool J-6217 *NOTE - This tool must be modified by grinding 1/16" off end of lower pilot to to prevent damage to poppet valve*

PITMAN SHAFT SEAL REPLACEMENT (STEERING GEAR IN CAR): Removal - Raise front of car and place jack stands near outer ends of lower control arms *NOTE - On Air Suspension cars, raise car to full rebound height by pulling out on "Air Lift" handle on instrument panel* Remove pitman arm retaining nut and lockwasher and remove pitman arm from shaft with a suitable puller Place a container under steering gear to catch fluid, then start engine and turn steering gear to full left turn position (oil pressure will force seals and back-up washers out of housing) Inspect seals for damage If outer diameter appears scored, remove burrs from housing before installing new seals

Installation: Clean end of pitman shaft bore, then wrap a single layer of tape around splines of shaft to prevent damage to seals as they are installed Install seals *(see "Rack-Piston Nut & Worm Gear Housing" above)* Replace pitman arm on pitman shaft and install lockwasher and pitman arm retaining nut Tighten nut to 100-125 ft lbs

HYDRAULIC PUMP: (Exc. Chev. Truck) - *See "Saginaw Vane Type (Integral Reservoir) Power Steering Pump". Chevrolet Truck - See "Chevrolet Power Steering Pump"*

Pump Pressure: As follows

Model	Pressur
Buick	1100-1200 lbs.
Cadillac	1075-1175 lbs.
Chevrolet Truck	① 950-1050 lbs.
Oldsmobile	② 1100 lbs.
Pontiac	③ 900 lbs.

① - At 590 RPM pump speed. ② - Maximum.
③ - Minimum pressure at engine idle speed of 500 RPM.

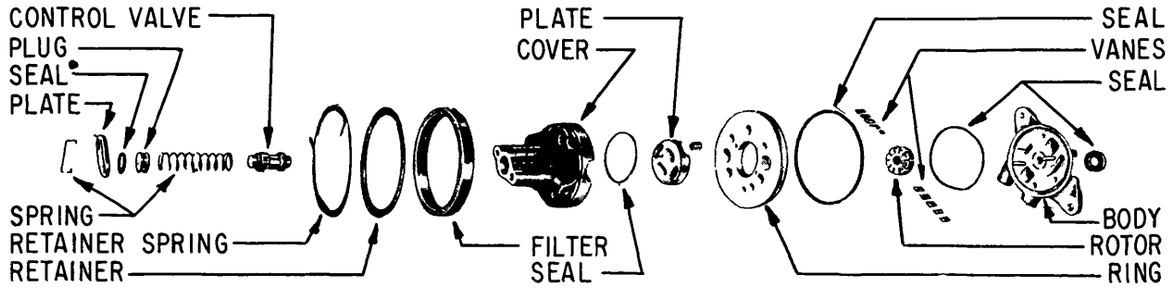
Pressure Test: Disconnect pressure line at pump and install pressure gauge and valve assembly (valve should be between gauge and steering gear), then install pressure line to gauge assembly. With engine at slow idle and gauge valve open, note pressure on gauge while turning steering wheel from one extreme position to the other. Note maximum pressure which is built up with wheel held in either right or left extreme position. *CAUTION - Do not hold at maximum pressur for an extended period of time.* With oil at normal operating temperature (150° to 170°F.), oil pressure should not be less than minimum pressure indicated in table (above). By closing the valve and quickly checking oil pump pressure, it can be determined if low pressure is caused by a faulty pump or leakage in steering gear.

POWER CYLINDER

CHEVROLET TRUCK

POWER CYLINDER: Disassembly - *NOTE - The only repair to make in the field on the power cylinder is to replace piston rod seals.* Before removing piston rod seal parts from rod end of power cylinder, clean the exposed portion of seal cavity with clean solvent, brush and compressed air. Remove snap ring To dislodge scraper, washer, dust seal, seal back-up washer and "U" cup seal, use air hose and apply pressure to cylinder port (right hand port looking down), and seal the left hand port. Remove seal parts from rod

Cleaning & Inspection: Clean all parts in solvent and dry with compressed air. *CAUTION - Do not use waste to wipe off spool or inside bore of valve housing* Protect spool edges and bore of valve housing from damage during disassembly and reassembly Inspect parts for nicks and burrs and excessive wear Check cylinder scraper washer for fit on piston rod, which should be 001-0035". Replace if worn.



Reassembly: Assemble open side of "U" cup seal over the rod and into bearing cavity, seal back-up washer, dust seal (with open side away from seal cavity), and scraper washer Slide parts in place on rod and lock in place with snap ring.

1955-59 CHEVROLET

DESCRIPTION: Vane type pump mounted on commutator end frame of generator and driven by a splined extension of the special generator armature shaft. Pump contains a combination overload relief valve which is set to open at 750 lbs. at 170°F. and a flow control valve which recirculates oil within pump as required to regulate output volume between 1.1 gallons at idling speed and 1.8 gallons per minute at approximately 3600 RPM. Reservoir encloses pump cover assembly and provides a reserve supply of oil.

CHECKING PUMP PRESSURE: Disconnect pressure line at pump connection (smallest, top line), then install checking gauge J-5176 (with gauge valve closed) on pump and hose connection. *NOTE - Adapter Kit J-5900 must be used to connect pressure gauge to pump.* Open gauge valve and run engine at idle speed, then turn wheels (on ground) against stops. Pressure should not be less than 750 lbs. If pressure is less, slowly close gauge valve and check for pressure increase. If pump is in good condition, pressure will increase as valve is closed. *CAUTION - Do not leave valve closed for more than 15 seconds.* If pressure does not increase when valve is closed, pump is faulty. Remove gauge and replace hose.

PUMP OVERHAUL: Removal - On 6 Cyl. cars, loosen generator-to-bracket retaining bolts and remove fan belt. Pull generator all the way out from engine. On all models, place container under pump and disconnect hydraulic lines from pump allowing oil to drain out of reservoir into container. Remove retaining bolts from pump-to-generator and generator rear brace (V8 models), and remove pump. Complete draining remaining oil from pump reservoir before disassembly.

1955-59 CHEVROLET POWER STEERING PUMP ASSEMBLY

Disassembly: Remove retaining bolts and sealing washers from pump reservoir-to-pump cover assembly, and remove reservoir. Remove oil filter spring retainer from pump cover assembly. Remove cover plate spring and cover plate and then remove plug and "O" ring, flow spring and pressure relief valve assembly from pump cover assembly. Remove the three retaining bolts from pump cover assembly and remove pump cover from pump body. Remove oil filter and retainer. Remove cam ring, pump rotor and vanes. Remove and discard "O" rings from pump body, cover and cam ring. Remove and discard generator shaft oil seal from pump body.

Inspection: Wash all parts in solvent and dry with a lint free cloth. Check fit of vanes in rotor. Vanes must slide freely, but snugly in slots. Inspect flat face of pressure plate, cam ring, cover, rotor and pump body. If necessary, lap these parts for a good fit. Check surface of pressure relief valve and check fit of valve in pump cover. Correct slight irregularities by polishing.

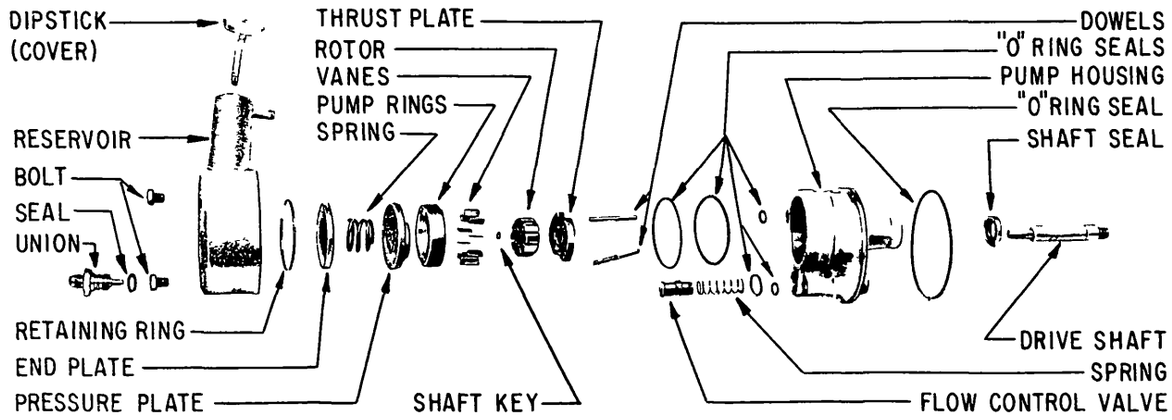
Reassembly: Coat new "O" rings with Lubriplate and install in pump cover, cam ring and pump body. Install rotor and vanes in pump body with wear pattern or beveled edge of vanes against cam ring inner diameter. Install alignment sleeve in cam ring and install cam ring on pump body *(CAUTION–Wid r dg of cam ring should be installed toward pump body. B certain to align bolt holes in cam ring to body b lt hol s. Install rotor with rounded side of splin s toward gen rator end of pump).* Install pressure plate in pump cover and install filter retainer and oil filter. Install cover assembly to pump body, then install plunger and flow spring. Install plug and "O" ring assembly, cover plate, and retainer spring. Install filter retainer spring in cover assembly, and install reservoir, retaining bolts and sealing washers.

►*BRASS FITTING SEAT NOTE:* The seats of the brass fittings are the pressed in type and can be replaced in event of a fitting leak by tapping hole in the seat and then pulling the seat by using a bolt threaded into the tapped out seat and a flat washer and nut as an extractor. When installing new seats, align seat in its bore and press it into place by using the correct hose or tube fitting as a pressure tool.

Installation: Reverse removal procedure.

1960 CHEVROLET

Chevrolet Pass. Cars (1960)
Chevrolet Trucks (1960)



DESCRIPTION: New "Vane" type pump with integral reservoir and pressure regulator valve. The new pump is mounted at front of engine and is belt driven by crankshaft.

LUBRICATION: *See "Chevrolet Pass. Car Power Steering".*

REMOVAL & INSTALLATION: *See "Chevrolet Pass. Car Power Steering".*

DISASSEMBLY: *CAUTION - When clamping pump in vise, be careful not to exert excessive force on front hub of pump as bushing may be distorted.* Remove union and seal, then remove pump rear mounting bolts. On Pass. Cars, remove reservoir from housing by turning counterclockwise until reservoir can be lifted freely from housing. On trucks, rock housing back and forth to remove. Remove endplate retaining ring (depress ring using 1/8" diameter hole in pump housing, then pry out). Remove spring loaded end plate (rock slightly if stuck), then remove pressure plate spring (Pass. Cars); two springs (Trucks). Remove pump from vise and invert it, allowing flow control valve and spring to drop out. Remove end plate "O" ring, then with pump housing turned over, tap housing on a wooden block until pressure plate drops out. Remove pressure plate, pump rings and vanes, being careful not to drop these parts.

CONTINUED ON NEXT PAGE

1960 CHEVROLET POWER STEERING PUMP ASSEMBLY

1960 CHEVROLET (C ntinued)

Install housing in a vise and use a suitable tool to remove snap ring on end of drive shaft. Remove rotor and thrust plates, then remove shaft through front of housing.

REASSEMBLY: Clean all parts in clean solvent, except "O" ring seals and drive shaft seal. *NOTE - Install new "O" ring seals at all necessary points.* Insert shaft at hub end of housing (spline end entering mounting face side). Install thrust plate on dowel pins with ported face at rear of pump housing, then install rotor, which must be free on splines, on pump shaft over splined end. *NOTE - Assemble rotor with count rsunk side toward shaft.* Use a suitable tool and install shaft retaining ring. Install pump ring on dowel pins with direction of rotation arrow to rear of pump housing (rotation is clockwise). Install vanes in rotor slots with radius edge towards outside, then lubricate outside diameter and chamfer of pressure plate with vaseline and install on dowel pins with ported face toward pump ring. Use a 2¾" diameter tube to apply pressure to outer edge only and seat pressure plate by pressure on sleeve (use an arbor press). *CAUTION - Do not press or hammer on center of pressure plate as this will cause permanent distortion.* On passenger cars, install pressure plate spring in center groove of pressure plate. On trucks, install a pressure plate spring over each of the two dowels. On all models, install end plate "O" ring, then lubricate outside diameter and chamfer of end plate with vaseline and install in housing, using an arbor press. While pump is in arbor press, install end plate retaining ring, making sure it is properly seated in groove of housing. Install flow control spring and flow control plunger. *NOTE - End of plunger with hex head screws goes into bore first.* Position reservoir so filler tube is 30° counterclockwise of normal position, then drop into place and rotate clockwise to normal position, pressing down until reservoir seats on housing. Install studs, stud seals, union, union seal, and drive shaft key. Support shaft on opposite side of key when installing key.

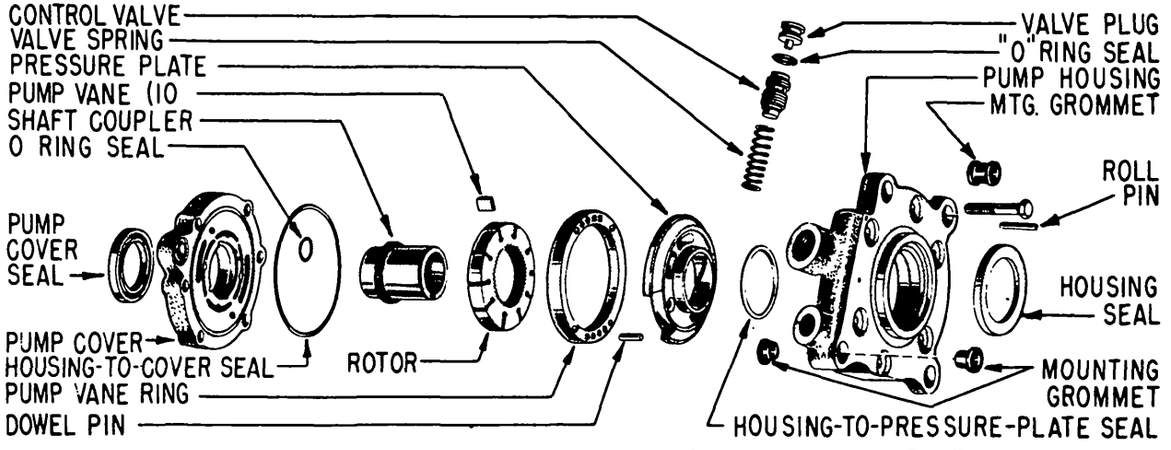
PRESSURE TEST: See *"Chevrolet Pass. Car Power Steering".*

EDSEL, LINCOLN & MERCURY (CRANKSHAFT MOUNTED) TYPE

►CHANGES, CAUTIONS, CORRECTIONS

►*PUMP INLET TUBE ALIGNMENT CAUTION:* Misalignment of pump inlet tube with reservoir outlet tube can cause kinking or interference with water pump resulting in damage to hoses or pump.

DESCRIPTION: Constant displacement "vane" type rotary pump with a built in pressure control valve assembly. Pump is mounted on front of engine and is driven directly by engine crankshaft. Fluid reservoir is not integral with pump and is mounted on forward end of left hand cylinder block.



REMOVAL: Remove radiator, then loosen generator adjusting strap, and remove belts, fan, spacer, and pulley. Drain power steering system and disconnect hydraulic fittings. Remove crankshaft damper with Tool 6306-AG, then remove crankshaft key. Remove four attaching bolts and slide pump off crankshaft. *NOTE - If pump does n t slid off crankshaft easily, use Tool 6306-AG.*

DISASSEMBLY: Clean exterior of Pump thoroughly and drain all fluid from pump. Loosen screws securing cover to housing, then lay pump assembly on a bench and remove housing cover screws. Lift housing assembly from pump cover and lift pressure plate off dowel pins. Remove "O" ring from pressure plate. Remove coupling shaft, then remove pump ring from dowels in pump cover. Remove both large and small "O" ring seals from grooves in pump cover. Remove shaft seals by prying with a screwdriver. Remove roll pin retaining flow control valve in housing and remove plug, "O" ring, control valve, and spring. *NOTE - If plug or valve is stuck in pump housing cov r, it can be removed by tapping end of housing on a pi c of wood.* Remove "O" ring from plug.

INSPECTION: Wash all parts in clean solvent and blow dry with air. Inspect all parts for wear, scoring, nicks, or burrs. Replace necessary parts. Check vanes for fit in rotor slots. Vanes should slide freely, but snugly in slots. Replace rotor or vanes if excessively worn. Inspect surface of cam ring for wear or scoring. Replace ring, rotor and vanes if any one of the three components show wear or scoring. Inspect oil passages for obstructions. Check pressure plate and contact area on body for wear or scoring and replace necessary parts. Do not resurface these faces. Replace valve assembly if damaged. Do not disassemble valve. Check freedom of control valve in housing bore.

REASSEMBLY: Install spring in housing, then install control valve in bore with hole in control valve toward spring. Install new "O" ring on plug and install plug, retaining it in place with the roll pin. Check condition of bronze fitting seats in pressure and return ports. If damaged, remove them with an E-Z-Out and replace with new inserts. Lubricate all parts with Automatic Transmission Fluid Type "A" as they are installed. Install oil seals with lips inward, on body and cover, and press seals into housing and cover using Tool 33623-C. Install large "O" ring seal on face of cover and install small "O" ring in inlet oil passage in cover. Install dowel pins in cover, then install coupling shaft in cover, using Tool 33623-D. Place rotor on shaft with counterbored spline toward cover side and place vanes in rotor with rounded edge toward outside of rotor. Position cam ring on dowels with arrow on outer surface of ring pointing in direction of pump rotation. (Holes in ring must line up with kidney shaped holes in cover). Install "O" ring on rear of pressure plate and position pressure plate on dowel pins which extend through cam ring. Place housing over coupling shaft, using Tool 33623-D to prevent damage to seals. Install capscrews and tighten to 15-18 ft. lbs.

INSTALLATION: Reverse removal procedure and note the following: Tighten mo unting bolts to 10-13 ft. lbs., crankshaft damper bolt to 80-100 ft. lbs., and hose end nuts to 20-30 ft. lbs. Fill reservoir and bleed system.

EDSEL, LINCOLN, MERCURY (CRANKSHAFT MTD.) POWER STEERING PUMP

CHRYSLER, DE SOTO, DODGE, PLYMOUTH SINGLE ROTOR TYPE

DESCRIPTION: Single rotor type with an integral flow control valve. Pump is mounted on rear end of generator and is driven by generator shaft.

►*PUMP COUPLING NOTE:* Two different types of pump drive coupling have been used and special Pump and Generator must be used with each type coupling (special shaft used with each coupling).

1) Rubber Insulated Coupling–Oilite coupling flanges are pressed on generator and pump shafts and retained by special "thread locking" type capscrew and plain washer (lockwashers should not be used with these screws). A rubber insulator and insulator sleeve are installed between the coupling flanges to transmit the drive.

2) Metal Tongue Coupling–Tongue-and-slot type metal coupling. Coupling members are retained on shaft ends by a retaining ring and slide off after ring removed.

OVERHAUL OF PUMP: *CAUTION*–Cleanliness is extremely important when working on hydraulic pump. Pump should be thoroughly cleaned before disassembling, work bench should be covered with clean paper, and all parts should be kept in clean kerosene until reassembled to protect them from dirt and corrosion.

Removal of Reservoir From Pump:

1) Remove cover assembly from reservoir, lift out filter element and drain oil from reservoir.

2) Install the small tapered plug Tool C-3117 and the large tapered plug Tool C-3118, into the two holes that permit passage of oil to pump (this will prevent dirt entering pump).

3) Remove the four reservoir-to-pump attaching screws and lift reservoir from pump, being sure not to lose one large rubber "O" ring and five small rubber "O" rings which are used as gaskets between pump and reservoir.

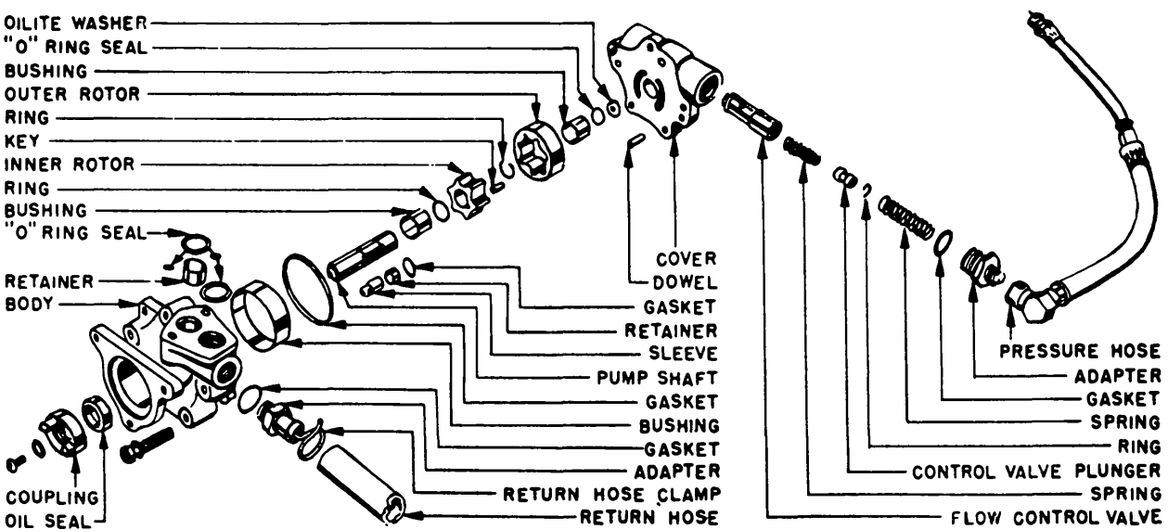
Disassembly ("Single Rotor" type): Remove coupling lock screw, then remove coupling. Install pump in vise with protective copper jaws. Remove five body-to-cover attaching bolts, then remove cover. Remove shaft and rotor assembly, then "O" ring seal and "oilite" thrust washer in bottom of pump shaft hole.

Bushing & Seal Replacement–*NOTE*–New seal should always be installed whenever bushing replaced. Replace bushing and seals as follows:

Pump Cover Shaft Bushing–Place pump body in vise with protective copper jaws, install Tool C-3185, tap threads into bushing with outer section of tool, using an open end or adjustable wrench. After tool threaded into bushing sufficiently, screw T handle section of tool into hole until tool bottoms in cover, remove bushing. To install, drift bushing into place with Tool C-3233.

Pump Body Shaft Bushing–Place pump body in vise with protective copper jaws, mount pump cover to pump cover to pump body, install attaching bolts. Install Tool C-3185 in cover bushing hole, thread tool into housing bushing, remove bushing and seal. To install, mount bushing to Tool C-3235 and drift bushing into place.

Outer Rotor Babbitt Bushing–Remove pump cover from pump body. Thread Tool C-3214 into pump body using adapter Tool C-3234, remove bushing. To install, drift bushing into place with Tool C-3251.



Pump Shaft Oil Seal Replacement–With pump body securely clamped in vise with protective copper jaws, mount seal to Tool C-3230, drive seal into place.

Cleaning & Inspection: Clean all parts thoroughly in solvent and blow dry with compressed air. Wash bearings in clean kerosene and dry by blowing air through bearing (*CAUTION*–do not spin bearing with air). Inspect bearings for wear or roughness and replace if they do not rotate freely. Inspect babbitt rings in pump body for wear or scoring. Inspect rotors and pump shaft for wear, scoring, or burrs (remove burrs with a fine stone or crocus cloth). Check end clearance of rotors by installing them in pump body and using a feeler gauge to measure clearance from rotor to straightedge placed on face of body. End clearance limits are .001-.0017". Check valve plunger.

►*NOTE:* If rotors badly scored, or worn beyond limits given above, install complete new pump assembly.

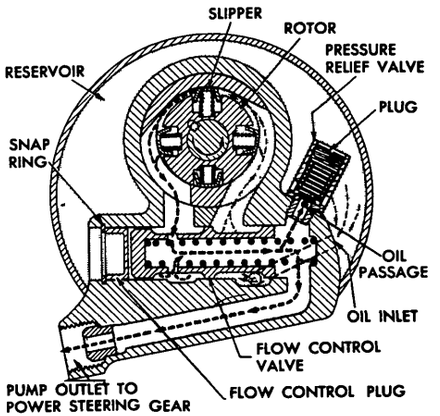
Reassembly ("Single Rotor" type): Use NEW "O" ring seals and gaskets. Lubricate all parts with clean SAE 10W engine oil, coat "O" ring seals with Lubriplate. Assemble pump as follows: Install flow divider valve (ported end first) into pump body. Insert small spring plunger and ring, using Tool C-3229. Install large spring, gasket and adapter. Tighten adapter to 45-50 ft. lbs. torque. Install shaft protector thimble Tool C-3228 in pump body until tool bottoms, install rotor shaft assembly, using care not to damage babbitt bushings when installing rotor. Position "O" ring seal in body. Place cover in position, installing attaching bolts and washers. Tighten bolts to not more than 17 ft. lbs. Install coupling flange on pump shaft, then special lock screw and washer. Hold coupling with Tool C-3227 and tighten to 10-12 ft. lbs. torque.

Installation of Reservoir on Pump: Install one large circular section "O" ring, and five (5) small "O" rings which are used as gaskets between reservoir and pump. Install small tapered plug, Tool C-3117 and large tapered plug, Tool C-3118, into the two passage holes in bottom of reservoir. Insert the two pilots, Tool C-3116, into matching screw holes of reservoir and pump and install reservoir to pump. Install the four attaching screws and tighten to 7-12 ft. lbs. torque.

HYDRAULIC PUMP (SINGLE ROTOR TYPE)

Form 58 A

CHRYSLER, DE SOTO, DODGE, PLYMOUTH, VALIANT "SLIPPER" TYPE



►CHANGES, CAUTIONS, CORRECTIONS

►*PUMP REPLACEMENT PARTS NOTE:* Parts for pumps having the "Load Reaction Belt Tensioner" are not interchangeable with conventional type pumps.

DESCRIPTION: Constant displacement rotary type, having spring loaded "slippers" operating in slots of rotor. A pressure relief valve in the pump limits maximum pressure to 850-950 psi.

REMOVAL: Remove drive belt, then drain reservoir and pump. Disconnect hoses and remove screws attaching pump bracket to water pump housing. Remove pump.

DISASSEMBLY: Clean exterior of pump assembly before starting disassembly, then drain all fluid from pump and reservoir. Remove front and rear brackets and carefully pry reservoir from pump. Reinstall front bracket to pump to be used as a holding fixture. *CAUTION - Use spacers between pump b dy and bracket so bolts do not bottom in pump h using.* Use Tool C-3615 and remove pulley. Remove relief valve assembly and gasket. *NOTE - Reli f valve is servic d only as an assembly.* If necessary to remove flow control valve, remove control valve snap ring, then remove flow control valve plug by threading a tap (Tool C-3655) into plug. With tap securely installed in plug, install tool spacer and nut over tap and tighten nut while holding tap from turning. Plug will be forced from housing. *CAUTION - Flow control valve is spring loaded and caution should be used when removing plug.* Thread puller portion of Tool C-3642 into oil seal to engage metal portion of seal and remove seal from pump insert. *NOTE - Further disassembly of pump is not recommended as component parts of pump other than reservoir, "O" ring and relief valve are not serviced separately.*

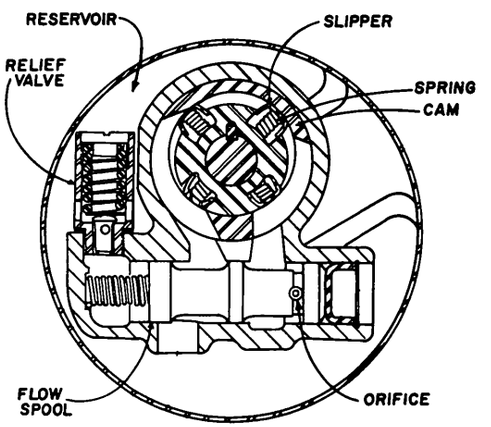
"SLIPPER" HYDRAULIC PUMP ASSEMBLY

INSPECTION: Clean all parts in clean solvent, discard body-to-reservoir "O" ring and pump shaft oil seal. Check flow control valve for burrs and scratches. *NOTE - Flow control valve must operate freely in bore. Small scratches can be carefully removed with crocus cloth. DO NOT round off edges of valve as th y must be square.* If bore of flow control valve is scratched or worn, replace complete pump assembly.

REASSEMBLY: Install flow control valve spring, valve and a new valve plug and snap ring. Drive valve plug with Tool C-3233 far enough into bore to install snap ring, then drive snap ring and plug with Tool C-3233 until snap ring seats in groove in housing bore. Install relief valve and gasket assembly. Install oil seal with Tool C-3640 (lip of seal must face toward pump body and top of seal must be flush with front insert). Support pump body in holding fixture, Tool C-3643 so that pressure will be absorbed by lower end of pump shaft, then install pulley with an arbor press until pulley hub is flush with end of shaft. Coat large "O" ring with lubriplate and install in outer groove in pump body. Install reservoir gasket, reservoir, and reservoir attaching screws. Tighten screws to 10 ft. lbs. and install pump brackets.

PUMP PRESSURE TEST: *See "Chrysler, DeSoto, Dodg , Plymouth (Constant Control) Power Steering".*

RAMBLER "SLIPPER" TYPE



Rambl r Seri s 6001 & 6010 (1960)

DESCRIPTION: Constant displacement rotary type with spring loaded slippers operating in slots in rotor. An integral pressure relief valve in pump limits pressure to 850-950 lbs.

REMOVAL: Remove fan belt and place a suitable container under pump, then disconnect pressure and return hoses. *CAUTION - Cap hose fittings to prevent loss of oil from steering system.* Disconnect power steering pump bracket from engine and remove pump assembly.

DISASSEMBLY: Drain reservoir and pump, then clamp pump bracket in a vise. Mark position of reservoir in relation to pump body, then remove reservoir attaching screw and carefully pry reservoir off pump body. Remove pulley with a suitable puller, then remove relief valve and gasket. *NOTE - Relief valve is serviced nly as a complet assembly.* Thread puller portion of Tool J-8647 into shaft oil seal far enough to engage metal lip of seal, then hold puller body and turn center screw to force seal from pump insert. If outlet fitting requires replacement, remove with an "easy-out" (Tool J-8659). *NOTE - Furth r disassembly of pump is not recommended as pump components are not serviced separat ly.*

INSPECTION: Wash all parts in solvent and inspect casting and pump components for visible damage. Discard reservoir "O" ring seal, pump shaft oil seal, outlet fitting (if removed), and relief valve gasket.

RAMBLER HYDRAULIC PUMP

REASSEMBLY: Lubricate all parts with Automatic Transmission Fluid, then install relief valve and new gasket. Install pump shaft seal with Tool J-8648 (lip of seal towards pump body), then press on metal part of seal until top of seal is flush with front insert. Install pulley with a heavy duty arbor press while supporting lower end of pump shaft with Tool J-8649. *CAUTION - Make sure that pressure is absorbed by pump shaft.* Pulley should be pressed on until distance from center of groove (outer groove on double groove pulleys) to face of bracket mounting boss on pump is 1 19/32" (single groove pulley); 2 1/32" (double groove pulley). Lubricate large "O" ring seal and install in pump body groove. Position reservoir gasket on back of pump and hold it in place with a dab of grease, then install reservoir in previously marked position. Tap into place with a plastic hammer, then install screw and tighten to 10 ft. lbs. Insert outlet fitting in outlet hole using finger pressure only. *NOTE - When pressure hos is installed, hose fitting will press outlet fitting into place.*

INSTALLATION: Reverse removal procedures and adjust drive belt, then bleed system (see below)

BLEEDING SYSTEM: Fill reservoir to bottom edge of filler neck with Automatic Transmission Fluid Type "A", then start engine and run for ten minutes, maintaining an adequate supply of oil in reservoir. *CAUTION - Do not turn steering wheel during warm-up period.* Raise front wheels off floor, then turn steering wheel full right and full left several times. *CAUTION - Do not hold wheels against stops for any length of time.* Check and refill reservoir and inspect system for leakage.

PUMP PRESSURE TEST: *S "Monroe Linkag Typ P w r St ring".*

EATON ROTOR TYPE

►CHANGES, CAUTIONS, CORRECTIONS

►***OIL PUMP CAUTION—Always cap or plug all pump ports whenever oil lines disconnected and use extreme care to keep all pump parts clean.***

►1957-58 *EATON POWER STEERING PUMP NOTE:* Pump shaft is now carried on two bushings which replace the former ball bearing. Bushings in 1957 and later pumps are integral with the housing and cannot be replaced. If bushings become worn or scored, replace complete housing assembly.

EATON OIL PUMP: Disassembly. Thoroughly clean exterior of pump before removing plugs or disassembling parts. Then proceed as follows:

1) Remove reservoir cover and gasket, then drain reservoir. Remove filters, reservoir, then separate pump cover from pump body. *(CAUTION—*Before removing cover place pump with shaft end down to prevent falling out of rollers).

2) Turn pump body over and slowly rotate shaft so that rotors fall free, remove rotors and drive key from shaft. Remove "O" ring seals from pump body.

3) Remove bearing snap ring from recess in body using snap ring pliers, tap lightly on end of shaft, remove shaft and bearing assembly from pump body. Remove inlet fitting and seal from pump body and valve cap adapter seal and orifice plate from cover, then remove flow control valve spring and damper by depressing relief valve slightly and removing snap ring with snap ring pliers.

4) Remove spring, relief valve and flow control valve from cover.

Cleaning & Inspection: *CAUTION—*Do not wash shaft and bearing assembly in cleaning solvent which may wash lubricant out of sealed bearing (wipe bearing and shaft assembly with clean cloth only). Clean all other parts with clean kerosene or solvent, wipe dry with clean lint-free cloths. Inspect bearing in cover and replace if worn or noisy. Inspect shaft for wear and bearing for wear, roughness, or noisy operation (if either part requires replacement, press bearing off and on shaft in an arbor press). Inspect shaft seal in pump body for wear or damage (if seal requires replacement, drive old seal out with a punch, press new seal squarely into place with spring-loaded edge inward). Inspect valves for nicks, scores, or scratches and also inspect valve bores in pump cover (minor nicks may be removed by stoning). Check valve clearance in cover, valves should be free in bores and clearance must not exceed .0025". Inspect valve springs and replace if weak or distorted. Inspect cover and body for wear caused by rotors, replace if surfaces scored or worn. Inspect both rotors as detailed below and replace both rotors if either part worn or scored.

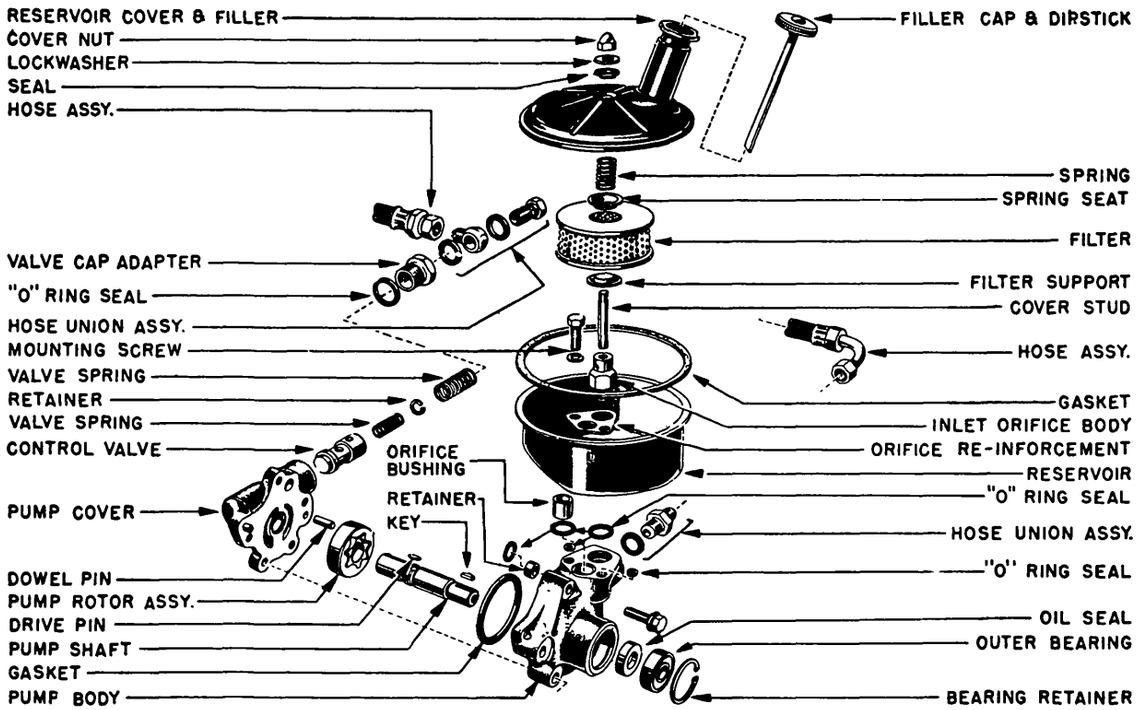
Inner & Outer Rotor Clearance—With one tooth of inner rotor fully meshed in outer rotor, measure clearance between rotors at opposite inner rotor tooth using a feeler gauge. Repeat this check for each rotor tooth. Replace rotors if clearance exceeds .006" (Packard), .008" (Others).

Outer Rotor Clearance in Pump Body—Insert outer rotor in pump body, check clearance between outer diameter and bushing in body with feeler gauge. Replace pump body if clearance exceeds .008".

Rotor Side Clearance—Install both rotors in pump body, place straightedge across face of pump, use feeler gauge to measure clearance between rotors and straightedge. Replace pump body if clearance exceeds .0025".

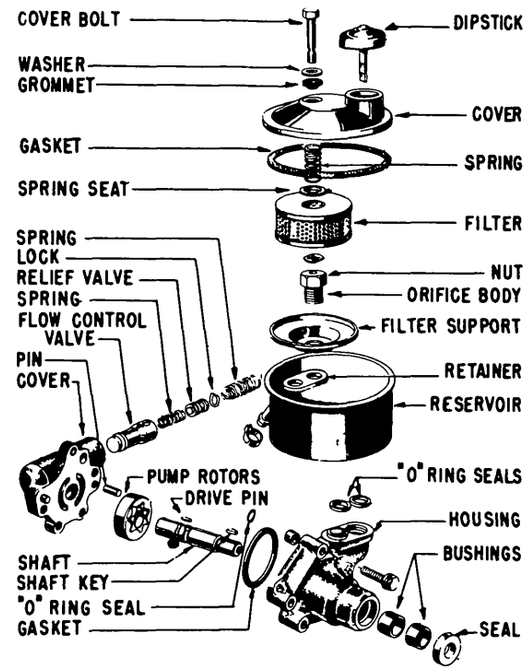
Spring Tension (Relief Valve) 32 lbs. at 1.18"

Spring Tension (Flow Control Valve)—16 lbs. pull plus or minus 1½ lbs. at 1.20".



Reassembly—If removed, install new oil seal in pump body bore with lip toward rotors. If ball bearing removed from pump new bearing should be pressed on with arbor press until it butts against shoulder on pump shaft. Using all NEW seals and gaskets and lubricating all moving parts with Automatic Transmission Fluid Type A, proceed as follows:

1) Install assembly of pump shaft and bearing in pump body bore. Install ball bearing retainer. Position drive pin or key in pump shaft slot.



2) Install rotor assembly. If valve subassembly disassembled, install relief valve spring, relief valve, and retaining ring in flow control valve body. Compress assembly into body until there is sufficient room for installing ring in valve body groove, install retaining ring.

3) Install orifice plate in pump body bore. Install flow control valve spring. Install new gasket on hose adaptor valve cap, install and tighten cap. Install new gasket at pump body pressure port and a pump body-to-cover gasket.

4) Install pump cover on pump body. Install screws and torque tighten to 30-35 ft. lbs. (Nash & Packard 25-30 ft. lbs.) Install new "O" ring gaskets on top of pump body, install reservoir and filter.

EATON ROTOR TYPE PUMP (BALL BEARING TYPE)

EATON ROTOR TYPE PUMP
(INTEGRAL BUSHING TYPE)

EATON ROLLER TYPE

►CHANGES, CAUTIONS, CORRECTIONS

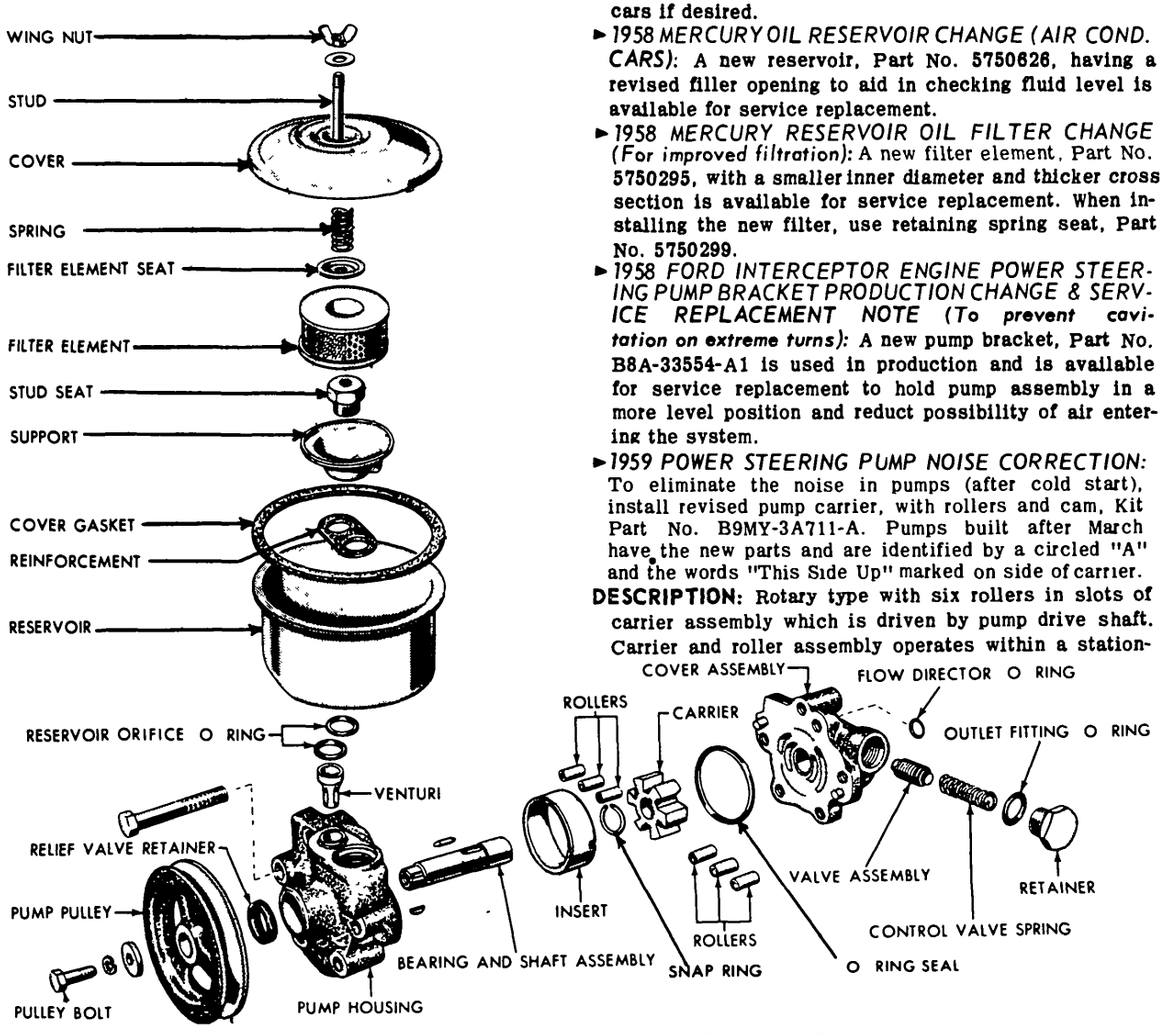
►*1958 EDSEL & MERCURY PUMP NOTE: "Vane" type crankshaft mount d pumps also used on some models.*

►*1958 PUMP PRODUCTION CHANGE:* Internal design of pump was changed in early production for improved operation. Later pumps are marked with either a green or yellow stripe of paint across top of pump next to reservoir.

►*1958 EDSEL OIL RESERVOIR LEAKAGE CORRECTION:* Clean gasket surface, then apply Perfect Seal Compound, Part No. B6A-19554-A, sparingly to cover gasket surface and allow to partially dry. Install new gasket, Part No. AE-33535-A on cover, then position cover and gasket on reservoir in a straight down movement (do not rotate cover to seat gasket). Install washer and wing nut and tighten securely.

►*1958 LINCOLN RESERVOIR GASKET LEAKAGE CORRECTION:* Install a new "Texon" (fibre) gasket, Part No. B8A-33535-A in place of the former neoprene type gasket.

►*1958 FORD RESERVOIR COVER STUD LEAKAGE CORRECTION:* Remove reservoir cover and filter spring, then push Seal Ring, Part No. 372144-S down around stud until seal ring is on top of metal filter retaining washer. Install spring, cover, and flat washer.



►*1958 LINCOLN & CONTINENTAL RESERVOIR FILLER CAP & FILTER PRODUCTION CHANGE:* The oil filler cap and reservoir oil filter have been eliminated in later production cars. Filter can be omitted on early cars if desired.

►*1958 MERCURY OIL RESERVOIR CHANGE (AIR COND. CARS):* A new reservoir, Part No. 5750626, having a revised filler opening to aid in checking fluid level is available for service replacement.

►*1958 MERCURY RESERVOIR OIL FILTER CHANGE (For improved filtration):* A new filter element, Part No. 5750295, with a smaller inner diameter and thicker cross section is available for service replacement. When installing the new filter, use retaining spring seat, Part No. 5750299.

►*1958 FORD INTERCEPTOR ENGINE POWER STEERING PUMP BRACKET PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE (To prevent cavitation on extreme turns):* A new pump bracket, Part No. B8A-33554-A1 is used in production and is available for service replacement to hold pump assembly in a more level position and reduct possibility of air entering the system.

►*1959 POWER STEERING PUMP NOISE CORRECTION:* To eliminate the noise in pumps (after cold start), install revised pump carrier, with rollers and cam, Kit Part No. B9MY-3A711-A. Pumps built after March have the new parts and are identified by a circled "A" and the words "This Side Up" marked on side of carrier.

EATON ROLLER TYPE HYDRAULIC PUMP ASSEMBLY

DESCRIPTION: Rotary type with six rollers in slots of carrier assembly which is driven by pump drive shaft. Carrier and roller assembly operates within a stationary eccentric insert causing a pump action similar to "vane" type rotary pumps.

DISASSEMBLY: Clean exterior of pump thoroughly before disassembly, then drain as much fluid as possible from pump and reservoir assembly. Clamp pump adjusting bracket in a vise, then on Ford 6 Cyl. models, remove reservoir adapter. On other models, remove cover and lift filter out of reservoir (if so equipped). Remove center stud, then remove support bolt (stud seat), and support, and remove reservoir. Remove 2 orifice "O" rings from top of pump. Remove pulley and pulley key from carrier shaft, then remove all bolts from pump. Separate bracket, pump housing, and housing cover and lift cover vertically from housing to prevent internal parts falling out. *NOTE - If necessary, tap parts gently with a s ft hammer to loosen them.* Remove "O" rings from flow director and carrier insert. Lay a straightedge across pump housing next to carrier shaft and measure carrier endplay with a feeler gauge. If endplay exceeds .0015", replace worn parts. Remove six rollers, then pull out the carrier and shaft very carefully to avoid damage to parts or oil seal. *NOTE - Carrier eccentric insert sh uld only be removed if it is to be replaced.* Remove carrier retaining ring from shaft, and remove pin. Remove relief valve retainer from cover and remove "O" ring from retainer. Remove valve assembly spring from bore in cover, then slide valve out of bore.

INSPECTION: Clean all parts with solvent and dry with a lint free cloth. Inspect pump housing and cover for wear caused by turning of rollers and carrier. Check bushings in housing and cover for wear or scores and replace housing or cover if necessary. Inspect other parts for wear or damage and replace necessary parts. *NOTE - Do not instdll a carrier, roller or the insert alone; these parts are furnished in a kit and all parts should be installed.* With valve and bore dry, insert valve in housing and check for free movement in bore. Remove any burrs from valve with crocus cloth. Inspect carrier shaft seal in housing and if necessary, remove seal with a punch (do not damage bushing). *NOTE - Do not remove seal except for replacement. If seal removed, a NEW seal must be installed.* To install a new seal, coat lip with lubriplate, then position seal in bore with lip facing toward carrier chamber. Press seal into housing until it seats firmly and evenly against shoulder in bore.

REASSEMBLY: Install key, pulley, washer, and retaining bolt on shaft and tighten bolt finger tight. Carefully insert shaft assembly through housing, being careful not to damage seal in cover, then install shaft pin and slide carrier onto shaft. Install retaining ring and rollers. Remove retaining bolt, washer, pulley, and key from shaft. *CAUTION - Be sure shaft does not move back and forth in housing as it will damage the seal.* Install valve assembly in bore and install a new "O" ring on pump valve retainer, then install retainer in pump housing cover. Tighten to 30-35 ft. lbs. Place a new "O" ring in groove around insert in pump housing.

CONTINUED ON NEXT PAGE

EATON ROLLER TYPE (Continued)

and install a new "O" ring (flow director) in face of housing. Fasten pump housing and cover together, then install pump on bracket. Install all bolts and tighten to 20-25 ft. lbs. Install key, pulley, washer, and retaining bolt on carrier shaft. Tighten retaining bolt to 15-20 ft. lbs. *CAUTION - Carrier shaft should turn freely when bolt is properly tightened.* Install new "O" rings in grooves on top of pump housing, then install reservoir adapter (Ford 6) and tighten nut to 30-35 ft. lbs. On other cars, hold reservoir on pump housing and install reinforcement in reservoir with ears of reinforcement facing upward over outer hole in reservoir. Install filter element support and bolt and tighten bolt securely. Place filter element on bolt (if so equipped), then install a new gasket around inside of cover. Install a new seal under head of cover retaining bolt. Install cover and tighten bolt securely. Make sure gasket is seated evenly and tightly around edge of reservoir.

INSTALLATION: Reverse removal procedures and note the following: On Lincoln & Continental, make sure there is 1/16" to 1/8" clearance between power steering pump bracket and engine front support bracket.

EATON "ROLLER" TYPE (CRANKSHAFT MOUNTED)

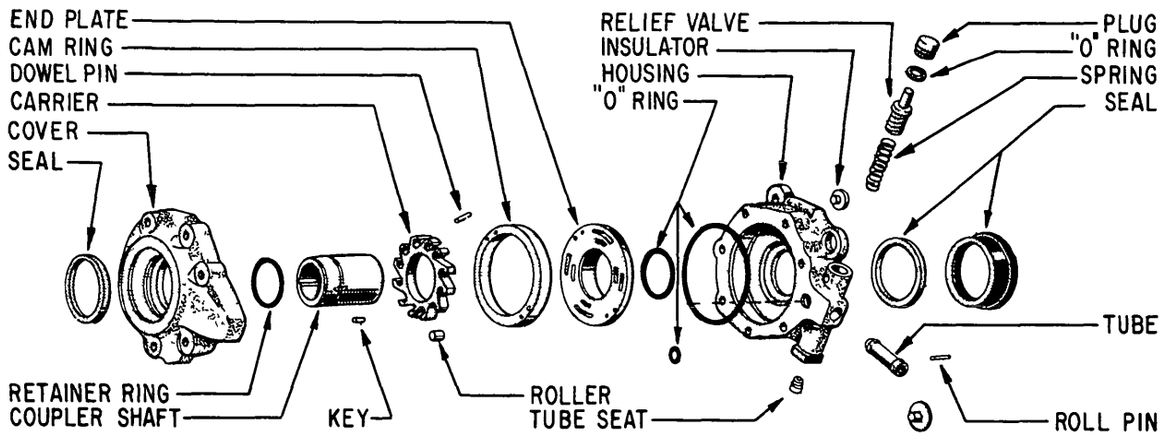
DESCRIPTION: Constant displacement "roller" type with an integral pressure control valve assembly. Pump assembly is mounted on front of engine and is keyed to engine crankshaft. The fluid reservoir is remotely mounted on forward end of left hand cylinder head, and is connected to pump by flexible hose.

►*HYDRAULIC PUMP IDENTIFICATION NOTE:* The later "Roller" type pumps can be identified by the pressure hose being connected to bottom of pump housing instead of to side of housing as on earlier "Vane" type pumps.

►*1960 "VANE" TYPE PUMP REPLACEMENT (WITH "ROLLER" TYPE) NOTE:* When replacing vane type pump with roller type it will be necessary to shim the water pump outward with spacers and replace the pressure hose with a currently used hose. Install water pump spacer between two gaskets at both sides of water pump-to-engine block mountings.

PRESSURE TESTING: Remove pressure hose from pump and install Adapter 3500-C in pump and in open end of hose, then connect Gauge, Tool 3500-E between adapters. Open shut off valve on gauge, then start engine and bring oil to normal operating temperature. With engine at idle speed, turn steering wheel to full right and full left and check pressure. *CAUTION - Hold wheels at stops only long enough to obtain pressure reading.* Gauge should read between 800-1075 lbs. (Mercury), 1000-1200 lbs. (Lincoln). If pressure is less than minimum, close valve at gauge and recheck pressure. If pressure is still low, pump is not operating properly. If pressure increases, internal leakage is indicated in steering system.

REMOVAL: Remove radiator and hoses, then remove generator belts. Drain power steering system and disconnect hydraulic fittings, then remove crankshaft damper and key with Tool 6306-AG. Remove two pump attaching bolts and slide pump off crankshaft. *NOTE - If pump does not slide off crankshaft easily, install two long bolts in pump body and pull pump from shaft with same tool used to remove damper.*



DISASSEMBLY: Drain oil from pump, then clamp pump in a vise and loosen capscrews securing cover to housing. Remove pump from vise and remove capscrews, then remove cover assembly from body. Remove "O" ring from cover assembly endplate and remove the two fillister head screws. Remove endplate from cover assembly and lift cam ring off dowel pins. Remove carrier and rollers from coupler shaft and remove drive key. Remove dowel pins from cover. *NOTE - Do not remove snap ring from coupler shaft unless ring is damaged.* Remove both large and small "O" rings from grooves in pump body and shaft seals from body and cover. *CAUTION - Do not disturb control valve unless trouble is indicated in this assembly.* If necessary to remove control valve, remove roll pin retaining flow control valve in pump body, then remove plug and "O" ring, control valve, and spring. *NOTE - If plug or valve are stuck in body, they can be removed by tapping end of body on a piece of wood. Remove "O" ring seal from plug.*

INSPECTION: Wash all parts in solvent and blow dry with air. Inspect faces of body and cover for nicks and burrs. Inspect coupler shaft for wear and make sure finished surfaces of shaft are free from scores, nicks or burrs. Replace shaft if damaged on outside diameter or if internal keyway is damaged. Inspect carrier, rollers, and cam ring for wear or scoring. *CAUTION - Carrier, rollers, and cam ring must be replaced as a complete unit if any part is worn or scored.* Inspect oil passages in cover for obstructions and check valving surfaces (area where carrier and rollers contact) for scoring and wear. Replace endplate assembly if necessary. Inspect valve for scores, nicks, or burred edges. Check for freedom of movement of control valve in body bore. Replace valve if damaged. *CAUTION - Do not disassemble control valve.*

REASSEMBLY: If control valve was removed, install spring in body bore, then install valve with small sensing hole toward spring. Install a new "O" ring seal on plug and install plug, retaining it in place with a roll pin. *CAUTION - Plug seal is only 1/8" smaller in diameter than the bypass seal. Do not interchange these seals.* If tube connection seat is damaged, replace with a new insert. *NOTE - As following parts are assembled, lubricate with Automatic Transmission Fluid.* Install oil seals with lips inward on body and cover, then install coupling shaft in cover (use Tool 33623-D to prevent damage to oil seal), then install drive key in shaft. Install dowel pins in cover, noting that spacing between dowel pin hole and screw hole is different on opposite sides of pump cover. Place carrier on coupling shaft with counterbored inner diameter toward cover so that it goes over shaft snap ring and is indexed with drive key. Place rollers in carrier, then position cam ring on dowel pins with chamfered edge up. Position endplate assembly on dowel pins and install the two fillister head screws and tighten to 20 inch pounds. Install "O" ring seal on cover and install large "O" ring seal in groove on face of body and the small "O" ring seal in groove at oil pump inlet hole. Place body assembly on coupling shaft (use Tool 33623-D to prevent damage to oil seal). Install capscrews and tighten to 15-20 ft. lbs.

INSTALLATION: Clean crankshaft and replace key if damaged or worn. Install rubber insulators in pump housing and check front cover seal for proper positioning, then slide pump on shaft. Install rubber insulators, mounting bolts and washers and tighten mounting bolts to 10-13 ft. lbs. Install pressure and inlet hoses on pump and tighten pressure hose nut to 20-30 ft. lbs. *NOTE - To prevent sound transmission, make sure hose does not touch body sheet metal.* Insert key in crankshaft and install pulley. Tighten pulley bolt to 70-90 ft. lbs. Install and adjust generator belt, then replace radiator and hoses. Fill reservoir and bleed system (see below).

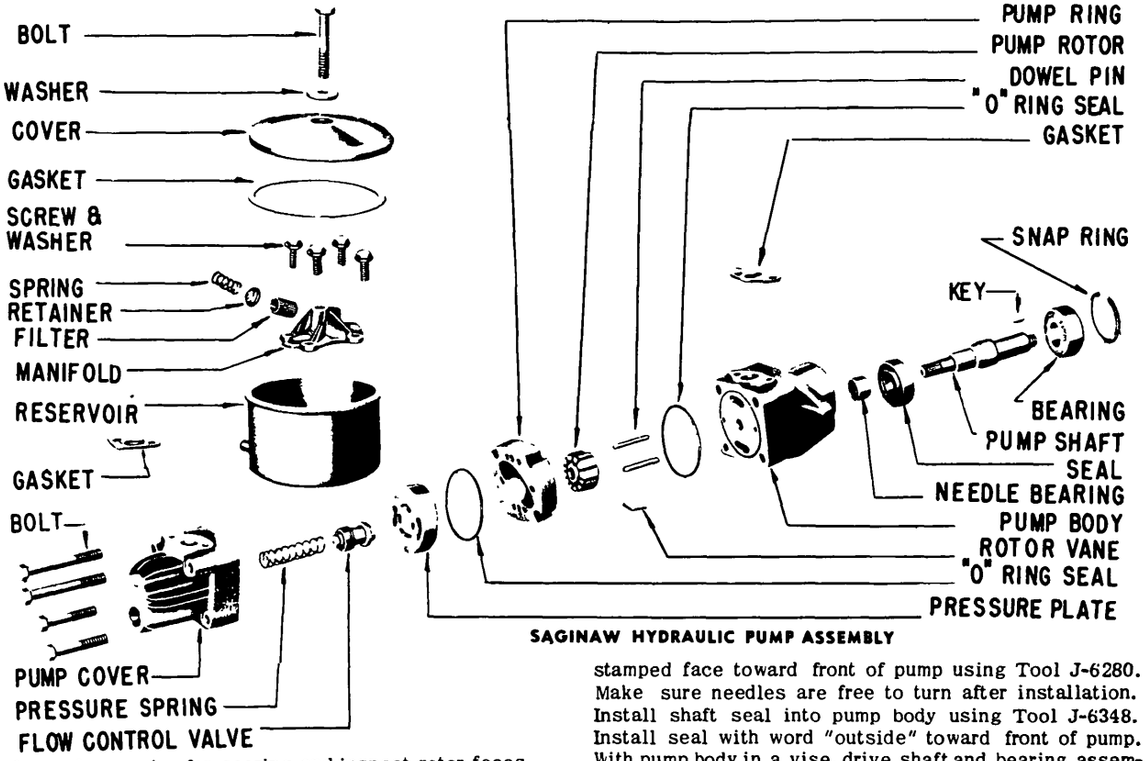
BLEEDING SYSTEM: Start engine and run at idle speed. *NOTE - Do not turn steering wheel.* When reservoir is free of foam (inspect with a light), rotate steering wheel from stop to stop to remove air from hydraulic system, then refill reservoir. Replace cover and check system for leakage.

EATON ROLLER TYPE POWER STEERING PUMP (CRANKSHAFT MOUNTED)

SAGINAW VANE TYPE

DESCRIPTION: Constant delivery vane type pump with an integral flow control valve and a pressure regulator valve. Pump is belt driven from engine crankshaft.

►CHANGES, CAUTIONS, CORRECTIONS



►*1956 BUICK POWER STEERING PUMP RESERVOIR VENT NOTE:* Aluminum and steel vent washers have both been used under the reservoir cover bolt. To prevent plugging the vent, the aluminum washer must be installed with the vent groove downward. The steel washer must be installed with the vent groove upward.

►*1956 CADILLAC PUMP SHAFT SEAL PRODUCTION CHANGE:* A new seal with same part number (5683898) has been released and is used in production beginning after Engine No. 021850. New seal has 30° angle on vacuum seal lip which reduces the possibility of the lip being torn, causing air leakage and a noisy pump.

►*1956 CADILLAC POWER STEERING PUMP PRESSURE REDUCTION (To eliminate a squealing noise):* Pressure has been reduced to 875-975 lbs. Pump pressure can be reduced in the field by installing a shim, Part No. 5683875 under the screw head on control valve. Each shim used will reduce the pressure approximately 100 lbs. Two shims may be used if necessary, however, check the pressure before and after installation to make sure that cut-out pressure remains above 750 lbs.

DISASSEMBLY (Saginaw): Remove reservoir cover bolt, flat washer, and reservoir cover with gasket. Remove filter screen, filter retainer and filter spring by pushing retainer back against spring. Remove four reservoir-to-pump bolts and remove reservoir and cork gaskets. Remove four pump cover-to-pump body attaching screws *(NOTE* - Do not clamp on front hub of pump as this may damage bearing housing). Lift pump cover with flow control valve assembly and spring from assembly (be careful that pump flow control assembly does not drop out). Mark position of pressure plate and remove plate from dowel pins. Mark position of pump ring in relation to pump body and remove ring from dowel pins *(NOTE* - Arrows on outer edge of pump ring point in direction of pump rotation). Remove ten pump vanes and remove pump rotor. Remove dowel pins from pump body. *(NOTE* - Any further disassembly should be avoided unless parts are dirty or repair operations are necessary on any of the remaining parts). Remove shaft bearing retainer snap ring from front hub of pump body using Tool J-4245. Remove drive shaft with large sealed bearing by lightly tapping on splined end. Remove oil seal from body with a long punch inserted through large hole in machined face of body. If it is to be replaced, remove inner needle bearing from pump body using Tool J-6279. Remove key from shaft. If outer bearing is to replaced, remove by pressing it from pump shaft.

CLEANING & INSPECTION: Wash all parts, except the drive shaft bearing (lubricant seal in bearing) in a solvent. Inspect "O" ring seals and gaskets. Replace seals if cut, or distorted. Inspect pump cover flow control valve bore for scores and wear. Inspect flow control valve for free movement in its bore. Inspect all passages in cover and body for obstructions or dirt. Inspect pressure plate for scoring. Inspect contour

SAGINAW HYDRAULIC PUMP ASSEMBLY

surface of pump ring for scoring and inspect rotor faces for metal pick-up or scoring. Check vanes for bind in slots of rotor. Inspect face of pump body for scoring or wear. Inspect drive shaft seal surface for scratches and wear. Inspect drive shaft inner and outer bearings for roughness or noisy operation.

►*FLOW CONTROL SERVICING NOTE:* If flow control valve is stuck, dislodge by jarring front of pump cover. If pump cover control valve bore is worn or scored, replace pump cover. If necessary to clean or repair pressure relief valve, grip flow control valve by small hub on end of valve and remove orifice screw, shims, ball, plunger and spring. If internal parts are found to be worn or scored, replace assembly. *NOTE* - The flow control valve assembly is calibrated at the factory and components of assembly cannot be serviced.

►*PUMP INTERNAL GROUND SURFACE NOTE:* If pressure plate, pump body, rotor or pump ring is scored, the following corrections can be made. Using a flat surface and lapping compound, lap the scored surfaces until they are smooth. *NOTE* - Thoroughly clean in solvent after lapping.

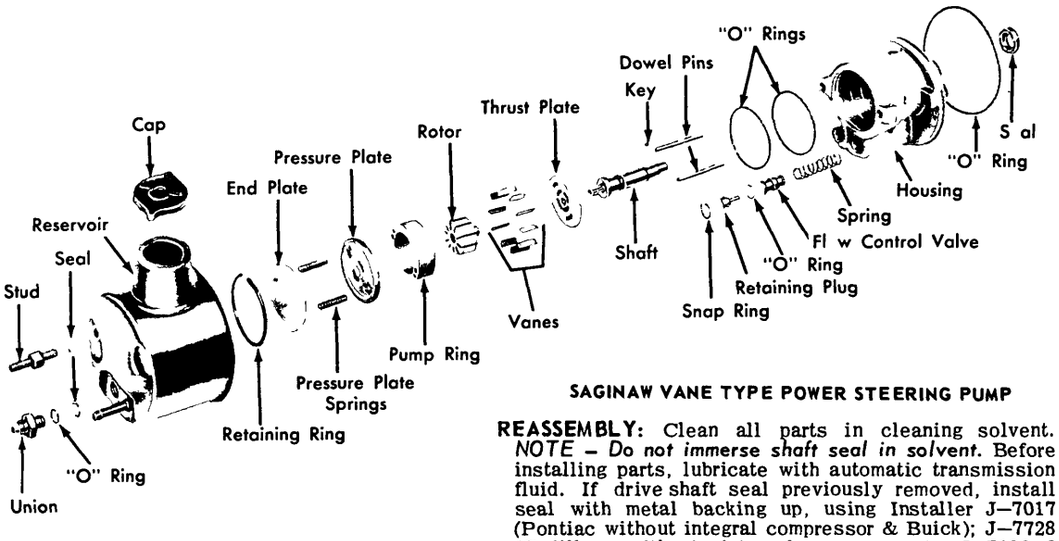
REASSEMBLY: *(NOTE - Before reassembling, make sure all parts are clean. Lubricate "O" rings and all moving parts as assembled).* Press large sealed bearing over threaded end of drive shaft with stamped face of inner race toward front of pump. Install key into shaft keyway, supporting shaft on opposite side when installing key. Install needle bearing into pump body with the stamped face toward front of pump using Tool J-6280. Make sure needles are free to turn after installation. Install shaft seal into pump body using Tool J-6348. Install seal with word "outside" toward front of pump. With pump body in a vise, drive shaft and bearing assembly into pump body. Install shaft bearing retainer snap ring. Install "O" ring in groove of pump body and install dowel pins. Tap lightly if necessary. Install rotor over splined end of drive shaft (Assemble rotor with countersunk side toward front of pump and be sure rotor is free on splines). Install vanes in rotor slots with radius edge toward outside. Install pump ring on dowels and position correctly according to scribed marks *(NOTE*- Arrow on outer edge of pump ring points to rotation of pump). Install pressure plate on dowel pins *(NOTE* - Pressure plate must be free with no binding on dowel pins). Install "O" ring around pressure plate. Install flow control valve and spring in pump cover. Be sure that end with screw goes into bore first *(CAUTION - If valve is installed backwards, the pressure regulator valve inside of the flow control valve will not op rat and pump will build up an increasingly higher pressur which would result in breakage of the adapter in g ar housing or failure at some other point in the syst m).* Position pump cover assembly over pressure plate being careful not to pinch "O" ring. Install four cover-to-body attaching screws and tighten alternately to 25-30 ft. lbs. Install gaskets on pump body and cover. Position reservoir on pump assembly with extrusions in reservoir bottom inside the smaller gasket holes and install four bolts. Tighten to 8-10 ft. lbs. Install filter spring, filter retainer, and filter. Be sure flared end of filter retainer is toward filter. Install reservoir cover with gasket, bolt and washer. Tighten cover bolt to 7-9 ft.lbs.

SAGINAW VANE TYPE (INTEGRAL RESERVOIR)

►CHANGES, CAUTIONS, CORRECTIONS

►*1959 CADILLAC EXCESSIVE POWER STEERING PUMP PRESSURE CORRECTION: NOTE – This correction also applies to 1960 models with Air Conditioning.* Excessive pressure, indicated by a burst hose, blown seal, bent linkage, or by pump squeal and belt slippage, may be caused by a loose oil filter screen cartridge obstructing the bypass feed port. Check tightness by removing pressure hose from pump and inserting a screwdriver through central hole of fitting. Rotate screwdriver until slot in end of filter cartridge is located, then tighten as required. If excessive pressure is still evident, check pressure relief hole in flow control valve.

►*1959-60 POWER STEERING PUMP THRUST PLATE REPLACEMENT CAUTION:* Use Pump Thrust Plate, Part No. 5687321 for 1959 pumps and Part No. 5687785 for 1960 models. DO NOT USE 1959 plate in 1960 models as the drive shaft seal will be subjected to full pump pressure and will blow out.



DESCRIPTION: Vane type pump mounted on engine and driven by a belt from engine crankshaft. On some models the pump is integral with the air suspension air compressor and is driven by the compressor shaft.

REMOVAL: *NOTE – On models with integral air suspension compressor, remove power steering pump and air compressor from engine as a unit.*

Buick: Remove belt from pulley and remove pulley nut, then pull pump pulley with a three jawed puller. Disconnect return and pressure lines from pump (cap or plug all openings). Remove nuts attaching pump to rear mounting bracket, then remove the one bolt attaching rear bracket to intake manifold and remove rear mounting bracket. Remove nut attaching pump brace to cylinder head and remove brace, then remove two bolts attaching pump to front mounting bracket and remove pump.

Cadillac: (Coil Spring Cars) – Syphon fluid from pump, then disconnect pressure and return hoses at rear of pump reservoir and raise hose to prevent loss of fluid. Remove pulley nut, then loosen bolts holding pump to front and rear mounting brackets and remove drive belt. Remove pulley from pump with a suitable puller. *CAUTION – Do not hammer pulley off shaft.* Remove bolts securing pump to front mounting bracket and bolt securing rear mounting bracket to exhaust manifold, and remove pump and bracket. Remove rear mounting bracket from pump.

Cadillac: (Air Suspension Cars) – Disconnect air hoses at compressor and oil inlet and return lines from bearing plate on compressor. Syphon fluid from pump, then disconnect pressure and return hoses at rear of pump and secure hoses in a raised position. Remove pulley with a suitable puller. *CAUTION – Do not hammer pulley off shaft.* Remove screw securing compressor front support bracket to exhaust manifold and two screws securing bracket to cylinder head. Remove nuts from support bracket at rear of pump reservoir and remove pump, compressor, and front support bracket as a complete assembly. Drain fluid from pump, then remove bracket from compressor and mounting studs and union from reservoir. Rock pump reservoir back and forth and remove reservoir from housing. Remove screws securing pump to compressor, then pull pump off splined shaft. Discard "O" ring seal.

SAGINAW VANE TYPE POWER STEERING PUMP

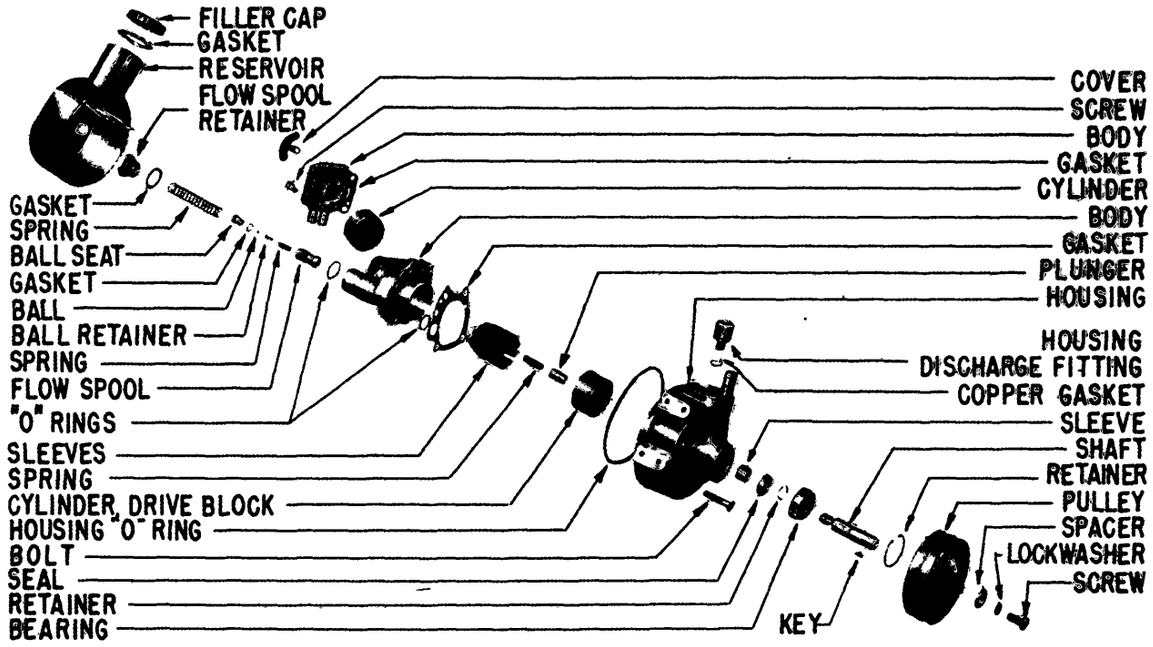
Oldsmobile & Pontiac: Disconnect holes from pump and secure ends in a raised position, then cap pump fittings. Remove pulley attaching nuts, then remove rear bracket attaching nuts and the bracket-to-manifold bolt. Loosen pump-to-front bracket attaching bolts and remove belt and pulley. *CAUTION – Do not hammer pulley off shaft.* Remove pump from front mounting bracket.

►*PONTIAC NOTE: On models with integral air suspension air compressor; remove pump and compressor in same manner as indicated for "Cadillac (Air Suspunsion Cars)" above.*

DISASSEMBLY: If not previously done, clamp pump in a vise and remove pump rear mounting stud and seal. *NOTE: In clamping pump in vise, do not exert excessive force on front hub or pump flange as pump housing may be distorted.* Remove union and seal, then rock reservoir back and forth and remove from pump housing. Rotate end plate retaining ring with screwdriver until one end of ring is across hole in pump housing, then insert a center punch through hole in housing to push retaining ring out of groove and remove ring. Remove end plate. *NOTE – End plate is spring loaded and will generally sit above housing level. If sticking should occur, a slight rocking action will free plate.* Remove pressure plate springs, then remove pump from vise and remove woodruff key from drive shaft. Place shaft end on bench and press until shaft is free, then remove shaft, rotor and vanes, cam ring, pressure plate, thrust plate and dowels. *NOTE – On models with integral air compressor, the drive shaft is not an integral part of power steering pump. To remove pump rotary group (on models with air compressor), insert a ½" brass rod through shaft seal opening in housing, then invert housing and press on end of brass rod until rotary group free, then remove components.* Remove flow control retaining plug snap ring and remove plug. *NOTE – Depress plug to remove ring.* Remove flow control valve and spring. *CAUTION* – Do not attempt to disassemble flow control valve as this is serviced as a complete assembly. Remove and discard all "O" ring seals. Remove shaft seal only if defective by prying out with a screwdriver.

REASSEMBLY: Clean all parts in cleaning solvent. *NOTE – Do not immerse shaft seal in solvent.* Before installing parts, lubricate with automatic transmission fluid. If drive shaft seal previously removed, install seal with metal backing up, using Installer J–7017 (Pontiac without integral compressor & Buick); J–7728 (Cadillac without integral compressor); J–7132–2 (Oldsmobile); J–7111 (Cadillac & Pontiac with integral compressor). Insert drive shaft into housing (models with integral air compressor), using Pump Shaft Seal Protector J–7586, and make sure shaft is properly seated. Install dowel pins in pump housing, then install thrust plate on dowel pins with ported face to rear of pump housing. Install cam ring on dowel pins with direction of rotation arrow to rear of pump housing. *NOTE – Arrow on outer edge of cam ring should be up and in direction of pump rotation.* Install rotor over splined end of pump drive shaft with countersunk side toward shaft. Make sure rotor is free on shaft splines. To install pump rotor on models with integral air compressor, place rotor in position in cam ring with countersunk side toward front of pump. On all models, install vanes in slots in rotor with radius edges toward outside of rotor so they will ride against cam ring. Use a new "O" ring seal and install pressure plate on dowel pins with ported face toward cam ring. Make sure that pressure plate is properly seated by tapping lightly around outer circumference with a brass rod. Install pressure plate springs on dowel pins. Use a new "O" ring seal and position end plate in pump housing. Install end plate installer, Tool J–7663, over end plate to depress plate below retaining ring groove in pump housing. Install end plate retaining ring making sure that ring is completely seated in groove of housing. Install flow control spring, control valve (hex screw into bore first), then install retaining plug using a new "O" ring seal, and install snap ring. Install a new "O" ring seal on pump housing, then install reservoir, stud, seal, union seal and union. *NOTE – On models with integral air compr ssor, do not install reservoir until after pump is installed on compr ssor.* On models without integral air compressor, install woodruff key on drive shaft (support opposite side of shaft when installing key).

INSTALLATION: Reverse removal procedures, then fill unit with proper fluid and adjust belt tension. Bleed steering gear by running engine at fast idle for a few minutes and turning wheels from right to left (without hitting stops). Check fluid and refill as necessary.



THOMPSON SLEEVE TYPE

DESCRIPTION: Sleeve type rotary reciprocating pump having nine cylinders operating in two cylinder blocks, one of which is diagonally offset in the pump body.

REMOVAL: Remove inlet and discharge hoses at pump and cap all openings to prevent entry of dirt or foreign matter. Loosen drive belt adjusting screw on pump bracket and remove belts. Remove pump from bracket.

DISASSEMBLY: Clean exterior of pump housing, then mount pump in a vise. Remove capscrew and reservoir and loosen the four capscrews at inlet end cap. Remove flow valve spring retainer *(CAUTION* - Flow and plunger springs are under pressure and caution should be used when removing cap and retainer to prevent spring and fitting from flying out). Remove flow valve and spring. Remove and disassemble both end caps from inlet cap body and pump housing. *(NOTE* - Plunger spring will tend to push cylinder blocks out of body, Use care when disassembling). Remove cylinder drive blocks and nine sleeves from body, as well as cylinder plunger spring. Remove ball bearing retainer ring from housing, using snap ring pliers, then remove shaft and bearing assembly. *(CAUTION - Bearing is pre-lubricated and must not be washed with solvent).* Inspect shaft for wear and ball bearing for roughness or noisy operation. If bearing must be replaced, remove shaft key and press bearing from shaft (away from splined or serrated end of shaft). Check retaining ring groove in housing. Replace bearing by supporting it on inner race, then press shaft through bearing until retainer ring stops against inner bearing race. *(NOTE* - The retaining ring must always be located between bearing and splined end of pump shaft).

INSPECTION: Check fit of sleeves in cylinder block bores and make sure they slide freely. If cylinder block is heavily scored, it must be replaced. Hairline markings on sleeves are normal. Check flow valve spool and valve liner. Slight hairline scratches are permissable, Burrs or heavy scratches can be removed with a smooth stone. *(CAUTION - Do not break the sharp edges of spool or liner).* Insert flow valve in valve body and move spool back and forth, rotating slightly on each pass. The spool must slide freely in all positions. If spool sticks or drags, check for dirt, nicks, and burrs. Remove nicks or burrs with a smooth stone. Check shaft seal in bearing cap and replace if worn or damaged. If necessary to replace, align seal properly, then press it in until shoulder stops against cap casting, using an arbor press. Check pressure relief valve *(NOTE* - Valve must not leak at any pressure below 750 lbs. and must open completely at 900 lbs.) Evidence of leakage will be seen at small holes in side of flow spool. If valve leaks, disassemble check valve seat for nicks or dirt. Replace valve seat if nicked or damaged. *(NOTE* - If valve pressure is too low, a 1/32" washer may be placed between spring and ball retainer. If too high, place the washer between valve seat and flow valve spool body). Check pump body for wear or damage. Scratches or burrs can be removed with fine emery cloth. If body is scored or damaged, a new pump should be used.

THOMPSON SLEEVE TYPE HYDRAULIC PUMP

REASSEMBLY: Clean all parts thoroughly. Press drive shaft and bearing assembly into housing and check rotation of shaft to make sure shaft turns freely. Place cylinder driven block (without splines) on fixture C-3602 and insert plunger spring, plunger and seven sleeves into driven block. Place pump body, square end down, over cylinder drive block and fixture locating pins. Use a probe to align sleeves to a uniform spacing, then install the other two sleeves. Position cylinder drive (with splines) over the sleeves. Sighting thru bores in drive block for alignment, lower the cylinder drive block until it engages the two sleeves in forward position. Use a probe and align sleeves in the 5 and 7 o'clock positions at the same time guiding cylinder block downward. Continue this procedure with the other sleeve positions until all sleeves are aligned and engaged. Push block all the way in. *(CAUTION* - Do not force block into position). Remove body and cylinder block assembly from fixture, using care to see that blocks are not forced out of body by plunger spring. Assemble a new end cap gasket on pump body, then install end cap and tighten screws finger tight. Insert a new "0" ring seal in counterbore at flow valve liner in body. Install a new pump body-to-housing gasket and install housing. *(NOTE* - It may be necessary to apply hand pressure on housing to get drive block down into body after housing is seated). Tighten the five capscrews finger tight, then check pump shaft to make sure it is freely rotating. Tighten capscrews to 25 ft. lbs. and recheck pump shaft for free rotation. Mount pump in a vise and install flow valve spool with the 3/16" land down. Place flow valve spring on top of flow spool. Replace "0" ring seal on flow spring retainer, then compress flow spring with fitting and screw fitting into place. Tighten to 20 ft. lbs. Install and align a new reservoir "0" ring seal on housing, then align reservoir so that indentation on back will mate with angular boss on suction end cap. *(NOTE* - Sighting through 9/32" hole in back of reservoir will aid in alignment). Replace copper gasket under head of reservoir capscrew, replace screw and tighten to 15 ft. lbs. *(CAUTION* - Do not attempt to align reservoir in place with the capscrew). Install shaft key, pulley and tighten pulley bolt to 20 ft. lbs. Refill pump with Automatic Transmission Fluid Type "A".

VICKERS VANE TYPE (3 PIECE HOUSING)

►*OIL PUMP CAUTION: Always cap or plug all pump ports whenever oil lines disconnected and use extreme care to keep dirt out of pump and to keep all pump parts clean*

DESCRIPTION: Constant flow vane type pump with an integral flow control valve and a separate cam (or rotor) ring housing. 1957 & later pumps have pressure plate of a slightly different design and a new "flow plate".

►*OVERHAUL NOTE:* The "flow plate" used in 1957 and later pumps is installed in pump cover assembly with the recess for pressure plate spring facing outward. Pressure plate must be installed with the spring recess facing the pump cover assembly.

VICKERS OIL PUMP: Disassembly. Thoroughly clean exterior of pump before removing plugs or disassembling parts. Then proceed as follows:

1) Remove reservoir cover and gasket, then drain reservoir. Remove four reservoir-to-pump mounting screws, then remove reservoir, gaskets, and spacers. Remove pump cover-to-body attaching bolts, then cover assembly with control valve assembly and spring. Discard cover "O" ring seal.

2) Remove pressure and return line unions with "O" rings from pump cover, discard "O" rings. Push spring retainer plug (between pressure and return line unions in cover) inward to remove. Discard "O" ring seal, remove plug snap ring. ***NOTE—It is not necessary to remove plug, "O" ring and snap ring to service remainder of pump. Remove only if evidence of leakage at this point.***

3) To disassemble control valve assembly, remove end screws with spacers, relief ball, relief spring guide and relief spring.

4) Lift pressure plate off dowel pins which extend through pump ring, remove pump ring from dowel pins in body. Remove rotor with vanes from body, discard "O" ring from groove in pump body. Remove bearing retainer snap ring from front face of pump body.

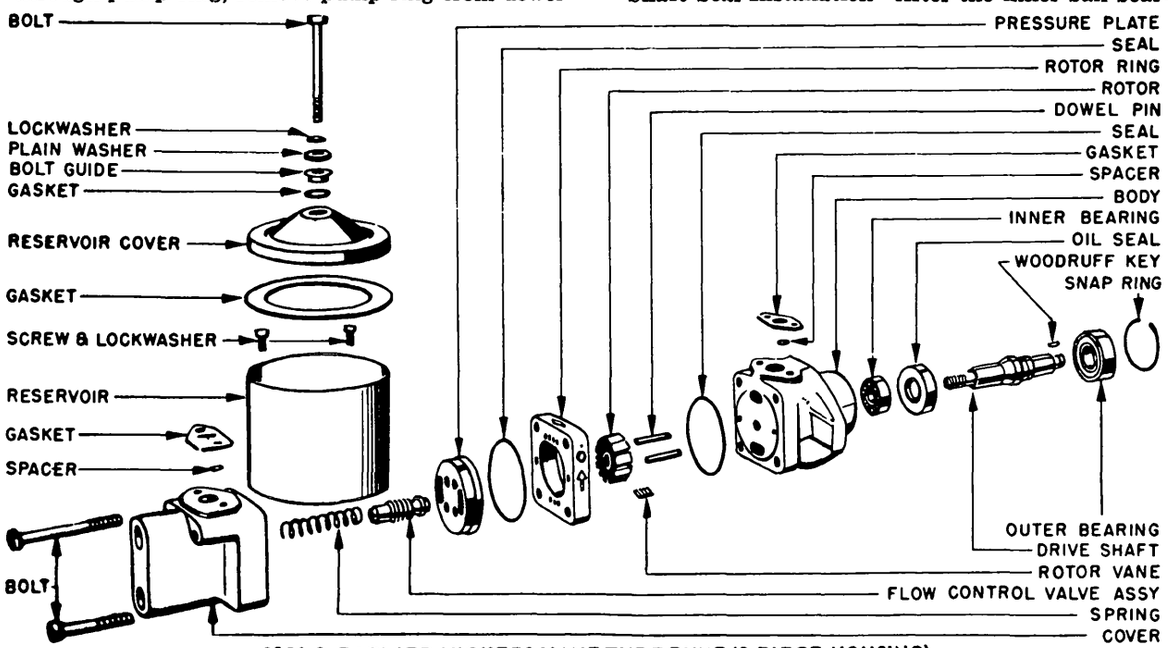
5) Remove drive shaft and outer bearing assembly from pump body, press outer bearing off drive shaft over threaded end of shaft, after removing woodruff key from shaft.

6) Using punch, tap drive shaft seal and inner bearing from pump body (*CAUTION*—Seal must be removed first to permit removal of bearing).

Cleaning & Inspection: *CAUTION*—Do not wash large sealed bearing in cleaning solvent which may wash lubricant out of bearing (wipe bearing and shaft assembly with clean cloth only). Clean all other parts with clean kerosene or solvent, wipe dry with clean lint-free cloths. Inspect both bearings for wear or roughness, inspect shaft for wear. Check fit of pump vanes in rotor slots (vanes should be snug but must slide freely in slots), replace rotor if vanes excessively loose, replace vanes if worn or scored. Inspect all ground surfaces of cam ring for roughness or wear (slight irregularities can be stoned out), replace ring if inner cam surface scored or worn. Inspect flat surfaces of pressure plate and body for wear or scoring (faces may be trued up by lapping until smooth and flat) *CAUTION*—all traces of lapping compound must be cleaned out. Inspect relief valve poppet and flow control valve plunger for wear or scoring paying particular attention to seating surfaces. Clean out all passages in pump cover and body.

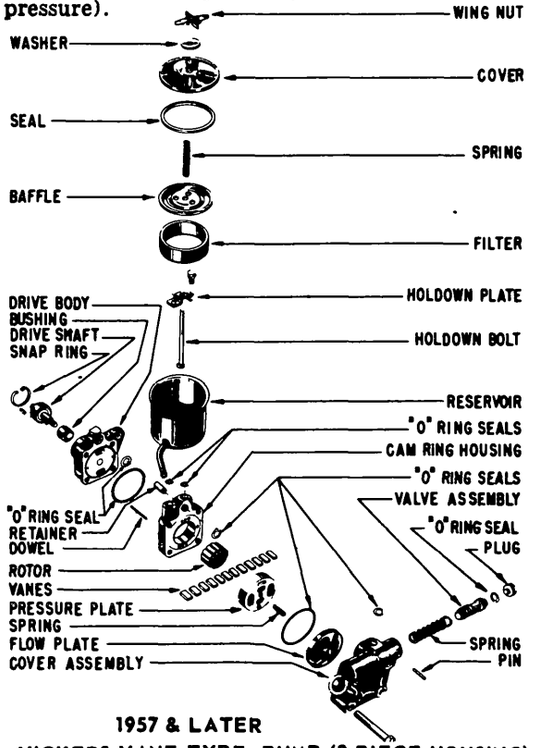
Reassembly: Use all NEW seals and gaskets. Lubricate all moving parts with clean engine oil and install parts in reverse order of disassembly procedure (above) with particular attention to the following points:

Shaft Seal Installation—After the inner ball bearing is installed in pump body, install seal with the two 1/16" holes in casing toward outside and use a tube or shaft 1 3/4" in diameter to apply pressure on outer edge of seal to seat it in body.



Bearing Installation—Large sealed bearing should be installed with stamped face of inner race toward threaded end of shaft, small bearing with stamped face of inner race toward splined end of shaft. Press on inner race only when installing bearings.

Cam Ring Installation Caution—Install ring with marks made during disassembly lined up and make certain that **arrows on ring point in direction of pump rotation** (clockwise viewed from front or shaft end of pump).



Rotor & Vane Installation—Install vanes with rounded (radius edge) outward toward cam ring.

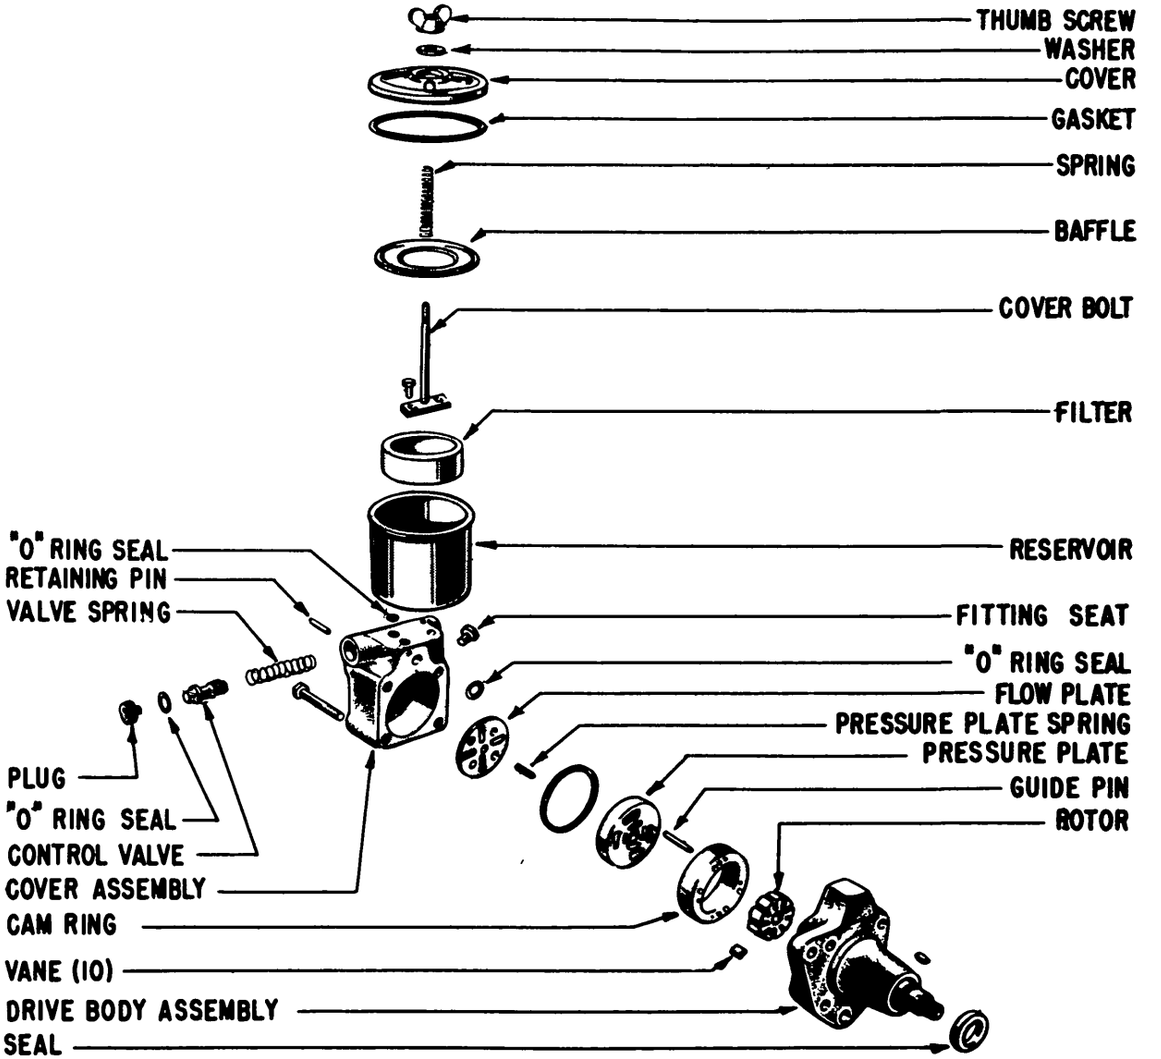
Relief Valve Assembly Installation—Make certain that **all of the original shim washers** are re-installed in the valve plug (these shims control oil pressure). If any of the relief valve parts are replaced, valve operation must be tested and adjusted after pump installed on car as follows:

Relief Valve Testing & Adjustment—Use Gauge J-5176 to check pump pressure. See Testing Hydraulic Oil Pressure (above). Relief valve should start to open (will be indicated by slight buzzing noise in pump) at pressure of 700 lbs. or slightly higher and maximum pump pressure should not exceed 900 lbs. with engine speed increased above idle. If pressure not correct, adjust number of shims in relief valve plug for correct performance (add shims to increase pressure, remove shims to lower pressure).

1956 & EARLIER VICKERS VANE TYPE PUMP (3 PIECE HOUSING)

1957 & LATER VICKERS VANE TYPE PUMP (3 PIECE HOUSING)

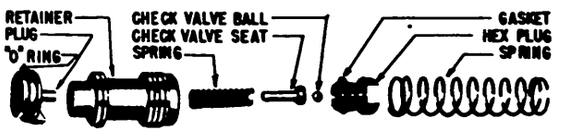
VICKERS VANE TYPE (2 PIECE HOUSING)



►*1957 DESOTO (EARLY) NOTE:* A "Three Housing" Vickers Vane type pump is used on these models. *See "Vick rs Thre H using Vane Type Pump."*

DESCRIPTION: This new pump consists of a two-piece housing (drive body & cover assembly). A new rotor cam ring is retained on pump drive body with two guide pins replacing the separate cam body on previous vane type pumps.

REMOVAL: Loosen pump drive belt adjusting screw and remove belt (or belts). Disconnect intake and discharge hoses and cap the openings. Remove pump from engine.



DISASSEMBLY: Drain pump and remove reservoir cover, baffle plate and filter. Remove reservoir retaining screws and remove reservoir and three "0" ring seals, Remove pump pulley, then remove screws attaching pump cover to drive body assembly and lift cover straight up from drive body. Drive retaining pin out of cover assembly and remove control valve assembly. *(CAUTION* - Control valve plug is spring loaded). Remove hex plug from end of control valve plunger and remove relief valve check ball, seat and spring. Remove flow plate and pressure plate spring from cover, then remove pressure plate, rotor cam ring, guide pins and rotor (with ten vanes) from drive body. Place pump body (with front end down) in end of a steel pipe which is large enough to clear forward end of drive body housing. Place drive body and pipe tool in an arbor press, and press at rear (splined) end of shaft to drive shaft, retainers, front bushing and seal out of housing. *(NOTE* - Some early pumps had a bronze retainer ring on shaft that may break when pressed out. If this happens, continue driving shaft completely out and then pry seal out with a screwdriver. Install new steel retaining rings at reassembly). Remove front bushing from body. *(CAUTION - D n t r m v rear bushing. If bushing is damag d, replac compl t drive body housing).* Check all parts for wear or damage and replace as necessary.

REASSEMBLY: Install new steel retainers around shoulder on pump shaft. Guide splined end of shaft through rear bushing and seat shaft and thrust washers against drive body casting. Slide a new front bushing over drive shaft and down against body casting. Be sure tapered end of bushing enters drive body evenly. Using a suitable tool (DeSoto C-3604) and an arbor press, press bushing into body until it seats against retainers. Be sure tool is in alignment with bushing to prevent damage to drive shaft shoulder. Coat a new seal with Lubriplate and install it over shaft and into position on drive body with lip of seal in and numbered side out. Drive seal into place using a suitable tool (DeSoto C-3603). Place drive body assembly in a vise and install rotor with ten vanes on splined end of shaft. *(NOTE - Vanes should be positi ned in rotor with rounded nd ut).* Insert guide pins in drive body and seat cam ring over pins. *(CAUTION - Cam ring must be installed so that arrow on outside of ring points in a counterclockwise direction when viewing rotor end of shaft).* Slide pressure plate over pins against cam ring with spring recess hole up. Position flow plate at bottom of cover body with spring recess side out. Install new "0" rings in drive body and insert pressure plate spring in center recess hole in plate. Position cover body on drive body and install bracket and attaching screws and tighten to 25 ft. lbs. Install relief valve spring in control valve plunger, then install check ball seat and ball. Hold in place and install hex plug and gasket. Install control valve spring in cover assembly and install control valve plunger, plug (with new "0" ring seal), and then drive in the retaining pin. Install three "0" ring seals on cover body and install reservoir, filter, baffle plate, and reservoir cover. *(NOTE* - Install cover washer under thumb screw, with the groove upward).

VICKERS VANE TYPE HYDRAULIC PUMP (2 PIECE HOUSING)

INSTALLATION: Reverse removal procedure and tighten pump belt.

VICKERS CONTR L VALVE ASSY.

GEMMER WORM & ROLLER (1955 & EARLIER)

Chrysler, DeSoto, Dodge (1954-55)
Ford Pass. Cars & Trucks (1954-55)
Hudson (1954-55)
Lincoln (1954-55)
Mercury (1954-55)
Nash (1954-55)
Packard (1954-55)
Plymouth (1954-55)
Rambler (1954-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 FORD STEERING LINKAGE ALIGNMENT CAUTION (Victoria & Sunliner):* An 11/32" spacer is used between steering column bracket and instrument panel. If spacer omitted, binding or hard steering condition may result, due to misalignment.

►*1955 FORD PASS. CAR & COURIER STEERING WHEEL ATTACHING NUT INSTALLATION CAUTION:* Nut should be torqued to 40-60 ft. lbs. and staked once with prick punch to prevent nut from loosening.

►*1955 FORD PASS. CAR SECTOR SHAFT BEARING PRODUCTION CHANGE:* Since approximately June 27, 1955 a spacer (AD-3567-A) has been used in production to assure correct positioning of sector shaft bearings and should be installed on earlier production units whenever it becomes necessary to replace the bearings. Install spacer between the two bearings on the sector shaft Bearings should be installed with Tool T52L-3576-AAD.

►*1955 FORD F-100, 250 TRUCK DRAG LINK INSTALLATION CAUTION:* It is possible to install drag link in reversed position. When properly installed, offset end of drag link is attached to sector shaft arm, and the lubrication fittings will be on the bottom side of the link.

►*1954 RAMBLER INTERMITTENT OR LACK OF HORN OPERATION CORRECTION:* May be due to poor ground circuit between horn button retaining contact plate and chassis, through steering worm tube. To correct, remove horn button cap and spring. Strip 2" of No. 14 wire of insulation and twist strands together. Loosen one of Phillips head screws which hold lower spring retainer to wheel hub. Loop one end of bared wire under Phillips head screw and tighten it in place. Loosen steering wheel nut and loop other end of bared wire beneath it. Tighten steering wheel nut securely.

DESCRIPTION: Consists of "hour glass" type worm mounted on steering shaft and carried on roller bearings at top and bottom. Chrysler & DeSoto models are of "straddle" design with added bushing at adjusting screw end of shaft within side cover.

ADJUSTMENT: Before making adjustments, align steering gear as follows: Loosen gear-to-frame bracket bolts (on some models, also loosen dash bracket bolts). Allow gear to align itself, then tighten gear-to-frame bolts. If necessary, shim dash bracket, or elongate mounting holes so column will not be sprung when bracket bolts are tightened.

Worm Bearing Adjustment (In Car): Chrysler, DeSoto, Dodge, Plymouth—If excessive endplay exists, remove steering gear pitman arms, drain housing, and disconnect horn wire at connector between steering gear and horn. Remove capscrews holding grease retainer cover at bottom of housing. Remove shims of sufficient thickness to eliminate endplay in worm, but not enough to cause binding when cover is bolted tightly in place. Turn steering wheel from extreme right to left. If any stiffness exists, too many shims have been removed.

Ford (Pass.), Lincoln & Mercury—Disconnect sector shaft from steering arm to idler arm rod. Turn steering wheel two complete turns from straight ahead position (spokes in a horizontal position) with steering gear arm pointing directly forward). Hook a spring scale to steering wheel spoke at wheel rim and rotate wheel at least one complete turn, noting the pull required to keep wheel moving which should be 1/8 to 5/8 lb. If necessary to adjust, add or remove shims as follows: Remove screws securing steering gear housing upper cap to housing and work cap and column jacket upward to allow clearance (if additional working clearance required, remove steering wheel). To add a shim, split shim at one point, then install the shim with the split in the upward position (make sure that split ends do not overlap. To remove shims, separate shims from shim pack with a knife blade, passing knife blade all the way around shim pack being careful not to damage shim pack. Remove one shim at a time, checking bearing preload after each variation in shim pack. *NOTE*—Steering column and housing upper cap must be assembled on steering gear housing each time preload is checked.

Ford Trucks—Align steering gear assembly as indicated above. Reposition column tube if necessary so that 1/16" clearance exists between upper edge of steering column tube and shoulder of steering wheel. Disconnect pitman arm from sector shaft and loosen locknut on sector shaft adjusting screw. Turn adjusting screw counter-clockwise to remove load from worm. Turn steering wheel in one direction to limit of its travel, and using a scale, measure pull required at rim of wheel to keep the wheel rotating. The pull required should be ¼-¾ lb. (F-1, 2, 3, 100, 250, 350, ½ & ¾ Ton Trucks), ½-1 lb. (Other Trucks). Adjust preload by adding or removing shims from underneath steering gear housing end plate.

Hudson, Nash & Rambler - Turn steering wheel approximately one turn from straight ahead position and secure wheel to prevent movement. Shake front wheel sideways noting any end movement that may be felt between steering hub and jacket tube. *(CAUTION*—Be careful that movement noted is not caused by steering jacket tube bearing). Adjust endplay by loosening the four cover capscrews about 1/8". Add or remove shims as necessary *(NOTE*—Remove shims by separating with a knife being careful not to damage shim pack. Shims can be added by spliting shims and inserting in place with split toward the top).

Packard—Remove pitman arm from cross shaft. Turn steering wheel to extreme right or left and back up 1/8 turn. With spring scale attached to spoke of wheel at rim, pull required to turn wheel should not be less than ½ lb. or more than 1 lb. Add or remove shims in same manner as for Hudson, Nash, Rambler (above).

Worm & Roller Mesh Adjustment (In Car): Chrysler, DeSoto, Dodge, Plymouth—Remove pitman arm from shaft and install another arm for use during adjustments. Turn steering wheel to mid-position (high spot). Check movement of steering pitman arm back and forth to determine amount of backlash. If any backlash exists, adjust as follows: Remove roller tooth shaft adjusting screw locknut and slide lock plate off far enough to clear lock boss on roller tooth shaft cover. Tighten roller tooth shaft adjusting screw enough to eliminate freeplay between roller tooth shaft and worm, *but it must not bind.* Slide lock plate in position against roller tooth shaft cover and lock it. Install and tighten adjustment screw locknut, Check steering gear operation and adjust if necessary.

Ford Pass. Car, Ford Truck, Lincoln & Mercury—On Passenger Cars, disconnect sector shaft arm from steering arm to idler arm rod. On Truck Models, disconnect steering sector arm (pitman arm) from the sector shaft. Attach a spring scale to steering wheel rim and pull the wheel through the "high spot" (straight ahead position), and note reading on scale.

Ford Pass. Cars—Reading should be at least ½ lb. above worm bearing preload, but total reading must not exceed 1 5/8 lbs. To adjust, remove adjusting screw cover and locknut. Rotate adjusting screw clockwise while moving steering gear arm back and forth until all backlash has been removed.

Ford Trucks—Reading should be 1-2 lbs. (F-1, 2, 3, 100, 250, 350, 1/2 & 3/4 Ton) 1 1/2-2 1/2 lbs. (Others). To adjust, remove adjusting screw cover and locknut. Center steering wheel, turn adjusting screw in a clockwise direction until all endplay is removed from sector shaft.

Lincoln & Mercury—Reading should be 1-1 5/8 lbs. To adjust, turn sector shaft adjusting screw in if reading is less than 1 lb., loosen screw if reading is greater than 1 5/8 lb.

Hudson, Nash & Rambler - With pitman arm disconnected from shaft, place steering wheel in center position ("high spot"). If steering wheel removed, the wide flute on upper end of worm tube should be centered at the bottom. Shake pitman arm sideways to determine amount of clearance between worm and cross shaft roller. A movement in excess of 1/32" indicates adjustment required. Remove locking cap from external adjusting screw and remove star washer. Tighten the external screw, **but do not overtight n,** until sideplay is less than 1/32". Install star washer and locking cap.

Packard—With pitman arm removed from cross shaft and steering wheel in straight ahead position (on "high spot"), attach scale to rim of steering wheel and note pull required to move steering wheel through the "high spot". The pull should be ¾ lb., greater than that of worm bearing preload (see above), but not more than 2 lbs. To adjust, place steering wheel on the "high spot" and remove cross shaft adjusting screw locknut. Raise lockplate enough to clear jaws on cross shaft cover and turn adjusting screw until effort re-

CONTINUED ON NEXT PAGE

GEMMER WORM & ROLLER (C ntinued)

quired to pull steering wheel through "high spot" is 1½ to 2 lbs. Install locknut and tighten.

STEERING WHEEL POSITION: With steering at mid-point (roller on high point of worm), intermediate steering arm (when used) should be on center line of car, wheels should point straight ahead, and steering wheel position should be correct as noted below. Check steering wheel position as follows:

Chrysler, D S t , D dg , Plymouth: Steering wheel hub, gear arm, tube, and gear roller shaft are machined with master serrations to place wheels straight-ahead when steering wheel is in its center position. No attempt should be made to change relative position of these parts by altering master serrations. Improper positioning of steering wheel should be corrected only by adjusting tie rods.

Ford Pass. Cars: When steering wheel is on the high point, the front wheels should be in a straight ahead position, spokes of steering wheel horizontal and steering gear arm pointing directly forward. Check steering wheel spoke position while driving car straight ahead. If spokes not in horizontal position, adjust as follows: Set steering wheel spoke in horizontal position. Scratch a mark on each steering arm connecting rod sleeve and the spindle connecting rod tube, then loosen sleeve clamp bolts. If left-hand steering wheel spoke was below horizontal when checked, turn both connecting rod sleeves downward the same amount. One complete turn of sleeve equals approximately one inch of steering wheel rim travel. Turn connecting rod sleeves upward if left-hand wheel spoke was above horizontal. Tighten sleeve clamp bolts to 12-15 ft. lbs. torque.

Ford Trucks: Place front wheels in straight-ahead position, place steering wheel on steering shaft with single spoke facing straight down. Using a wood block, tap steering wheel in center of hub until firmly seated on steering shaft.

Hudson 6 & 8 (1954) - Notch in end of shaft should point straight down (visible with horn button and contact plate removed) and steering wheel spokes should be horizontal with roller on "high" point of worm. To adjust, shift shims from one ball seat to other in steering arm end of drag link.

Huds n (1955), Nash, Rambler: Steering wheel marked on underside of hub. Install steering wheel with this mark straight down and in line with wide serration on upper end of steering gear tube. In this position, steering gear roller should be on "high" mid-point of worm and front wheels should point straight ahead.

Lincoln & M rcury: To align steering wheel disconnect connecting link at steering gear arm, locate steering wheel in center position (turn wheel back ½ full travel from either end position) with steering gear roller on "high" mid-point of worm and wheel spokes horizontal, set front wheel in straight-ahead position. Adjust both tie rods equally until connecting link can be reconnected to steering gear arm without disturbing position of steering wheel and front wheels.

►*CAUTION:* Both tie rods must be adjusted equally (turn both adjusters equally in opposite direction) to avoid disturbing original toe-in setting. Recheck toe-in after adjustments have been made.

Packard: Place steering wheel in straight-ahead position and center steering gear on high spot. Adjust steering cross tube sleeves until wheels are in the straight-ahead position.

STEERING WHEEL & HORN RING OR BUTTON REMOVAL

►*INSTALLATION NOTE—Where installation instructions are omitted (below); reverse removal procedure. Special instructions are not required.*

Chrysler & DeSoto (1954-55) Except Hydraguide:

Horn Ring Removal—Disconnect battery and center steering wheel in straight ahead position. Press down on horn ring ornament and turn counter-clockwise. Lift out ornament retaining spring and pad. Disconnect horn wire from terminal on travel plate and insulator assembly. Remove bushing, travel plate, horn blowing contact ring spring and triangular ground plate. Curl and push wire into steering tube to make room for steering wheel puller pilot.

Steering Wheel Removal - Remove steering wheel with Puller C-612 (1954), C-3428 (1955).

Dodge (1954):

Horn Ring Removal—Disconnect horn wire at connector near bottom of steering column, push down on horn blowing ring medallion, turn clockwise and remove medallion, retainer spring and cushion Loosen and remove the three horn ring retainer screws and spacer bushings, then lift out horn ring, travel plate and insulator assembly, wire, contact spring plate and ground plate

Horn Button Removal (Some 6 Cyl. Models)—Disconnect horn wire at connector near bottom of steering column, turn horn button medallion retainer ⅛ turn counter-clockwise, lift off horn button, horn button retainer, contact spring and plate. Pull out horn wire and spacer bushing from center of steering tube. After removing steering wheel nut, lift out horn button contact cup, remove screw holding horn button retainer fastening plate and base to steering wheel

Installation—Be sure contact spring plate, on models with horn blowing ring, is installed with colored dot appearing on top side On all models, align master serration on steering tube with serration on steering wheel hub before installing.

Dodge, 1955 All Models:

Horn Ring Removal—Disconnect battery and center wheel in straight-ahead position Remove two screws from underside of the medallion and remove medallion. Disconnect horn wire from terminal on travel plate and insulator and remove horn ring, travel plate, and insulator assembly, contact spring and ground plate Push horn wire down into steering tube

Steering Wheel Removal (All Dodge Models)—Remove wheel nut and washer. Attach wheel puller Tool C-612 by means of the threaded holes in steering wheel hub and remove wheel *NOTE*—When installing steering wheel be sure that master serrations are in line and the direction signal cancelling cam on bottom of wheel is inserted between switch levers

F rd Pass. Cars (1954-55):

Horn Ring or Button Removal—Disconnect horn wire from connector at bottom of steering gear housing Remove horn button or ring by pressing down and turning counter-clockwise Lift spring from steering wheel hub Pull horn wire and contact assembly out of steering shaft.

Steering Wheel Removal—Remove steering wheel nut and remove wheel with Puller 3590-N

Installation—Align master splines, tighten nut to 50-60 ft lbs

Ford Trucks (1954-55): See Pass. Car instructions and note the following:

Steering Wheel Installation (Trucks)—Place front wheels in straight-ahead position, place steering wheel on shaft with single spoke facing down. Using wood block, tap steering wheel in center of hub until firmly seated Stake end of shaft to nut at one point

Hudson (1954):

Horn Button Removal—Push down on button and rotate to release from retainer. Pull wire up slightly and push wire sleeve into large opening of contactor. Lift out contact cup and remove horn wire.

Horn Ring Removal—Disconnect horn wire at horn relay. Pry ornament and ring assembly out of steering wheel spoke cover. Remove three screws attaching horn ring insulator to horn ring. Remove insulator ring, contact cup and wire.

Steering Wheel Removal—Place adapter Tool J-739-10 around jacket tube with small diameter of adapter under steering wheel hub. Position foot of puller J-739-B around outside diameter of adapter. With steering wheel nut partially threaded on the column tube, run puller screw down tight against the wheel nut to release steering wheel.

Steering Wheel Installation—Install wheel on shaft with two spokes horizontal and notch in steering shaft pointing straight down. On wheels with three spokes, third spoke should point down. Torque nut to 20-30 ft. lbs.

Hudson (1955): Same as for 1954-55 Nash & Rambler.

Lincoln (1954-55):

Horn Ring Removal—Remove cap and emblem assembly by grasping with the hand and pulling outward from steering wheel hub. Remove three screws holding horn ring securing plate to steering wheel. Remove horn ring securing plate, gasket and spring.

Steering Wheel Removal—Remove steering shaft nut. Install Tool 3600-D and remove steering wheel.

Mercury (1954-55):

Horn Ring Removal—Remove cap and emblem assembly from steering column head by rotating cap counterclockwise with palm of the hand. Remove three screws holding horn ring retainer plate to steering wheel. Remove horn ring, retaining plate and spring.

Installation Note—When installing horn ring spring, be sure that spring ends are properly seated in spring stops.

Steering Wheel Removal—See Lincoln, above.

Nash & Rambler (1954-55):

Horn Ring Removal—Rotate steering wheel medallion counter-clockwise to remove. Remove horn contact plate and insulators. Remove wheel (see

CONTINUED ON NEXT PAGE

GEMMER WORM & ROLLER (Con.inued)

below). Remove horn ring after wheel removed.
Steering Wheel Removal—Remove steering wheel nut and install steering wheel puller Tool J-2982.

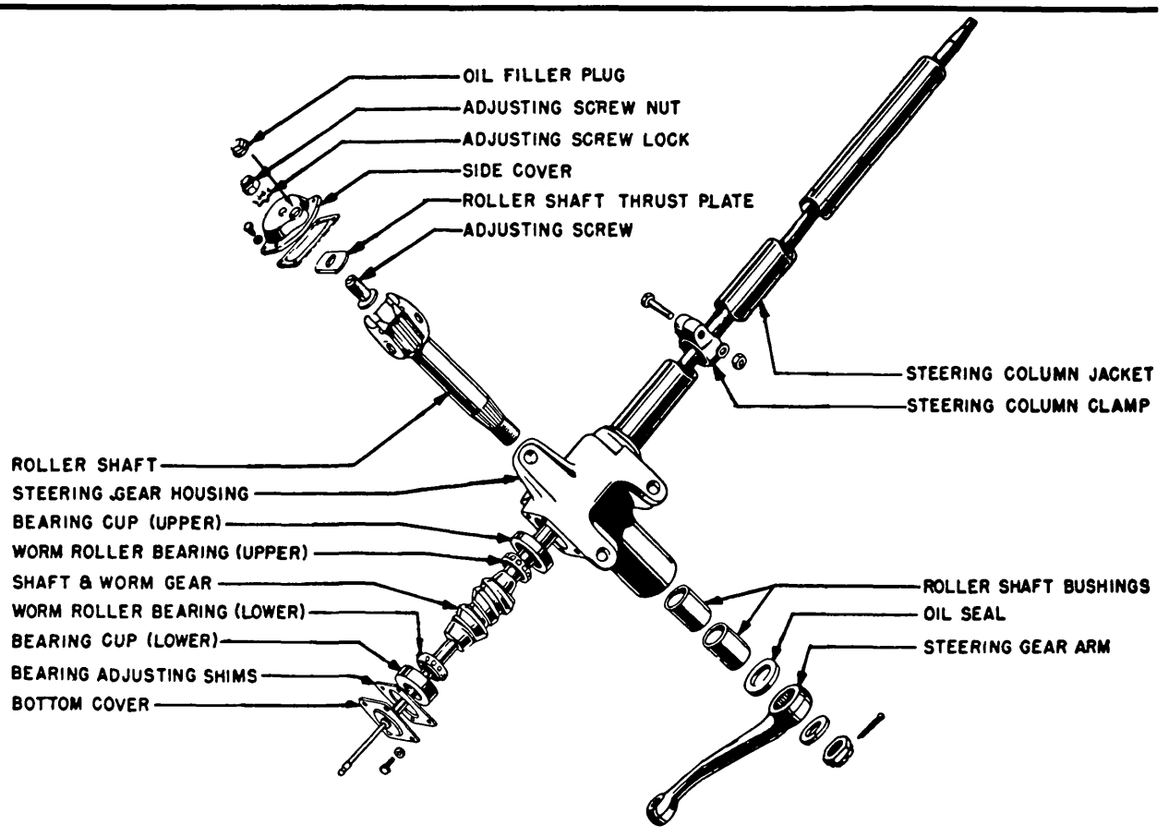
Packard (1954-55):

Horn Ring Removal—Depress medallion slightly, rotate counter-clockwise until it pops up (do not pry up). Remove horn ring assembly and contact plates.

Steering Wheel Removal—Remove steering wheel nut and install steering wheel puller Tool J-2557 and remove wheel.

Plymouth (1954-55):

Horn Button or Horn Ring Removal—On models with a horn button, remove screws from underside of wheel and remove horn button retainer. Lift out button, spring base assembly. Contact cup can be removed after steering wheel removed. On models with horn ring assembly, two types are used. With the "one-piece" type, depress the ornament carefully and rotate it counter-clockwise. Remove ornament, spring and rubber grommet. Remove the three retainer screws and lift off ring. With the "two-piece" type, the ornament is held with four clips in hub cover. Pry hub cover upwards and remove the three retainer screws. Remove horn ring retainer and horn ring.
Steering Wheel Removal—Remove nut and install puller C-612 and pull wheel from steering tube.



STEERING GEAR REMOVAL & INSTALLATION

►*INSTALLATION NOTE: Installation procedures are the reverse of those for removal.*

Chrysler & DeSoto (1954): Removal - Remove shroud from bottom of steering column jacket and handbrake, then remove parts as necessary to fold floor mat back out of way. Remove floor board and accelerator pedal and rod assembly. Disconnect rod from transmission cross-over lever, horn wire, and turn signal wires. Disconnect transmission rod from shaft lever control arm, then remove two top steering gear-to-frame bolts. Remove starting motor, steering arm, and drag link. Disconnect brake pedal from master cylinder, then remove lower steering gear-to-frame bolt (reach through from front compartment). Remove dash-to-steering column instrument panel stud nuts and remove steering gear assembly.

Chrysler & DeSoto, 1955: Removal—*(NOTE*—It is not necessary to remove the complete steering column and mast assembly from the car for servicing gear chuck and worm shaft). Remove steering wheel (see above). Loosen jacket bracket bolts at instrument panel. Remove dust pad retaining screws. Raise front of car and remove steering gear (pitman) arm from gear shaft. Loosen jacket-to-gear chuck clamp bolt. Remove gear chuck-to-frame attaching bolts and work gear chuck and shaft assembly out of jacket. Remove assembly from lower side of car.

Dodge (1954): Remove left front wheel, then remove steering wheel, front seat cushions, floor mat and pedal opening cover. Disconnect direction signal wires under instrument panel and remove transmission controls from steering column. Remove bolts holding steering gear to frame, then remove pitman arm. Remove steering gear post bracket cap at instrument panel and remove steering gear assembly from top side of car by lifting up as far as possible, and then withdrawing from right hand side of car.

GEMMER MODEL 305 & 335 STEERING GEAR

Dodge (1955): Same as for 1954 models except that steering gear is removed from below car. If steering column is to be removed, it must be removed from top side of car.

Ford Pass. Cars (1954-55), Except Thunderbird: Removal - Remove steering wheel, then disconnect steering column from instrument panel and gearshift lever from rods. Remove bracket securing gearshift tube to steering column tube, then remove gearshift tube pin and gearshift levers. Loosen steering column clamp and pull tube assembly off shaft. Disconnect drag link from pitman arm and remove pitman arm. Remove steering gear attaching bolts and remove gear.

Ford Thunderbird (1955): Removal—Disconnect wires at bottom of steering gear housing. Loosen the lower steering column clamp and remove the two screws from upper steering column bracket. Remove horn ring from steering wheel, and remove upper steering column, upper steering shaft, and steering wheel as an assembly from the car. Raise front of car and remove steering sector shaft arm from sector shaft, then remove bolts holding steering gear housing on frame side member. Remove lower steering gear assembly from car.

Ford Trucks (1954): Removal - Remove steering wheel, column and brake pedal plate, and steering gear pitman arm. Remove steering gear-to-frame attaching bolts and the clamp holding steering gear column tube to instrument panel. Remove steering gear from underneath truck. *NOTE - It may be nec ssary to raise front of truck.*

Hudson (1954): Removal - Remove left front wheel and fender shield, then remove left frame-to-cowl brace. Remove steering wheel, horn wire, bearing spring and and spacer, gearshift lever tube, and steering gear jacket tube. Remove steering gear-to-frame bolts and disconnect drag link from pitman arm. Slide gear forward and rotate until pitman arm is clear, then remove gear through opening in fender.

Hudson (1955): See 1955 Nash Ambassador & Statesman.

Lincoln & Mercury (1954-55): Removal—On models with Power Brakes, remove clamps that secure reservoir hose to fitting on brake booster cylinder and to the dash panel. Move the hose away from the steering column opening in the dash panel. On Lincoln, remove front seat cushion from vehicle and cover seat back to protect upholstery. On Mer-

C NTINUED N NEXT PAGE

GEMMER WORM & ROLLER

(C ntinu d)

cury, move front seat to extreme rear position and cover seat and seat back to protect upholstery On all cars, remove steering wheel with Tool 3600-D Disconnect steering column electrical connections. Remove accelerator pedal from accelerator push rod Remove brake and clutch pedals. Pull floor covering away from dash panel opening. On Lincoln, disconnect speedometer drive cable from instrument panel and pull through lower floor pan opening cover On all cars, remove insulator and floor pan opening cover plates Remove two capscrews that secure steering column bracket to instrument panel and pedal support bracket Remove cotter pin(s) and release shift rod(s) from steering column shift arm(s). Loosen clamp on lower steering column at steering gear housing Raise column sufficiently to disconnect wires at neutral switch on Automatic Transmission equipped models only Remove steering column tube from steering shaft through inside of vehicle. Raise front of car and remove nut securing pitman arm to steering sector shaft Remove steering gear arm (pitman) from sector shaft, using Tool 3590 Loosen three bolts that secure steering gear assembly to frame side rail *(CAUTION—Remove shims, if any, located between mounting bolts and frame side rail. Mark bolt holes and number of shims required, to facilitate assembly. Mark shims for identification with bolt holes).* With helper in passenger compartment and another under vehicle, remove the three bolts that secure steering gear assembly to frame side rail, and remove unit through passenger compartment CAUTION—Mask lower portion of instrument panel for protective purposes when removing unit

Nash Ambassad r & Stat sman (1954): Removal - Remove pitman arm, then disconnect shift rods from levers and steering gear body from side rail. Remove horn ring and steering wheel and disconnect all wires attached to steering column jacket tube. Fold up floor mat, then loosen capscrews attaching pedal shafts to levers and remove pedal shafts Disconnect jacket tube from instrument panel, then loosen clamp bolt at end of jacket tube and slide steering gear assembly from jacket tube,

Nash (Ambassador & Statesman) 1955: Removal—Disconnect shift rods at shift levers and pitman arm from shaft Remove mounting bolts at steering gear housing and disconnect at the instrument panel bracket Remove steering wheel Disconnect all wires under dash that are connected to jacket tube Remove complete assembly through access opening in toeboard

Rambler (1954-55) R moval - Remove steering wheel, then disconnect pitman arm from linkage Drain cooling system and remove radiator-to-water pump hose. Loosen clamp on lower end of steering jacket tube and bolts attaching gear to frame sill Remove gear assembly from under car.

Packard (1954-55): Removal - Disconnect direction signal switch wires at connector and windshield wiper control cable at wiper motor, then remove steering wheel. Disconnect shift lever at pivot pin, then turn back floor mat and remove pedal cover plate. Disconnect shift rods at lower end of steering column, then remove gear-to-frame attaching bolts Remove pitman arm from shaft and steering column-to-instrument panel bracket cap. Lift column and shroud assembly up through opening in floor board and remove steering gear from under hood

Plymouth (1955): Removal - Remove steering wheel Loosen toe-board assembly, then remove lower half of instrument panel bracket and loosen jacket clamp. Disconnect pitman arm and remove housing bolts at frame. Hold column jacket and slide gear assembly out from below, leaving jacket and shift controls inside car

STEERING GEAR OVERHAUL

OVERHAUL (STEERING GEAR ASSEMBLY): Clean the outside surfaces of steering gear assembly thoroughly. Then mount assembly in vise, clamping the housing so both shaft and roller cover and the housing end cover are accessible

Disassembly (Shaft and Roller Assembly): Remove shaft and roller adjusting screw, locknut and lockplate, then remove bolts attaching shaft and roller cover plate to housing Turn adjusting screw clockwise to raise cover away from housing to allow adjusting screw to slide out of slotted end of shaft and roller assembly Remove cover screw and gasket and disassemble adjusting screw and thrust washer from cover Push upward on lower end of roller shaft and lift shaft and roller assembly from housing. *CAUTION—Do not try to disassemble roller from shaft as these parts are replaceable only as an assembly.*

Housing Cover Plate and Shims—Remove housing cover attaching bolts and take off cover, and shims used to adjust worm bearing *(Check total thickness of shims with a micrometer so it will be possible to use same thickness when assembling steering gear).*

Worm and Bearings—Remove lower worm bearing cup, lower bearing, and the worm and steering column assembly, and upper bearing (The lower bearing cup can be loosened by tapping lightly on end of steering shaft with hammer). Remove upper bearing cup from housing by carefully driving it out with a brass drift Remove roller shaft oil seal only if it needs replacement or if the roller shaft bushings are to be replaced

Cleaning and Inspection—Clean all lubricant from parts and housing, using a stiff brush to clean bearings and worm and roller teeth Check all parts for wear, pitting, chipping or scoring Replace parts as necessary Check fit of roller shaft in housing bushings The shaft must not be loose, but it must not bind in bushings Check shaft for roughness or wear. (See Bushing replacement below). Check condition of shaft and roller adjusting screw thread With the adjusting screw and thrust washer inserted in slotted end of roller shaft, clearance between head of screw and bottom of slot should not exceed 002" Replace adjusting screw and or thrust washer to obtain right clearance Roller on shaft must rotate freely If rotation is rough, if roller is loose or if there is endplay, shaft and roller assembly must be replaced Be sure there is no indication of twisting or distortion of roller shaft. Steering column (shaft) run-out at upper end should not be greater than 250".

Bushing Removal and Replacement—Press old bushings from housing and install new bushings, pressing them into the same position as old bushings Line ream bushings after installation to 1.125-1 1255". Check roller shaft in bushings to make sure it is free Install a new roller shaft oil seal with correct side toward outside of housing.

Reassembly (Worm and Bearings): Install upper worm bearing cup, driving it carefully into counterbore in housing, wide face of cup toward bottom of counterbore Do not cock in counterbore and make sure it is seated fully Apply steering gear lubricant to worm bearings, bearing cups and on the worm threads before installing in housing Fit upper worm bearing into place over end of steering column shaft and onto bearing surface at end of worm Install worm and shaft into housing so that bearing fits into bearing cup Fit lower bearing onto bearing surface on ower end of worm and install the lower bearing cup in housing, with tapered part of cup toward worm bearing

Housing Cover Plate and Shims—Select shims totalling same thickness as previously used, or use old shims if in good condition (Shims 002". 005" 010" are available as service parts) Install shims and cover on housing and tighten bolts to 10-15 ft lbs torque Steering column shaft should rotate freely and smoothly without binding and without endplay (See Adjustment below)

Shaft and Roller Assembly—Lubricate roller, roller shaft, and bushings with steering gear lubricant Then install assembly in steering gear housing being careful not to damage oil seal when passing shaft through seal Turn steering column shaft to mesh teeth of roller at center of worm Assemble thrust washer on roller shaft adjusting screw and turn screw into roller shaft cover Install this assembly and cover gasket on steering gear housing, fit head of adjusting screw and thrust washer into slot in roller shaft Turn screw counter-clockwise to seat cover against housing Install cover bolts and tighten securely

STEERING LINKAGE: *See "Steering Linkage"*

1956-59 GEMMER WORM & ROLLER

Chrysler (1956-59)
DeSoto (1956-59)
Dodge (1956-59)

Hudson (1956-57) ①
Mercury (Early 1956) ①
Nash (1956-57) ①
Packard (1956) ①
Plymouth (1956-59)
Rambler, Exc. American (1956-57) ①
Rambler American (1958-59)

① - For adjustment specifications and procedures, see *1955 & Earlier "Gemmer Worm & Roller" Steering Gear.*

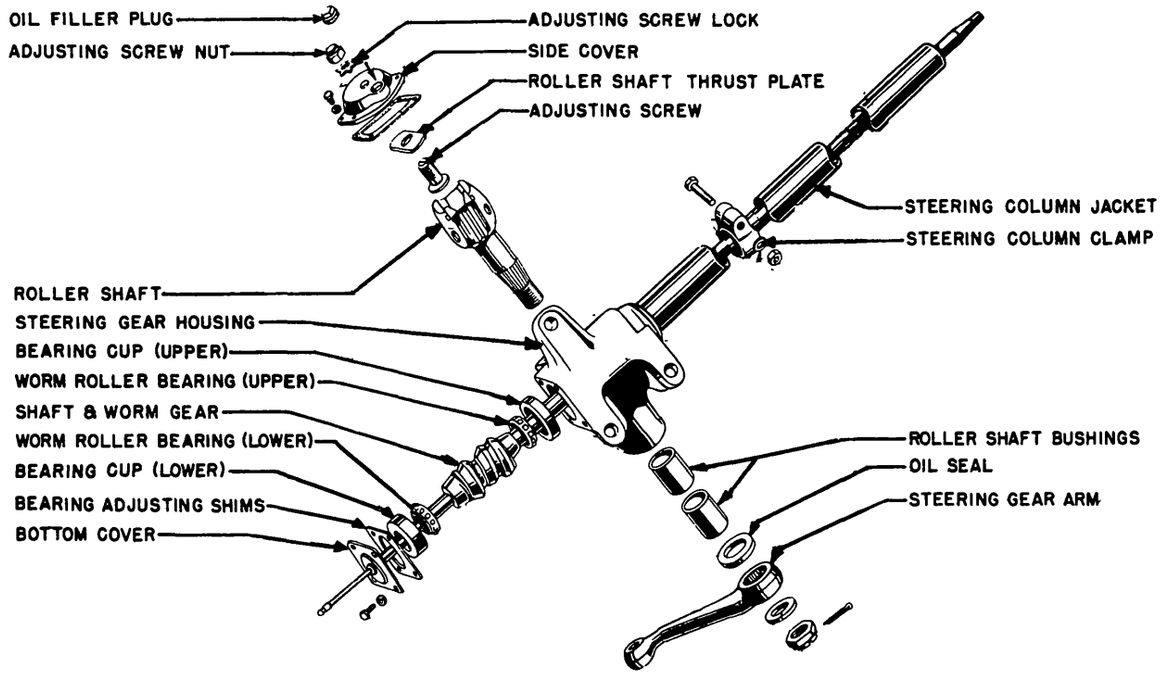
② - Saginaw Recirculating Ball Type steering gears used on some models.

►CHANGES, CAUTIONS, CORRECTIONS

►*1956 FORD & MERCURY STEERING GEAR PRODUCTION CHANGE:* In later production cars a steering gear having a three tooth roller supported on ball bearings is used. Service procedures are the same as for previous models.

►*1956 FORD STEERING COLUMN CLAMP BREAKAGE CORRECTION:* To prevent possible breakage of the steering column clamp, the tightening torque of the attaching bolt has been changed from 35-40 ft. lbs. to 25-30 ft. lbs.

►*1956 MERCURY STEERING GEAR PRODUCTION CHANGE:* Later production cars have a Saginaw Worm & Nut type steering gear. *See "Saginaw Ball Bearing Worm & Nut Steering Gear.*



►*1956 NASH AMBASSADOR SPECIAL V8 STEERING GEAR FILLER PLUG REMOVAL:* Because of the lack of clearance, the following suggested procedure is recommended: With car on hoist, a 5/8" socket and ratchet can be used to remove plug. Add lubricant with a hand gun having a long flexible nozzle.

►*1957-58 FORD TRUCK IDLER ARM LUBRICATION FITTING NOTE:* Idler arm lubrication fitting located inside left hand frame side rail. Lack of lubrication at this point will result in hard steering.

►*1959 CHRYSLER WINDSOR & DESOTO FIRESWEEP MANUAL STEERING GEAR MOUNTING PRODUCTION CHANGE & ALIGNMENT PROCEDURE CHANGE:* A new steering gear housing, Part No. 1946588 is being used in production and may be used for earlier 1959 cars to provide an improved method of aligning the the steering gear to frame side rail. In addition to the new housing, a new pivot bar and adjusting wedge is located between steering gear and frame, and a new spherical washer used on each of the three mounting bolts. *See "Steering Gear Alignment" below for new procedures.*

►*1959 PLYMOUTH MANUAL STEERING GEAR ALIGNMENT PROCEDURE (TO PROVIDE SMOOTH & EASY STEERING):* *See "Steering Gear Alignment" below.*

DESCRIPTION: Design is similar to that used on previous models. Beginning with 1959 models, a new roller shaft adjusting screw, secured in end of roller shaft with a snap ring, is used on some models.

GEMMER WORM & ROLLER STEERING GEAR

ADJUSTMENT: Before making adjustments, align steering gear as follows: Tighten body bolts, loosen steering gear at frame and dash bracket (to allow gear to move in relation to frame). **On Plymouth,** remove steering Wheel, *See "Steering Wheel & Horn Button Removal" below.* Remove steering column upper bearing spacer, then move steering column until it is tight against instrument panel, and steering gear until gear tube is centered in steering column upper bearing. **On all models,** insert metal shims between steering gear and mounting surface to eliminate bind. Tighten mounting bolts to 45-50 ft. lbs. **On Plymouth,** replace upper bearing spacer and steering wheel. **On Ford Trucks,** adjust steering column to obtain 1/16" clearance between top of column and steering wheel-hub, then tighten lower clamp.

Worm Bearing Adjustment: *NOTE* - There should be no vertical movement of steering shaft when wheels turned in both directions. To adjust worm bearings, remove steering gear arm, drain housing and disconnect horn wire at connector. Add or remove shims at lower grease retainer to eliminate endplay or to remove any bind in steering shaft. Adding shims increases endplay, removing shims reduces endplay.

Cross-shaft Endplay Adjustment: After making "Worm Bearing Adjustment" above, remove steering gear arm. Turn steering wheel back and forth to note any backlash between worm and gear. When backlash present, remove roller shaft adjusting screw locknut and tighten adjusting screw enough to eliminate backlash. Tighten locknut. *NOTE* - Be sure roller shaft and worm do not bind.

Roller Tooth & Worm Mesh Check: After completing above adjustments, install spring scale on steering wheel (at right angle to spoke) and check pull required to turn wheel through high point (half way from full right to full left turn). See table below for model specifications.

Model	① High Pull
Chrysler, DeSoto (1956-59)	1-2 lbs.
Dodge (1956-57)	7/8-1 5/8 lbs.
Dodge (1958-59)	② 10-18 inch lbs.
Ford Pass. Cars (Man. Strg.) (1956-59)	1-1 5/8 lbs.
Ford Pass. Cars (Pow. Strg.) (1956-59)	7/8-1¼ lbs.
Ford Trucks F-100, 250 (1956-59)	1-2 lbs.
Ford Trucks F-350 through F-600 (1956-59)	1¼-2 lbs.
Hudson & Nash (1956-57)	③
Packard (1956-57)	③
Plymouth (1956)	1-2½ lbs.
Plymouth (1957-59)	7/8-1 5/8 lbs.
Rambler (1956-57)	③
Rambler American (1958-59)	③

① - See OVERHAUL for worm bearing preload.

② - Inch Pound torque wrench on steering wheel nut.

③ - See "1955 & Earlier Gemmer Worm & Roller" Steering Gear for adjustment specifications and procedures.

STEERING WHEEL POSITION: *With steering at midpoint* (roller at high point on worm), intermediate steering arm (when used) should be on center line of car, wheels should point straight ahead, and steering wheel position should be correct as noted below.

Chrysler, DeSoto, Dodge, Plymouth: Master serrations on steering wheel hub, steering gear arm, steering tube and

CONTINUED ON NEXT PAGE

1956-59 GEMMER WORM & ROLLER (C ntinu d)

steering gear roller shaft, control steering wheel position for straight ahead front wheel position.

F rd Trucks: Install steering wheel with lower spoke straight down and steering gear on high spot of worm.

Rambl r Am rican: Install steering wheel (for straight ahead position) on steering shaft with mark on end of shaft at top center.

STEERING WHEEL & HORN RING REMOVAL & INSTALLATION: *NOTE - Wh r installation data is omitted b l w, r v rs r m val proc dure.*

Chrysl r, D S to: Disconnect battery, turn ornament counterclockwise and remove it. Disconnect horn wire from terminal, remove horn ring screws and bushings. then remove horn ring. Remove horn contact ring switch from steering wheel hub. Loosen steering wheel nut and pull steering wheel with Tool C-3428 or C-612.

D dge, Plym uth: Disconnect battery, center steering wheel in straight ahead position. Remove medallion screws (from under side of medallion) and remove medallion. Disconnect horn wire, remove horn ring, travel plate and insulator assembly, contact spring plate and ground plate. Remove steering wheel nut and pull wheel with Tool C-612

F rd Trucks: Disconnect horn wire at lower end of steering gear housing (Conventional models), disconnect horn wire at connector under instrument panel just beyond horn brush (Tilt Cab models). Remove horn button by pressing down and turning it counterclockwise. Remove horn button spring, button contact, and index spring. Remove steering wheel nut and index spring support. Install Puller Tool 3600-N (use holes tapped in steering wheel hub and with socket over horn wire for protection of wire), so pressure is against end of steering shaft and pull wheel from shaft. To install, be sure upper bearing and spring are in position at top of steering shaft, then press steering wheel on shaft.

Rambler American: Remove emblem or horn button, and pull steering wheel with Tool J-5290. To replace steering wheel, turn steering shaft until mark on shaft is at top center, then place wheel on shaft with steering wheel spokes equal distance from horizontal.

STEERING GEAR REMOVAL & INSTALLATION: *NOTE - Installation proc dur s ar the reverse for those for r moval.*

Chrysl r, D Sot (1956): *NOTE - It is not necessary to remov complete ste ring column and mast assembly.* Disconnect battery, then remove steering wheel and horn ring Loosen jacket bracket bolts at instrument panel and remove dust pad retaining screws Raise front of car and remove pitman arm from gearshaft. Loosen jacket to steering gear housing clamp bolt, then remove steering gear housing to frame side rail attaching bolts and carefully work steering gear column tube out of jacket tube Remove steering gear assembly from underside of car

Chrysl r, D Sot (1957-58): Disconnect battery ground cable Remove steering wheel, then disconnect horn and turn signal wires at instrument panel Remove jacket tube clamp at instrument panel, then remove dust shield at firewall and floor opening panel Remove pitman arm with Tool C-3402 Remove steering gear mounting bolts On Chrysler, slide steering gear jacket tube and remote control units rearward through drivers compartment as an assembly and remove brake pedal pad Remove steering gear from engine side of firewall On DeSoto, slide steering gear, jacket tube and remote control units rearward and remove them through drivers compartment

Dodge (1956-59), Plymouth (1957-59): Raise car and remove left front wheel Remove front seat cushion and floor mat, after sliding draft pad up column Remove steering column opening cover Disconnect direction signal control wires if so equipped *NOTE - With battery ground disconnected, tie a pull wire to control wires before removing them from jacket tube and leave pull wire to reinstall control wires* Remove transmission shifting mechanism at steering column (if so equipped) Remove bolts holding gear to frame and remove pitman arm with Tool C-3402 Remove steering gear and jacket cap at instrument panel Remove steering gear assembly through opening in floor pan

Ford Truck (Except Tilt Cab): Remove battery ground cable and disconnect horn wire at lower end of steering gear housing. Remove wire from clips on frame side member and fender apron. Loosen steering column lower clamp and slide it down. Disconnect transmission control rods at levers and remove steering wheel. *See "Steering Wheel & Horn Button Removal" above.* Remove steering column upper bushing spring and bushing. Disconnect turn signal wires and remove them from clip at instrument panel bracket. Remove steering column bracket clamps and rubber sleeve. On floor mounted gear shift lever trucks, pull steering column tube off shaft. On Fordomatic or remote-type gear shift lever trucks, remove steering shields from floor pan. On clutch equipped trucks, disconnect clutch retracting spring. Remove hydraulic cylinder bolts and move cylinder out of way. Remove steering gear sector arm (pitman arm) and remove steering gear housing mounting nuts and bolts. On floor mounted gear shift lever trucks, remove steering gear assembly from under truck. On Fordomatic or remote-type gear shift lever trucks, remove assembly through passenger compartment.

Ford Truck (Tilt Cab): Remove horn wire brush from steering column bracket just below instrument panel bracket. Remove upper universal joint retaining nut and bolt. Turn wheels to right and remove sector arm (pitman arm) retaining nut, bolt and arm. Remove housing to frame nuts and bolts, then remove steering gear with universal joint attached.

Hudson, Nash, Packard, Rambler (Exc. Rambler American): *See "1955 & Earlier Gemmer Worm & Roller" for removal procedures.*

Plymouth (1956): Remove steering wheel, then remove lower half of instrument panel bracket and loosen steering column jacket clamp Disconnect pitman arm and remove housing bolts at frame Hold steering column jacket and slide gear assembly out from below, leaving jacket and gearshift controls inside car

Rambler American: Remove steering wheel. *See "Steering Wheel and Horn Button Removal" above.* Loosen jacket tube clamp. Remove mounting bolts and remove steering gear without removing jacket tube.

STEERING GEAR ALIGNMENT (CHRYSLER, DESOTO, DODGE, PLYMOUTH): Different procedures as follows

1957-59 Chrysler, DeSoto, Dodge (Exc. Later 1959 Chrysler Windsor & DeSoto Firesweep With Later Typ Housing): Loosen steering gear at frame and at dash bracket or support to allow steering gear to move in relation to frame, then tighten mounting bolts to 45-50 ft lbs Position center of steering column in center of instrument panel or support If this cannot be done without moving the frame bracket, add metal washer shims between frame and frame bracket to eliminate all bind

1959 (Late) Chrysler Windsor & DeSoto Firesweep With Later Type Housing & Mounting: *NOTE - See "Changes, Cautions, Corrections" above* With steering gear installed in car, align steering gear and column jacket assembly to instrument panel jacket support, then install jacket support and tighten screw to 50 inch-pounds Install wedge between steering gear housing and frame at rear mounting bolt and tighten nut sufficiently to hold wedge in place Tighten steering gear housing to frame bolts to 50 ft lbs , alternately tightening rear and front mounting bolts gradually so that steering gear alignment is not disturbed Check complete unit for binding and for free movement

Plymouth (1957-59): To check gear alignment, remove steering wheel and remove steering column upper bearing spacer Turn front wheels from extreme right to extreme left and note rotation of steering tube in upper bearing *NOTE - It is not necessary that steering tube be in exact center of bearing, however, if tube is resting against bearing in any position, there should not be more than a ten lbs (spring scale) direct pull required to center the tube* If adjustment required, loosen steering column jacket clamp to-instrument panel nuts three or four turns Loosen the three steering gear-to-frame bolts sufficiently to allow free movement of steering column, then move steering column jacket upward until it is tight against instrument panel Move steering gear chuck until steering gear tube is centered in steering column upper bearing in a vertical direction Tighten steering gear-to-frame bolts to 50 ft lbs Move upper end of steering column jacket horizontally until steering gear tube is centered in steering column upper bearing If there is insufficient clearance at instrument panel to move steering column jacket horizontally, it will be necessary to shim between steering gear and frame as required to obtain sufficient horizontal adjustment Retighten steering column jacket clamp-to-instrument panel nuts Steering gear tube should now be centered in bearing Reinstall bearing spacer and steering wheel

CONTINUED ON NEXT PAGE

1956-59 GEMMER WORM & ROLLER (C ntinued)

OVERHAUL (STEERING GEAR ASSEMBLY): Disassembly - Mount unit in vise and remove gear shaft adjusting screw locknut, shaft cover, and gasket. Remove steering gear shaft and roller tooth assembly. Remove gear shaft oil seal from housing. Remove cover and shims from bottom of housing, then remove tube and worm assembly, bearing cups and cages.

Assembly - *NOTE - DO NOT lubricate any parts until unit is reassembled.* Replace all worn or damaged bearings and use new oil seals. On Chrysler and De Soto the housing is serviced with bushings. On Dodge and Plymouth, replace worn bushings. Bushings should be flush with ends of bore and the shorter bushing at outer end of housing. Ream new bushings to 1.250" for proper cross shaft fit. On Ford Truck, install bushings with Tool T57T-3567-A, and upper bearing cup with Tool T57L-4616-A2. Then insert worm and tube in housing with bearings and cups. Install shims and lower housing cover making sure bearings are seated. Tighten cover screws and install spring scale on temporarily installed steering wheel and check preload of worm bearings. See table below. Change shims as necessary. Install sector shaft. Turn adjusting screw on cover all the way out and install cover. Center steering wheel on high point and check high point (over-center) pull. See "Adjustments" above for specification. Turn adjusting screw in or out as required and secure locknut.

Model	Turning Pull
Chrysler, De Soto	3/8-3/4 lbs.
Dodge	① 3 1/2-7 inch lbs.
Plymouth	Remove all endplay without bind
Ford Trucks	1/4-3/4 lbs.

① - Inch Pound torque wrench on steering wheel nut.

1960 GEMMER WORM & ROLLER

Checker Superba (1960)
Chrysler (1960)
DeSoto (1960)
Dodge (1960)
Ford Trucks (1960)
Plymouth (1960)
Rambler American (1960)

►CHANGES, CAUTIONS, CORRECTIONS

►*CHRYSLER, DESOTO, DODGE, PLYMOUTH STEERING GEAR PRODUCTION CHANGE:* A new type steering gear is used on later production cars beginning approximately Jan. 20, 1960. The new type unit incorporates a flexible coupling between steering gear worm shaft and steering wheel shaft. Removal, installation and alignment procedures are different than for previous type units. See below.

►*1960 HARD STEERING OR GEAR BINDING CORRECTION:* The cross shaft adjusting screw retaining snap ring may have become unseated due to an oversize radius in bottom corners of snap ring groove which would prevent snap ring from seating properly. To correct, replace Shaft & Roller Tooth, Cross Shaft Cover, and Upper Bearing Assembly. *NOTE - This condition also applies to 1959 models.*

►*1960 CROSS SHAFT NEEDLE BEARING BREAKAGE CORRECTION:* Inspect steering gear housing cross shaft bore for concentricity. The correct diameter of housing bore is 1.4992-1.5002". If dimensions are not within these limits, replace steering gear housing. Clean and inspect all parts for damage and replace as necessary.

DESCRIPTION: Steering gear design is similar to that used on previous models. A new type roller shaft adjusting screw, secured in end of roller shaft with a snap ring is used on some models.

ADJUSTMENT: *NOTE - Adjustments must be made in the following sequence.*

Worm Bearing (Except Ford Trucks): Turn steering wheel about one turn from straight ahead position and secure wheel to prevent any movement. Determine endplay by shaking front wheels sideways noting any movement that may be felt between steering wheel hub and steering jacket tube. If endplay is present, adjust worm bearing by loosening the four bottom cover bolts about 1/8", then separate top shim with a knife blade and remove. *CAUTION - D n t mutilat r maining shims r gask t.* Tighten cover and recheck for endplay. *NOTE* - Remove only one shim at a time to prevent obtaining too tight an adjustment.

F rd Trucks - On all models, disconnect pitman arm from drag link (from control valve ball stud on models with power steering). On Tilt Cab models, remove lower universal joint retaining bolt and nut and raise steering shaft assembly off steering gear, then install a four inch block of wood between steering wheel and upper steering column tube flange. Bend a piece of light strap iron (10" long) so a 1" section is at right angles to longer section, then use a heater hose clamp and fasten strap iron to worm shaft so longer section of shaft forms a lever. Turn worm shaft two complete turns from straight ahead position and measure pull required to keep worm shaft moving at a constant rate for at least one complete turn, using a spring scale hooked to lever at a point 8½" from outer diameter of steering shaft. If pull required to turn shaft is not within specifications in table, adjust as indicated below. On other models, turn steering wheel two or three complete turns from straight ahead position, then install an inch-pound torque wrench on steering wheel nut and measure torque required to keep wheel moving at a constant rate for at least one complete turn. If torque or preload is not within specifications in table, adjust as indicated below. To adjust, disconnect horn wire at bullet connector just below steering column housing (except Tilt Cab models). Remove bolts attaching endplate to steering gear housing, then remove or install one gasket at a time to obtain the proper preload. Gaskets are available in thicknesses of .002", .005", .010". *NOTE - Removal of gasket will increase preload and installation of gasket will decrease preload.* To remove a gasket, separate outer gasket from pack by passing a knife blade all around inner face of gasket being careful not to cut or tear remaining gaskets in pack. Install endplate and recheck preload. *NOTE - On Parcel Delivery models the steering gear and column must be loosened before endplate can be removed for installation of gasket.*

Ford Truck Worm Bearing Setting

Model	Preload Setting
F-100, 250	2½-6¾ lbs.
F-350, 500, 600, B-500, 600	4½-9 lbs.
4-Wheel Drive	4½-9 lbs.
P-350, 400, 500	2¼-6¾ lbs.
C-550, 600	5-10 lbs

Cross Shaft Roller & Worm Mesh: Chrysler, DeSoto D dg , Plym uth - Disconnect pitman arm at link, then rotate steering wheel to mid position and check for backlash by moving pitman arm back and forth. If backlash exists, loosen roller shaft adjustment screw locknut and tighten adjusting screw enough to eliminate free play. Rotate steering wheel to one end of its travel and apply a spring scale at rim of steering wheel. A pull of 1-2 lbs. should be required to turn wheel. Tighten adjusting screw locknut while holding adjusting screw from turning.

Ford Trucks - With bearing preload adjustment completed (see above), check effort required to pull steering wheel, or lever through center (high point). If turning effort is not within specifications (see below), place steering gear on "high point", then, on medium or heavy duty trucks, loosen adjusting screw locknut at engine side of steering housing. On light duty models, remove locknut and star washer, then adjust worm and roller mesh by turning adjusting screw clockwise to tighten mesh, or by turning it counterclockwise to loosen the mesh. On light duty models, replace locknut and washer. On all models, tighten locknut, then recheck turning effort.

Ford Truck Pitman Shaft Setting

Model	Pr load Setting
F-100, 250	9-18 lbs.
F-350, 500, 600, B-500, 600	13½-22½ lbs.
4-Wheel Drive	13½-22½ lbs.
P-350, 400, 500	11¼-18 lbs.
C-550,600	13½-22½ lbs.

STEERING WHEEL & HORN BUTTON REMOVAL: Chrysler & DeSoto - Disconnect battery, then press down on center steering wheel ornament and turn ¼ turn to remove. Disconnect horn wire and remove three screws, bushings, horn blowing ring, rubber insulator and horn terminal plate. Loosen steering wheel nut three turns and use puller, Tool C-3428 to loosen steering wheel. Remove tool, wheel nut and wheel.

Dodge & Plymouth: Disconnect battery ground cable, then remove steering wheel ornament by removing the screws from underside of wheel. Remove stationary plate, bushings, horn ring and attaching sorews. Disconnect horn wire at stationary plate, then loosen steering wheel nut three turns and use puller, Tool C-3428 to loosen wheel.

Ford Trucks: Disconnect horn wire at bullet connector below steering gear housing (under instrument panel on Tilt Cab models), then remove horn button by pressing down and turning it counterclockwise. Remove horn button spring, button contact, and index spring. Remove steering wheel nut and index spring support. Install Puller 3600-N in tapped holes of steering wheel hub, then place an adaptor over end of horn wire so that pressure of puller is against end of steering shaft

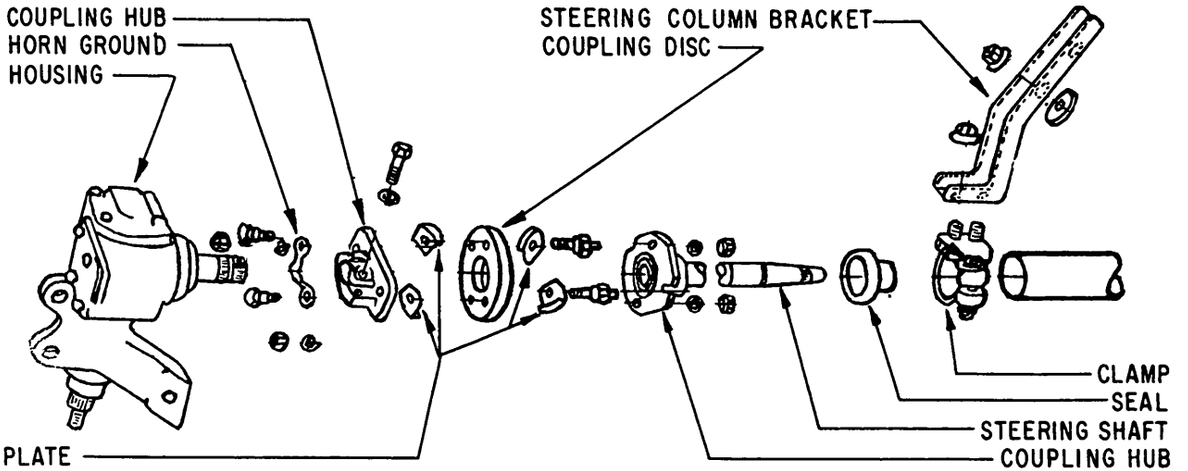
CONTINUED ON NEXT PAGE

1960 GEMMER WORM & ROLLER (C ntinu d)

and not on horn wire fibre washer and remove steering wheel.

Rambl r Am rican: Remove horn button or horn ring and pull steering wheel with Tool J-5290. To replace steering wheel, turn steering shaft until mark on shaft is at top center, then place wheel on shaft with steering wheel spokes equal distance from center.

STEERING GEAR REMOVAL, INSTALLATION & ALIGNMENT: Note the special alignment procedures outlined below.



Chrysler, D S t , D dg , Plymouth (Early Type Unit With ut Fl xibl Coupling): Removal - Disconnect battery ground cable, then remove steering wheel. Disconnect directional signal indicator and horn wires at connectors. On Chrysler and DeSoto, remove directional signal switch. On Dodge and Plymouth, remove directional signal indicator lever (threaded in). On all models, remove screws attaching steering jacket tube clamp at instrument panel and remove clamp, then raise carpet and move rubber grommet up on jacket. Remove screws attaching steering jacket tube clamp at steering housing. Disconnect pitman arm from sector shaft with Tool C-3646, then disconnect hydraulic brake line at master cylinder and brake tee and remove line. Slide steering gear jacket tube rearward and remove it through drivers compartment. Remove tapered retainer and spring from column tube, then remove steering gear housing to frame bolts and slide gear to rear of car and at same time raise lower end of gear up. Remove steering gear through hood assembly.

Installati n & Alignm nt - Install steering gear assembly in engine compartment and through opening in floor panel, then install housing bolts with rounded "D" bar between frame and forward mounting pad of housing. *NOTE - Flat sid of round d "D" bar must be toward fram .* Install flat washers, spherical washers and nuts, but do not tighten. *NOTE - Convex side of spherical wash r must b against gear housing.* Install bearing spring and tapered retainer on column tube, then slide jacket tube down against shoulder on housing. Raise tube 1/8" and tighten bolts to 15 ft. lbs. Install jacket tube clamp at instrument panel and tighten screw to 50 inch pounds. Connect directional signal wires and horn wire at connectors, then install turn signal switch (Chrysler & DeSoto). Install steering wheel and tighten nut to 40 ft. lbs. On Dodge and Plymouth, install directional signal lever. On all models, measure distance between steering column jacket tube and steering wheel. If distance is less than 1/8", loosen clamp bolt and adjust column jacket to obtain proper clearance. Install horn assembly (see above), then tighten jacket tube to instrument panel clamp screws and install dust shield. Tighten front upper and lower gear housing to frame attaching bolts to 20 ft. lbs., then install a wedge over rear bolt between housing and frame so that tapered surfaces match, tapping it lightly into place, and tighten the three attaching bolts to 50 ft. lbs. alternately. Install pitman arm and tighten nut to 125 ft. lbs. Reinstall brake line between master cylinder and brake tee and bleed brakes as necessary.

Chrysl r, D Sot , D dg Plym uth (Lat Typ Unit With Fl xibl C upling): R m val - Remove pitman arm from sector shaft with Tool C-3646, then remove flexible coupling to steering gear worm shaft attaching bolt and washer. Remove steering gear to frame side rail attaching bolts and slide gear assembly forward to disengage flexible coupling from worm shaft. Raise gear and remove through engine compartment.

Installation - Place steering gear worm shaft on exact center of travel (high point). Mark master spline in outer row of serrations on worm shaft, then install gear in engine compartment. Align index mark on outside of flexible coupling hub with master spline on worm shaft. Slide coupling on worm shaft and install gear housing to frame attaching bolts and tighten bolts evenly to 50 ft. lbs. Position flexible coupling bolt hole in line with groove on worm shaft and install bolt and lock washer and tighten to 30-35 ft. lbs. Install pitman arm and tighten nut to 125 ft. lbs.

Alignment - Check steering tube for alignment in steering column seal. If tube is not centered, proceed as follows: *NOTE - Steering tube must be centered in steering column seal, also lip of seal which contacts tube must be well lubricated with wheel bearing lubricant.* Loosen steering column clamp bolts at instrument panel, then loosen lower column clamp bolt and support bracket at both firewall and at column clamp. Hold steering column so it is centered on tube while aligning column support bracket to fireawll and lower column clamp. When properly located, tighten support bracket stud nuts at firewall and at column clamp to 50 inch pounds. Tighten steering column to instrument panel clamp bolts to 15 ft. lbs., then tighten lower steering column clamp bolt to **200 inch pounds.**

CHRYSLER, DESOTO, DODGE, PLYMOUTH STEERING GEAR (WITH FLEXIBLE COUPLING)

Ford Trucks (Exc. Tilt Cab & Parcel Delivery Models): Disconnect battery ground cable, then disconnect horn wire from bullet connector below steering gear housing and remove wire from clips on frame and fender apron. Loosen steering column lower clamp and slide clamp down. Disconnect transmission shift control rod or rods at shift levers. Remove steering wheel (see above), then remove steering column upper bushing spring and bushing. Disconnect turn signal wires, and remove from retaining clip at instrument panel bracket. Remove steering column bracket clamps and rubber sleeve. If truck has a floor mounted gear shift lever, pull steering column tube off shaft. On a truck with automatic transmission or a remote type gearshift lever, remove steering column shields from floor pan. If truck has a V8 engine, remove engine oil filter. On a clutch equipped truck, disconnect clutch retracting spring, remove clutch hydraulic cylinder retaining bolts, and move cylinder out of way. Remove steering gear pitman arm. Disconnect steering gear from frame side rail. On a model with floor mounted gearshift, remove steering assembly from under the truck. On models with automatic transmission or a remote type gearshift, remove assembly through passenger compartment. If steering column tube has not been removed, loosen lower clamp and remove tube. To install, reverse removal procedure.

Ford Trucks (Tilt Cab Models): Remove the horn wire brush from steering column just below instrument panel bracket. Remove universal joint upper retaining nut and bolt, then turn wheels to right and remove pitman arm. Remove steering gear housing to frame bolts and remove steering gear with universal joint attached. Install by reversing removal procedures.

Ford Trucks (Parcel Delivery Models): Remove the steering wheel (see above), then remove steering column bracket bolts from instrument panel. Raise front of truck and install stands, then remove pitman arm. Loosen steering column lower clamp, and disconnect horn wire. Move steering gear to left and remove it from beneath truck.

Rambler American: Removal - Remove steering wheel (see above), then loosen jacket tube clamp. Remove pitman arm from steering shaft. Remove steering gear mounting bolts and remove steering gear without removing jacket.

Installation - Reverse removal procedures.

OVERHAUL: *See "1956-59 Gemmer Worm & Roller" and note the following:*

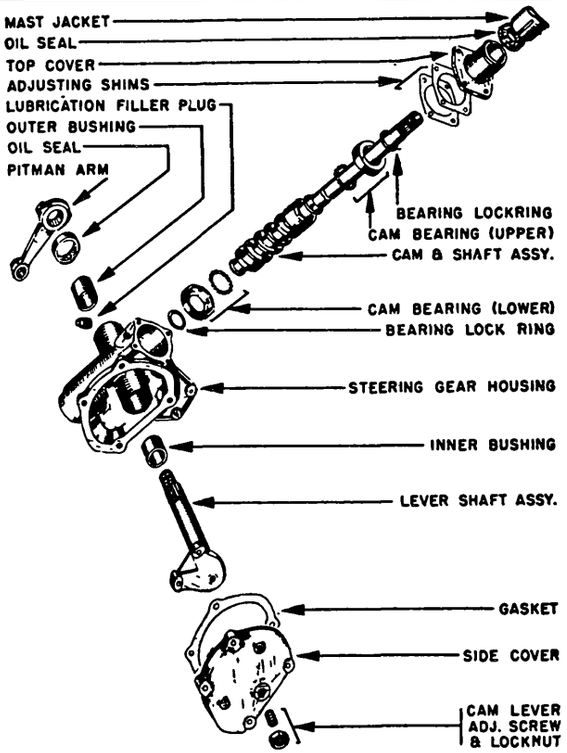
R ll r Shaft Adjusting Scr w: On some steering gear models, the adjusting screw is secured in end of roller shaft with a snap ring. To remove screw, remove snap ring.

ROSS CAM & TWIN LEVER

Stud bak r, All Mod ls (1954-56) ①
Studebaker, 6 Cyl. Models (1957-60) ②
Willys Utility (1954-60)

① - Saginaw Worm & Roller also used.
② - Ross Model SL-54 used on some models.

DESCRIPTION:—Consists of a worm-shaped cam mounted on the steering column shaft engaging two tapered studs mounted on the inner end of the cross-shaft lever. Cross-shaft is mounted on plain bushings and is adjustable for end-play. Cam is mounted on ball thrust bearings at upper and lower ends and bearing clearance or endplay is adjustable. Stud track in cam is grooved deeper at ends to provide minimum clearance at each stud in 'straight ahead' position. All adjustments must be made with wheel in straight ahead position.



ADJUSTMENT

ADJUSTMENT:—Before making adjustments, free steering gear from load by jacking up front wheels or disconnecting drag link. Check the gear alignment. If stiffness evident with instrument panel bracket clamp tight, align steering gear as follows: Loosen steering gear frame bracket bolts to allow gear to shift on frame, retighten frame bolts. Loosen instrument panel bracket bolts to allow bracket to shift into alignment with steering column, tighten bracket bolts (if bracket position not adjustable, shim or otherwise change bracket position so that column not sprung when bracket bolts tightened).

Cam Endplay Adjustment—Check up-and-down movement of steering wheel and shaft in steering column jacket. If adjustment required, first loosen locknut and back off adjusting screw on housing side cover to relieve bearings of side thrust. Then remove four retaining screws in top cover on upper end of steering gear housing, move cover up on column jacket as far as possible (about ¼"), clip and remove a thin shim in shim pack under cover (shims are installed between paper gaskets and are .003", .010", .030" or .002", .003", .010" thick), using extreme care not damage remaining shims and paper gaskets. Re-install cover, tighten cover screws, check adjustment. Wheel should turn with barely perceptible drag (4-7 ozs. pull on steering wheel rim) and should have no up-and-down movement. Then adjust Cam and Lever Backlash.

Cam and Lever Backlash—Check end-play or lost-motion of lever shaft at pitman arm with steering gear turned to center position with lever studs on high points of cam. If play evident, adjust by loosening locknut on steering gear housing side cover and turning adjusting screw in until play just taken up and steering wheel turns freely throughout entire range with drag at center high point 16-24 ozs. at steering wheel rim. Hold adjusting screw and tighten locknut.

►*CAUTION*—This adjustment must be made only with lever studs on high points of cam (straight ahead position). If adjusted in any other position, gear will bind at this center point.

ROSS CAM & TWIN LEVER STEERING GEAR

STEERING WHEEL & HORN RING OR BUTTON REMOVAL

Studebaker (All Models): Removal - Proceed as indicated below.

Models With Horn Button - Push down on button and rotate one-third turn, then remove retaining nut and plate and remove wheel with Puller J-5473.

Models With Horn Ring - Pry cap out of wheel, then remove ring retaining screws and insulators. Remove wheel retaining nut and lock plate and remove wheel with Puller J-5473.

Installation (All Models) - Align marks on wheel hub and on shaft and install wheel. Tighten wheel nut to 23-27 ft. lbs., then complete installation by reversing removal procedure.

Willys (1954-60): Removal - Disconnect horn wire at slip connection just below steering gear housing. Remove steering wheel hub cover by turning clockwise 1/8 turn to disengage it. Remove flat spring from slots in horn ring cup and pull up horn wire sufficiently to remove contact button, sleeve, spring and cup. Remove steering wheel nut, then install Puller W-227 and remove wheel.

Installati n - Reverse removal procedure.

STEERING GEAR REMOVAL & INSTALLATION

Stud bak r (1954): Remove horn button and steering wheel, then remove front seat cushion. Remove battery and, if equipped with automatic transmission, disconnect shift panel light and starter safety switch cable. Disconnect shift lever rods, then loosen jacket clamp bolt and remove jacket from steering post. Disconnect pitman arm at drag link and remove bolts holding gear to frame. Tip upper end of steering post down and remove steering gear assembly from engine compartment.

Installation - Reverse removal procedure.

Studebaker (1955): Disconnect battery and disconnect horn switch wire at connector. On Commander & President models, also disconnect battery cable at starter switch. On Commander and President Convertible (Hardtop) and Coupe models, remove battery and battery box. Remove steering wheel and steering post jacket assembly (*NOTE*—Steering gear housing, steering post jacket, and steering wheel can be removed as an assembly. However, on Commander & President Convertible (Hardtop) and Coupe models, it will be necessary to remove left front engine support cushion and raise left front corner of engine approximately 2"). Remove pitman arm using puller J-5664, then remove steering gear housing-to-frame bolts and remove steering gear through hole in dash and into car. Wrap a cloth around steering gear housing top cover to prevent spilling lubricant during removal. To install, reverse removal procedure. Before installing jacket and gearshift shaft assembly, install housing-to-frame bolts but do not tighten until jacket and jacket-to-instrument panel bracket bolts have been installed. Check alignment of housing mounting flange face with frame side rail, inserting washers as necessary to secure proper alignment and high spot adjustment.

Studebaker (1956-58): Removal and installation procedures are the same as for 1955 models except that battery and battery box must be removed on all Hawk Models.

Studebaker (1959-60): Disconnect and remove battery and disconnect horn wire at connector. Disconnect battery cable from starter. On Hawk models, remove battery box. Remove steering wheel and steering post jacket assembly. *NOTE - On all V8 mod ls except Hawk, remove left front engine support cushion stud nut and raise left front corner of engine 1½" (r move distributor cap to prevent damage).* Disconnect pitman arm at drag link, then remove bolts attaching steering gear to frame. Roll gear over so it is upside down and remove it through engine compartment.

Willys Utility Models (1954-55): On models with remote control, disconnect shift rods from levers on transmission. On all models, remove steering wheel, horn button, and steering post bracket, then on models with remote control, remove shift levers at lower end of steering column. Disconnect pitman arm from steering

CONTINUED ON NEXT PAGE

ROSS CAM & TWIN LEVER (C ntinu d)

connector rod and remove bolts attaching steering gear to frame. Remove steering gear assembly by dropping it down through floor pan and over outside of frame side rail. *NOTE - On Jeep models, remove left front fender.* To install, reverse removal procedure.

Willys Utility Mod ls (1956-60): Remove left front fender and disconnect transmission remote control rods (if equipped). Remove steering wheel (see above). Remove steering post bracket at instrument panel, remote control gearshift lever, and exhaust pipe from manifold. Remove cover plate on toe board. Remove screws holding remote control housing to steering column and disconnect horn wire, then remove remote control housing down through floor pan. Remove steering connecting rod from steering gear arm ball. Remove steering gear housing attaching bolts and remove assembly from below and over frame side rail. To install, reverse removal procedure.

Willys Forward Control Models (1957-60): Remove direction signal control assembly from steering column, then remove floor access panels at base of steering column. Disconnect clutch cable from pedal shaft and remove lower left panel from instrument panel. Remove steering column clamp, then loosen radiator screen and swing it down for access to steering gear. Disconnect pitman arm from connecting rod and remove steering gear mounting bolts. Disconnect horn wire and remove steering gear assembly by pulling it up and out of cab. To install, reverse removal procedure.

OVERHAUL (STEERING GEAR ASSEMBLY): Disassembly—Loosen cam lever adjusting screw locknut, back off adjusting screw two turns. Remove side cover screws and washers, remove side cover, drain lubricant from housing. Remove pitman arm, then cam lever shaft from housing. Remove upper plate cover screws, then remove cover, lower oil seal, and adjusting shims. Withdraw post and cam assembly from housing. Remove ring from lower end of cam to permit removal of lower cup and ball bearings. Remove upper bearing cup ring, bearing cup, and ball bearings. Remove oil seal and gasket from cam lever shaft bore and, using a suitable arbor, press inner and outer bushings out.

Reassembly: With suitable arbor, press bushings into place in cam lever shaft bore of housing. Bushings should be line-reamed to fit cam lever shaft. Assemble cam bearings, cup, and rings on cam and post assembly, install assembly in housing. Assemble top cover and shims on housing, check bearing adjustment, remove or add shims as required. Install cam lever shaft, housing cover gasket, and cover, tighten cover screws securely. Install lever shaft gasket and oil seal, install pitman arm.

STEERING LINKAGE: *See "Steering Linkage."*

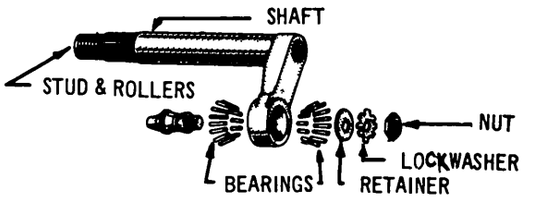
ROSS MODEL SL-54

Packard (1957-58)
Stud bak r V8 (1957-60)
Stud baker 6 Cyl. (1958-60)Ⓒ
Ⓒ - Used on some models.

DESCRIPTION: Similar in design to Ross Cam & Twin Lever except for the single cam lever with tapered roller bearing mounted follower

Adjustm nt: The steering post and cam lever endplay adjustments are made in the same manner as for the Cam & Twin Lever Type. *See "Ross Cam & Twin L v r" St ering G ar.*

Disass mbly: Same as for the Cam & Twin Lever except as follows:



1) To remove follower from lever, bend down locking tang, remove the nut, lockwasher and plain washer. Then slip the bearings and follower out of the cam lever.

Reassembly: Same as for the Cam & Twin Lever except as follows:

1) To reassemble the cam lever, place lower set of bearings around the cam follower; hold them in place by means of heavy grease. Then carefully insert follower and bearings into the lever. Hold the follower in position and install the upper set of bearings. Install washer, lockwasher, and nut.

2) Adjust the cam follower bearing as follows: Hold cam follower and tighten the adjusting nut sufficiently so that cam follower can be turned by hand with a slight drag. This check should be done with the unit lubricated. Bend locking tang to hold adjusting nut securely in place.

Adjustment: The steering post and cam lever end play adjustments are made in the same manner as for the Cam & Twin Lever type.

CAM LEVER SHAFT ASSY.

SAGINAW WORM & ROLLER

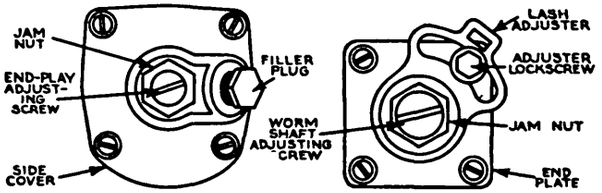
Pontiac 6 & 8, All Models (1954)

►CHANGES, CAUTIONS, CORRECTIONS

DESCRIPTION: Hour-glass type worm and double tooth roller of same design used on previous models.

ADJUSTMENT

ADJUSTMENT: Disconnect steering connecting rod from pitman arm. Torque pitman arm nut to 110-125 ft. lbs. Loosen steering post bracket to be sure it is not sprung. If misaligned, shim at steering gear housing-to-frame bolts, tighten bracket.



Roller Shaft Endplay: Tighten four side cover-to-housing bolts, loosen adjusting screw jam nut, turn steering wheel to end position, then tighten adjusting screw securely, using offset screwdriver. Back off adjusting screw until it is free, then again turn it in until screw can just be felt to be bearing against shaft. Keep screw from turning, tighten jam nut. Test for endplay. No endplay should be felt when attempting to move pitman arm in or out but arm should be free without bind when moved radially.

Worm Shaft Endplay: Tighten three bolts holding end plate to housing. Do not tighten adjuster lock bolt. Loosen worm thrust screw nut. With steering gear turned to end position, near but not against stops, tighten worm thrust screw to obtain a pull at steering gear rim as indicated in following table. Tighten lock nut.

Car Model	Worm Bearing Setting
Pontiac	3/8-5/8 lb.

Worm & Roller Backlash: Disconnect drag link from pitman arm. Loosen lash adjuster lock bolt (in the slot through adjuster). Center the steering gear so steering wheel in straight ahead position. Tap lash adjuster plate lightly to turn it in direction of arrow until a pull is secured at steering wheel rim as indicated in following table. CAUTION—Lash adjuster plate should not be moved more than 1/16" (in relation to lock bolt) at a time and in no case should a tighter adjustment than maximum limits in table below be made as damage to gear may result). Tighten lash adjuster lock bolt securely. Check adjustment. Move steering wheel through entire travel right and left to check for tight spots. If tight spots found on both sides of central position, loosen lash adjuster lock bolt, tap lash adjuster plate opposite direction of arrow just enough to bring pull at tightest point between limits indicated in table. If tight spot only on one side of wheel center position, adjust gear for maximum pull (see table)

CONTINUED ON NEXT PAGE

SAGINAW WORM-AND-R LLER TYPE ADJUSTMENTS

SAGINAW WORM & ROLLER (C ntinu d)

through tight spot. Then with wheel in center of the high spot, remove wheel and reinstall it with spokes in straight ahead position (must not vary more than 5 degrees from horizontal when front wheels straight ahead). Reconnect drag link to pitman arm keeping steering wheel in straight ahead position and worm on high spot. Place wheels in straight ahead position by adjusting the tie rods.

Car Model	Backlash Setting
Pontiac	1¼-1¾ lbs.

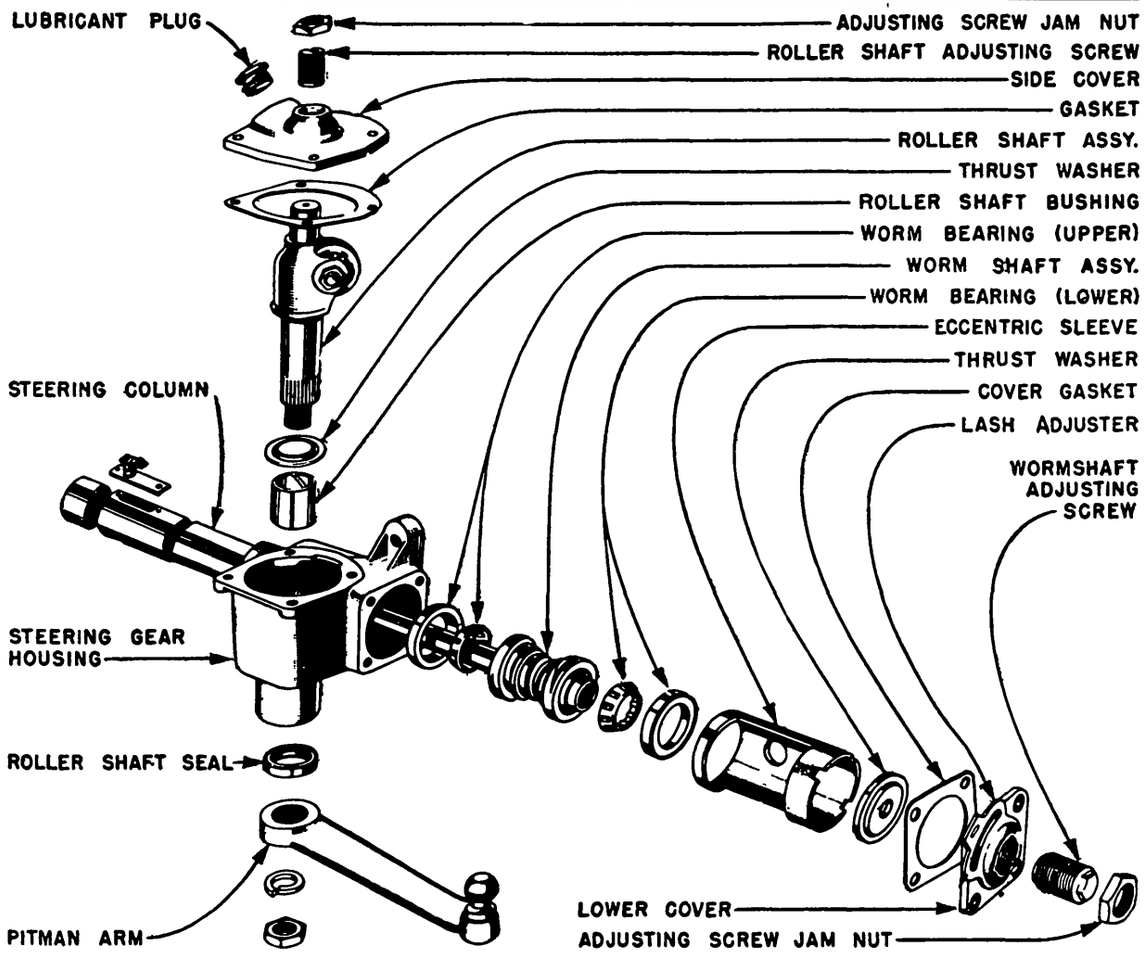
STEERING WHEEL & HORN RING OR BUTTON REMOVAL

Horn Button Removal (Plain Button Type). Press down on one side of button which will cause opposite side to rise. Insert screwdriver and remove button.

Horn Button Removal (Ring Type). Disconnect horn wire at relay. Remove horn button cap by lifting out of wheel, then remove steering wheel nut and washer. Remove horn sounding ring assembly from steering gear.

Installation—Assemble horn ring assembly in steering wheel by tilting the top end down so that upper rubber spacer engages retaining lug in steering wheel hub, then pull lower end of ring down into position by sighting through cap hole. Particular care should be taken to locate the pilot hole in contact onto shoulder provided in the insulated connector. Install steering wheel nut and lockwasher and push button cap into position. Connect horn button wire.

Horn Ring Removal (Deluxe Type) - Remove horn ring cap by turning slightly to left and lifting out. Remove steering wheel locknut and lift out horn ring assembly, then remove horn insulator and contact and spring assembly.



Steering Wheel Removal - Install Puller J-3034 and remove steering wheel.

Steering Wheel Installation: Reverse removal procedure. Torque wheel nut to 25-30 ft. lbs. and locknut finger tight plus ¼ turn.

STEERING GEAR REMOVAL & INSTALLATION

Removal: Remove steering wheel and disconnect direction signal wire harness at connector plug under instrument panel. Remove steering column and pedal upper and lower plates, then remove horn wire and neutral safety switch wire. Remove gearshift lever. Raise car and place supports under both lower control arms. Remove left hand side apron, then remove pitman arm from shaft with a suitable puller. Remove all steering gear attaching bolts except front upper bolt. Remove bolts holding steering column lower bracket to upper bracket on instrument panel and remove rubber grommet. Remove remaining steering gear attaching bolt and remove gear by bringing it down through floorboard and over linkage toward right front wheel. *NOTE - Be sure to save shims found between frame side rail and steering gear.*

Installation: Reverse removal procedure and note the following: Replace same shims (found when gear removed) between steering gear and frame.

SAGINAW WORM & ROLLER STEERING GEAR

STEERING GEAR OVERHAUL

Disassembly: Remove pitman arm using puller No. C-47. Remove side cover plate from housing and take out pitman shaft, then loosen "jam nut" and back out worm shaft adjusting screw from end of worm shaft. Remove endplate from housing and push worm and shaft assembly down through bottom of housing, removing eccentric sleeve, worm and bearings.

Inspection and Cleaning: Wash all parts in clean solvent and inspect for wear, pitting or roughness.

Reassembly: Assemble two tapered roller bearings on worm shaft and eccentric sleeve over bearings. Put lower thrust washer in place inside eccentric sleeve to hold bearings in place. Start worm shaft adjusting screw into endplate, then install endplate on housing and attach with four capscrews. (NOTE—Worm shaft adjusting screw should be screwed in just enough at this time to hold bearings in place. Proper adjustment will be made later). Slide pitman arm shaft in place and attach side plate to housing. Install endplay adjusting screw and locknut.

Testing & Adjusting on Bench: Secure steering gear in vise and place steering wheel on shaft. Turn steering gear from one extreme to opposite to make certain there are no unusual binds. Adjust steering gear as outlined under ADJUSTMENT above.

STEERING LINKAGE: *See "Steering Linkage".*

1954 SAGINAW (CHEVROLET) PASS. CARS

Chevrolet Pass. Cars (1954)

DESCRIPTION: Hour-glass worm and roller sector type with worm gear on steering column shaft meshing with double-tooth roller on cross-shaft (sector shaft).

ADJUSTMENT

ADJUSTMENTS: *NOTE*—Before disconnecting steering connecting rod from pitman arm, take care to note relative positions of steering connecting rod parts before disturbing them. Then proceed as follows:

Worm Shaft Endplay: Remove sheet metal splash guard covering steering gear housing, disconnect connecting rod from pitman arm (CAUTION—note relative positions of connecting rod end parts to insure correct reassembly). Loosen adjusting screw locknut on housing cover, back off lash adjuster screw several turns to provide clearance between worm and roller. Turn steering wheel to within one turn of either end position (turn wheel as far as possible, then turn wheel in opposite direction about one turn). Use spring scale (J-544-A Checking Scale) hooked to wheel spoke at rim to measure pull required to keep wheel in motion.

Bearing Pre-load—⅜-⅝ lb. turning pull (above).

Adjustment—Loosen large adjusting cup locknut on lower end of steering gear housing, turn adjusting cup in until worm shaft has no perceptible endplay. Check pull required to turn wheel (above), tighten locknut when turning pull of ⅜-⅝ lb. is secured. *CAUTION—Recheck pull after locknut tightened.*

Worm & Roller Mesh (Backlash): Place steering wheel in exact center of travel with roller on minimum-lash point of worm (count number of turns of wheel from one end position to the other, then turn wheel back ½ this number of turns, remove horn button and make certain that mark on end of shaft points upward, mark steering wheel for reference while making adjustments). Turn lash adjuster screw on housing cover clockwise until all lash removed from worm and roller (NOTE—this screw was loosened in making worm shaft endplay adjustment above), then tighten adjuster screw locknut to 10-15 ft. lbs. Check adjustment by turning wheel one half turn off center "high" spot, attach spring scale at wheel rim and note pull required to turn wheel through the center position.

Backlash Setting—⅞-1⅞ lbs. pull to turn steering wheel through center position (measured as above). **Adjustment**—With steering wheel turned one-half turn off center "high" position, loosen lash adjuster screw locknut, turn lash adjuster screw on housing cover clockwise to decrease backlash (and increase required pull), or counter-clockwise to increase backlash (and decrease required pull), tighten locknut, connect steering connecting rod. *CAUTION—Final steering gear setting must be within ⅞-1⅞ lbs. pull (measured as above).*

Horn Button Removal: On models equipped with horn button, pry off horn button or ornamental cap.

Horn Ring Removal: On models equipped with horn ring, remove screws holding pivot ring, then remove pivot ring, lock ring and horn blowing spring washer.

Steering Wheel Removal: Remove steering wheel nut and washer. Using steering wheel puller J-2927, thread puller anchor screws into threaded holes provided in steering wheel hub.

Steering Wheel Installation: With steering gear on high point, install steering wheel, with spokes horizontal. Install washer and nut, torque tighten to 25-30 ft. lbs.

STEERING GEAR REMOVAL

REMOVAL OF STEERING GEAR: Remove horn button or cap in center of steering wheel, remove wheel retainer nut and washer from upper end of shaft. If car equipped with horn blowing ring, take out screws holding pivot ring, remove pivot ring, lock ring, and horn blowing spring washer. Use Puller J-2927 (has anchor screws which thread into holes in wheel hub) to remove steering wheel. Remove upper control shaft clamp bolt from shaft connector, remove toeboard grommet and seal. Remove instrument panel mast jacket clamp by taking out nuts and lockwashers. Remove two clutch-head screws attaching gearshift control upper support to mast jacket, pull upper control shaft and support up to disengage shaft connector and remove these parts. Remove clamp bolt nuts and clamp retaining shifter housing on mast jacket, rotate shifter housing assembly away from mast jacket. Remove sheet metal splash guard over steering gear housing, remove steering gear mounting bolts. Remove air duct by taking out sheet metal screws attaching duct to left fender skirt. Rotate steering gear to clear fender skirt, then raise assembly up and forward and remove it from engine compartment.

►**Installation Note**—Reverse removal directions given above and note following points:

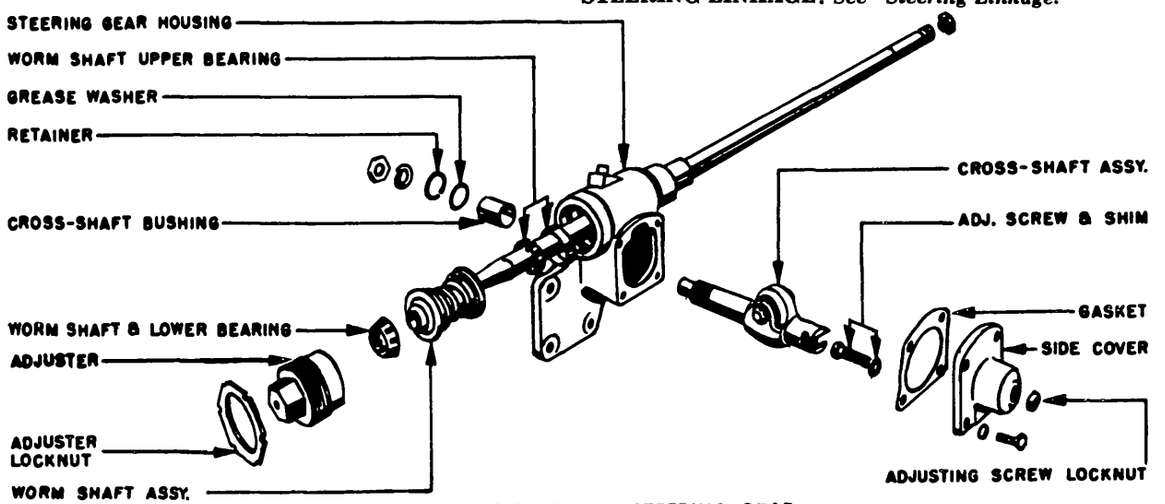
Steering Gear Mounting Bolts—Tighten housing to frame side rail bolts to 27-40 ft. lbs.

Steering Wheel Position—Turn shaft to center "high" point with mark on end of shaft upward, install steering wheel with spokes horizontal, tighten retainer nut on shaft to 25-30 ft. lbs.

STEERING GEAR OVERHAUL

Disassembly: Remove nut and lockwasher on end of sector shaft, use Puller J-1025 to remove pitman arm. Loosen lash adjuster screw locknut and turn adjuster screw several turns counter-clockwise, loosen worm bearing adjuster cup locknut and turn adjuster cup several turns counter-clockwise to remove load from bearings. Take out housing side cover attaching bolts, remove cover as an assembly with the sector shaft and roller (NOTE—If roller does not clear opening in housing, turn worm shaft by hand until roller lines up with notch). Remove worm bearing adjuster cup, withdraw lower bearing, pull worm and shaft out through lower end of housing (CAUTION—protect worm from damage). Remove locknut from lash adjuster screw, remove screw from side cover, slide screw out of slot in end of sector shaft.

Inspection & Repair: Wash all parts in cleaning solvent. Inspect roller bearings, bearing cups, worm, and roller for cracks, pits, roughness and wear.



Sector Shaft Bushing & Packing Replacement—To replace bushing, press bushing, packing, and retainer out of housing in an arbor press using J-1614 driver. Press new bushing in place using same driver. Soak new packing in engine oil, install packing in retainer, press assembly into housing.

Wormshaft Bearing Cup Replacement—Use Mainshaft Bearing Cup Remover J-3183 to pull cup from steering gear housing and from worm bearing adjuster cup. Install new bearing cups with Bearing Cup Replacer J-3182 (install cup on tool and drive into place using great care not to crack cups).

Lash Adjuster Screw Clearance Adjustment—With screw and shim assembled in slot in end of sector shaft, check end clearance of screw in slot with a feeler gauge. If clearance greater than .002", adjust by installing shim of correct thickness.

Reassembly: Reverse disassembly directions given above.

STEERING LINKAGE: *See "Steering Linkage."*

CHEVROLET PASS. CAR STEERING GEAR

SAGINAW (STUDEBAKER) WORM & ROLLER

Studebaker, All Models (1954-56)

DESCRIPTION: Hour-glass worm and roller sector type with worm gear on steering column shaft meshing with double-tooth roller on cross-shaft.

ADJUSTMENT: Two adjustments required (complete procedure must be followed). Proceed as follows:

Worm Shaft Endplay: Disconnect steering reach rod from pitman arm, loosen steering post jacket bracket-to-instrument panel bolts. Loosen lock nut and turn adjusting screw a few turns counterclockwise to remove load from worm shaft bearings. Turn steering wheel gently in one direction until stopped by gear, then back away one turn. Attach spring scale to rim of steering wheel, measure pull required to turn wheel. Pull tangent to rim of wheel should be 6-10 ozs. To adjust shaft bearing, loosen lock nut, turn bearing adjuster clockwise to increase drag and counterclockwise to decrease it. Tighten lock nut, recheck adjustment. Then tighten jacket bracket-to-instrument panel bolts, recheck adjustment to be sure bind was not imposed.

Worm & Roller Mesh (Backlash): Turn steering wheel gently through entire range of travel, carefully counting number of turns. Turn wheel back exactly half way to center position. Turn adjusting screw clockwise to take all lash in gear teeth, tighten locknut. Check pull at wheel with spring scale. Pull tangent to rim of wheel should be 14-30 ozs. If necessary, readjust screw to get proper pull.

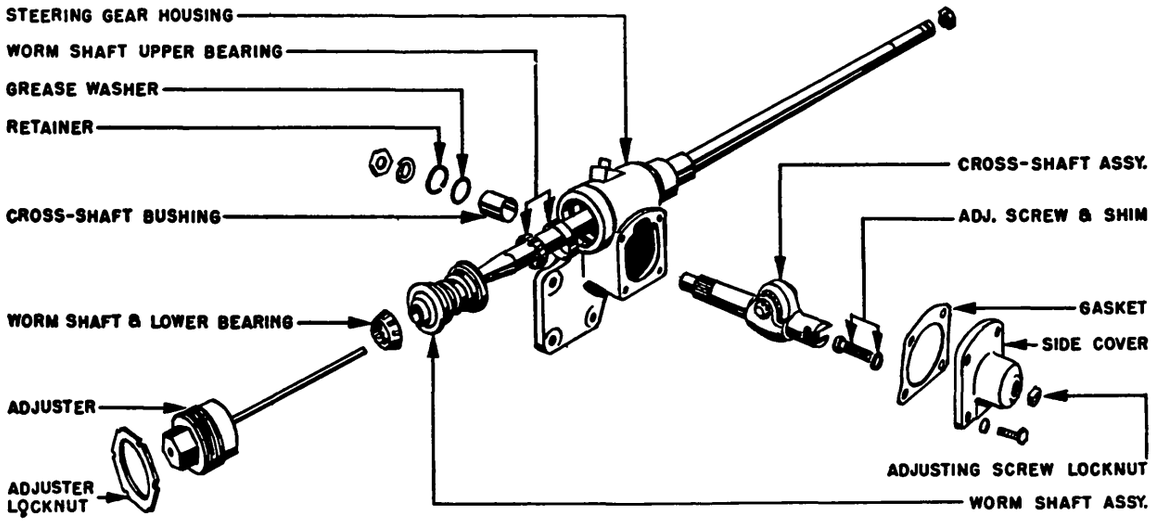
STEERING WHEEL POSITION: Steering wheel center spoke (3 spoke type) should point straight down, or spokes should be horizontal (2 spoke type) with steering gear in straight-ahead position and on center high point.

STEERING WHEEL & HORN RING OR BUTTON REMOVAL:

1952-55 Champion (Custom & Deluxe): Removal—Remove horn button or ring by holding steering wheel stationary and turning button or ring 1/3 turn. Remove steering wheel nut, install puller J-5473, remove steering wheel.

1953-55 Champion, Commander (Regal), President Models: Removal—Pry horn button out of wheel, remove three screws in horn ring, remove ring and sponge rubber pad. Remove steering wheel nut. Install adapter in end of steering post, install puller J-5473, remove steering wheel.

Installation (All 1953-55): Align mark on steering wheel hub and mark on end of steering shaft, install wheel. Tighten retaining nut to 23-27 ft. lbs.



STEERING GEAR REMOVAL & INSTALLATION: Removal (1952-54)—Remove horn button assembly and steering wheel. Disconnect and remove battery, disconnect quadrant light cable and starter cut-out switch cables if equipped with Automatic Drive. Disconnect shift lever rod or rods, loosen jacket clamp bolt. Remove jacket bracket retaining bolts from instrument panel, loosen jacket bracket clamp screw and turn bracket to avoid hitting instrument panel when removing jacket. Slip steering jacket off steering post as an assembly into inside of car. Remove front seat cushion. Disconnect reach rod from pitman arm, remove steering gear housing-to-frame bolts. Tip upper end of steering post down, then remove steering gear assembly from engine side of cowl. Wrap cloth around top of housing to prevent spilling of lubricant. Lift housing end of assembly up and remove from chassis.

Installation—To install, reverse removal procedure.

Removal (1955)—Disconnect battery and disconnect horn switch wire at connector. On Commander & President models, also disconnect battery cable at starter switch. On Commander and President Convertible (Hardtop) and Coupe models, remove battery and battery box. Remove steering wheel and steering post jacket assembly. *(NOTE*—Steering gear housing, steering post jacket, and steering wheel can be removed as an assembly. However, on Commander & President Convertible (Hardtop) and Coupe models, it will be necessary to remove left front engine support cushion and raise left front corner of engine approximately 2"). Remove pitman arm using puller J-5664, then remove steering gear housing-to-frame bolts and remove steering gear through hole in dash and into car.

Installation—To install, reverse removal procedure.

OVERHAUL (STEERING GEAR ASSEMBLY): Disassembly—Remove pitman arm retaining nut and lockwasher from cross-shaft. Punch locating marks on pitman arm and end of crossshaft, remove pitman arm. Remove adjusting screw locknut, then turn adjusting screw out one or two turns thereby relieving bushings and bearing of loads. Remove four side cover retaining screws and lockwashers, pull side cover and cross-shaft assembly from housing. If there is interference between housing and cross-shaft roller, turn cross-shaft slightly so that roller wil clear housing. Remove cross-shaft assembly from side cover by screwing adjusting screw through cover. Slide adjusting screw out of slot in end of cross-shaft, remove shim from adjusting screw. Remove worm shaft bearing adjuster assembly and worm shaft lower bearing. Mark directional signal cam and worm shaft for reassembly. Loosen two set screws which hold directional signal cam to upper end of worm shaft, remove cam. Pull worm shaft out of housing, remove worm shaft upper bearing. Pry grease washer retainer out of housing, remove grease washer. With arbor press, press cross-shaft bushing out of housing.

SAGINAW (STUDEBAKER) WORM & ROLLER STEERING GEAR

Reassembly: With arbor, press cross-shaft bushing into housing until outer end of bushing is 1/32" below shoulder of housing bore. Install upper bearing cup with hard wood block or lead mallet (avoid tilting in bore), bottom cup against shoulder of bore. Soak new grease washer in engine oil, install it in new retainer, then press retainer and washer into housing until retainer bottoms on shoulder of bore. Place worm shaft upper bearing on worm shaft, slide worm shaft assembly into housing. Upper and lower bearings are interchangeable when new, old bearings should not be interchanged. Install worm shaft lower bearings and bearing adjuster assembly. Adjust bearings so there is no end play. Install bearing adjuster lock nut. Place adjusting screw shim on adjusting screw, slide head of screw into slot in end of cross-shaft. Check clearance between head of screw and bottom of slot. Clearance should not exceed .002". If clearance too great, add next thickest shim (available in sizes .063", .065", .067", .069"). When clearance adjusted, start crossshaft into cover. Insert screwdriver through adjusting screw hole in side cover, screw adjusting screw through side cover as far as cross-shaft will go. Place new gasket on side cover, assemble cross-shaft and side cover to housing. Make sure there is clearance between worm and roller, install and tighten side cover retaining screw and lockwashers. Adjust cross-shaft so there is no clearance between roller and worm when roller on high spot, install adjusting screw locknut. Install pitman arm on cross shaft (marks aligned). Install pitman arm retaining nut and lockwasher, tighten nut to 90-100 ft. lbs. torque. Install directional signal cam on upper end of worm shaft (marks aligned), tighten set screws.

STEERING LINKAGE: *See "Steering Linkage"*

Oldsmobile (1954-60)
Pontiac (1955-60)
Rambler, Exc. American (1958-60)
Valiant (1960)

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 BUICK STEERING COLUMN RATTLE CORRECTION:* Effective May 1954 production, a new anti-rattle spring, Part No. 561362, is being installed to eliminate shift tube rattles in steering column. This new, heavier spring, may be installed on earlier 1954 cars where these shift tube rattles have been noted.

►*1955 BUICK STEERING COLUMN RATTLES (Caused By Shift Control Linkage):* An anti-rattle spring, Part No. 1169208 has been released for service to eliminate this condition. To install spring, remove steering wheel and horn ring. Loosen directional signal wiring at lower steering column and remove switch and housing. Remove three bolts from mast jacket to control lever housing support. Place control lever in "Park" position and remove control lever. Remove support and install spring with large end of spring around control lever housing and small end of spring hooked around edge of mast jacket. *NOTE*–On some cars it may be necessary to remove die flash on control lever housing in order to install spring.

►*1955 OLDSMOBILE STEERING COLUMN RATTLE CORRECTION*–Check steering column upper bushing for looseness. Make sure that the three upper bearing retainer screws are tight before replacing bushing.

►*1956 MERCURY STEERING GEAR RATTLE CORRECTION:* May be caused by low lubricant level. Turn wheels to full left position and check lubricant, add lubricant and turn wheels to full right, then back to center. Recheck level to make sure it is up to proper level. If there is still a rattle, check steering sector adjustment, steering linkage & idler arm, ball nut preload or for play between sector shaft and sector adjusting screw.

►*1958 BUICK STEERING WHEEL QUIVER CORRECTION:* Caused by loose lower steering mast jacket clamp bolts. To correct, tighten bolts securely.

►*1958 CADILLAC STEERING COLUMN VIBRATION CORRECTION:* Caused by one or more of following items: Upper and lower steering column-to-toe board clamp bolts loose, or loose bolts at support bracket to firewall (All clamp bolts must be tightened securely after aligning steering column). Steering column to gear misalignment or flexible coupling grounding between shafts or flanges. There must be clearance between upper shaft flange and stop pins (reposition upper flange on column shaft if necessary).

►*1958 CHEVROLET TORQUE SPECIFICATION CAUTION:* Tighten lower coupling clamp bolt to 30 ft. lbs. DO NOT overtighten.

►*1958 EDSEL & MERCURY STEERING BIND OR ERRATIC STEERING CORRECTION:* In addition to normal maintenance procedures, make the following diagnosis and corrections for bent steering shafts or misaligned steering gear assemblies:

1) Remove battery ground cable at battery and remove steering wheel (use Tool 3600-AA). Remove upper bearing centering spring and bushing. *NOTE* - With solid type upper bushing, remove turn signal switch and upper bearing assembly.

2) Raise vehicle, and check run-out of steering shaft (by turning front wheels from full right to left positions), then mark maximum run-out point. Run-out should not exceed .250". If excessive, replace steering shaft assembly. If run-out is not excessive, but the shaft is not centered, check the effort required to pull shaft to a centered position. Use a spring scale such as Tool 3600-E and attach it to steering shaft so pull is against high (marked) spot. Pull required to center shaft should not exceed 8 lbs.

3) When pull required to center shaft is more than 8 lbs. realign steering shaft by placing the high (marked) spot at the four positions given below and then making the correction for each position.

(A) Place high (marked) spot at 6 O'clock position (in relation to column), then loosen steering gear mounting bolts. Raise steering gear and tighten bolts and recheck steering shaft run-out.

(B) Place high (marked) spot at 9 O'clock position (in relation to column), then loosen steering gear mounting bolts and add necessary shims (to center shaft) and retighten bolts. Recheck shaft run-out.

(C) Place high (marked) spot at 12 O'clock position (in relation to column), then loosen steering gear mounting bolts and lower steering gear. Retighten bolts and recheck run-out.

(D) Place high (marked) spot at 3 O'clock position (in relation to column), then loosen mounting bolts and remove shims as necessary (to center shaft) and retighten bolts and recheck run-out.

4) Lower vehicle, reverse items in **(1)** above.

►*1958 EDSEL GEAR LUBRICANT LEVEL NOTE:* Use a piece of 14 gauge wire (as dipstick) to measure fluid level (1½" below filler hole) with steering wheel at full right turn. *CAUTION* - Overfilling will force fluid up steering column.

►*1958 EDSEL STEERING SHAFT EXTENSION SLEEVE PRODUCTION CHANGE (San Jose Cars):* Cars with Serial Nos. W8R-705201 and later, have new sleeve installed and are identified by daub of yellow or blue paint.

►*1958 FORD & THUNDERBIRD STEERING COLUMN NOISE CORRECTION:* Caused by carbon brush contacting steering wheel ring. To correct, apply lubricant such as "Lubriplate Part No. B7A-19584-A" at this point.

►*1958 THUNDERBIRD CONNECTING ROD SLEEVE BOLT INTERFERENCE CORRECTION:* Rotate tie rod clamp bolts forward of tie rod and in vertical position.

►*1958 FORD STEERING GEAR LUBRICANT LEVEL & CAUTION:* To check level, remove filler plug and lower bolt from housing cover. Turn steering wheel to left (to move ball nut below hole) and fill gear with lubricant Part No. B8A-19578-A, until lubricant comes out lower bolt hole. DO NOT use "Multi-purpose" gear lubricant in 1958 type steering gears. Install plug and bolt. Tighten lower bolt to 12-20 ft. lbs.

►*1958 PONTIAC TIE ROD BOLT INSTALLATION NOTE:* To eliminate interference, the tie rod adjuster sleeve bolts must be positioned so center line of bolt will be at 45° angle from horizontal with nuts in up position. It is unnecessary to have clamp ends aligned with slots. in sleeve as in past models.

►*1958 RAMBLER (5810) STEERING LINKAGE PRODUCTION CHANGE (To Eliminate Road Shock):* Linkage change made starting with Serial No. D-420633 (except Serial Nos. D-423300 to D-423789), to provide spring load on pitman arm ball stud seat. To correct road shock on earlier cars, install Kit, Part No. 3209508, consisting of Spring Retainer Clip No. 3200889, Spring No. 3200890, and Spacer No. 3200891. The new spacer is 3/64" shorter. The cup replaces washer and accomodates the additional spring. Assemble new items, tighten end plug to 40-45 ft. lbs. and back off 1½ turns plus 1/8 minus 0. Tighten plug at idler arm to 40-45 ft. lbs. and back off at least 1/8 to 3/8 turns maximum. *NOTE* - In production, retaining cup not used, original washer is relocated in tube, spring is not used, new springs are alike, and spacer is 2-11/16" long.

►*1959 EDSEL STEERING GEAR BALL NUT REPAIR KIT:* A new kit, Part No. MJK-3647-A, containing 60 .281" diameter balls is available for repair of steering gears on 1958-59 Edsel models.

►*1959 FORD STEERING GEAR SECTOR SHAFT COVER BUSHING PRODUCTION CHANGE:* The sector shaft cover bushing has been eliminated from the cover assembly.

►*1959 MERCURY STEERING WHEEL SHAKE & STEERING SHAFT RATTLE CORRECTION:* Check thrust loading spring, located between flange of steering assembly and steering shaft flange and insulator, for proper thrust load as follows: Loosen setscrew on flange and insulator assembly, then move insulator down against force of thrust loading spring by prying on upper flange. *NOTE - This will preload steering shaft bearing, eliminating looseness.* While prying downward, tighten setscrew. *CAUTION - Flange and insulator assembly should be moved just enough so that deformation of steering shaft flange assembly is held to a minimum.*

►*1959 MERCURY STEERING SHAFT BEARING PRELOAD ADJUSTMENT CHANGE:* The worm preload (steering shaft bearing) and total center preload (pitman shaft endplay), have been changed. *See "Adjustment" below.*

►*1960 CORVAIR STEERING SHAFT-STEERING GEAR COUPLING BOLT CAUTION:* This coupling is clamped together by two special bolts, Part No. 6256938. These bolts have a special bearing surface for the portion that is in the coupling. DO NOT use standard bolts for this application because of the safety factor involved.

CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT (C ntinu d)

►*1960 MERCURY STEERING GEAR LUBRICATION (CHECKING & FILLING) PROCEDURE CHANGE.* Turn steering wheel to full left turn position and remove filler plug and the lower sector cover attaching bolt from steering gear housing Agitate lubricant with a screwdriver through filler plug opening. **Fluid level should be even with edge of lower sector cover attaching bolt hole.** When filling steering gear, leave sector cover bolt out to provide an air bleed. Cycle gear through a full right turn and back to full left turn position and recheck fluid level Install cover bolt and filler plug

DESCRIPTION: Recirculating ball nut type Nut mounted on worm and driven through steel balls which circulate in helical grooves in both worm and nut Return guides attached to nut serve to recirculate the two sets of balls through grooves Gear teeth on nut mesh with sector teeth on cross-shaft so that cross-shaft (and steering gear pitman arm) rotate as steering wheel is turned causing nut to move up and down

ADJUSTMENT

ADJUSTMENT: Adjust in following sequence.

►*1959 FORD F-500 & F-600 TRUCK ADJUSTMENT*

NOTE Adjustment procedures are the same as for other steering gears except that worm shaft endplay and preload are controlled by a shim pack between steering gear housing and bearing end plate An adjustment screw, located on top of housing is provided to add side support to the ball-rack After adjusting worm preload and sector mesh, loosen adjusting screw locknut and turn screw until it just touches the ball-rack, then back screw off 1/8-1/4 turn Tighten the locknut

St ring Gear Alignment: Before any adjustments are made to steering gear check for binding at frame bracket mounting bolts and at instrument panel bracket Note clearance between steering gear and frame or bracket. If clearance exists loosen mounting bolts to permit steering gear to shift on frame to align with column bracket, or shim bracket.

St ring Gear Shaft Bearing Preload Adjustment (All Models): With relay rod disconnected from pitman arm and pitman arm properly tightened on steering gear pitman shaft, loosen pitman shaft adjusting screw to obtain a slight backlash between ball nut and pitman shaft Loosen worm thrust bearing adjuster locknut (located at upper end of worm shaft on Ford, Edsel, Mercury & Valiant and at lower end of worm shaft on all other models) and turn adjuster until a slight load is felt (with steering wheel at extreme right or left positions), then tighten locknut Install a spring scale at right angles to spoke or install an inch-pound torque wrench *(see "Worm Bearing Setting" table below for th prop r m thod to us in ch cking pr load)* Note spring scale or torque wrench reading required to keep steering wheel moving (when off high point) Rotate adjusting nut as necessary to obtain correct reading on spring scale or torque wrench (see table below)

Pitman Shaft Endplay Adjustment: With bearing preload adjustment completed (see above), check effort required to pull steering wheel through center (high point) of gear If turning effort is not within specifications (see below), turn pinion shaft adjusting screw clockwise to increase turning effort and counterclockwise to decrease turning effort With locknut tightened, recheck turning effort and adjust as necessary

►*PITMAN SHAFT ENDPLAY ADJUSTMENT CAUTION: This is a push-pull type adjustment and controls pitman shaft endplay as well as gear mesh*

STEERING WHEEL & HORN BUTTON AND RING REMOVAL & INSTALLATION

NOTE–Proceed as follows for each model Reverse removal procedure for installation except as noted

Buick 1954:

Horn Button Removal (Solid Spoke Wheel) - Pry button carefully out of wheel, then remove other horn button parts by removing the three attaching screws and insulator spacer bushings

Horn Button Removal (Flexible Spoke Wheel) - Insert a small screwdriver in notch in cap base and pry against bezel Remove operating ring and wheel base assembly by removing the three screws attaching wheel base to steering hub

Steering Wheel Removal - With horn button assembly removed, back off steering shaft nut several turns. Place direction signal switch in "off" position, then install Puller J-1566 and pull wheel back to nut

WORM BEARING SETTING TABLE

Car Model	Worm Bearing Setting
Buick (1954-56)	①7/8-1 1/8 lbs
Buick (1957-58)	①1/2-7/8 lb

Rambler (1959-60)	①1/4-3/4 lb
Valiant (1960)	②2-4 lbs

① - With spring scale installed on steering wheel (at right angles to spoke)
② - Inch-pounds With inch-pound torque wrench on steering wheel nut

Buick 1955-59:

H rn Butt n Rem val (Seri s 40) - Pry cap out with a thin instrument, remove attaching screws, then remove contact cup and insulating spacers.

Horn Button Removal (Other Series) - Pry out monogram, then unscrew and remove adjusting nut, contact plate and spring (with insulators). Remove steering wheel nut and remove operating ring with cushion and contact spacer .

Steering Wheel Removal - With horn assembly removed, back off steering shaft nut several turns. *NOTE - If nut removed, install it and tight n to within s v ral turns of fully tight position.* Install Puller J-3274 and pull wheel back to nut, then remove steering wheel *NOTE - Direction signal must be in " ff" p sition when r moving or installing wheel.*

Buick 1960:

Horn Button Removal - Disconnect wire at horn cable connector on steering column, then remove horn button or push-bars as follows **Standard St ring Wh l** - Pry out cap with a thin bladed tool and pull out contact spring and terminal Remove steering wheel nut and remove contact assembly **D luxe St ring Wh l** - Remove emblem assembly from center of steering wheel by prying in recess at lower edge Remove wing shaped shroud by removing two inner screws from front of wheel and two outer screws from back of wheel Pull horn wire terminal from center of steering shaft

① - With spring scale installed on steering wheel (at right angles to spoke)
② - Inch-pounds With inch-pound torque wrench on steering wheel nut

SAGINAW WORM & NUT (C ntinued)

Steering Wheel Rem val - With horn assembly removed, back off steering shaft nut several turns. *NOTE - If nut previ usly r moved, reinstall nut and tighten to within s v ral turns f fully tightened position.* Install Puller J-3274 and remove wheel.

Cadillac 1954:

H rn Button & H rn Ring Removal—Disconnect horn wire from terminal at lower end of steering column, depress horn button, turn counter-clockwise until locking ears are released, remove button and horn button spring. Remove steering wheel nuts, then remove horn ring retainer, cushion, and horn ring.

St ring Wh l R moval—Remove horn button, then wheel nut. Install Puller J-1859 and remove wheel.

Chevrolet Pass. Cars 1955-56:

Horn Button R moval - Pry off horn button or ornamental cap and remove horn parts.

Steering Wheel R m val - Remove horn assembly parts, then remove nut from end of steering shaft. Use Puller J-2927-A to remove steering wheel.

Ch vr let Pass. Cars 1957-60):

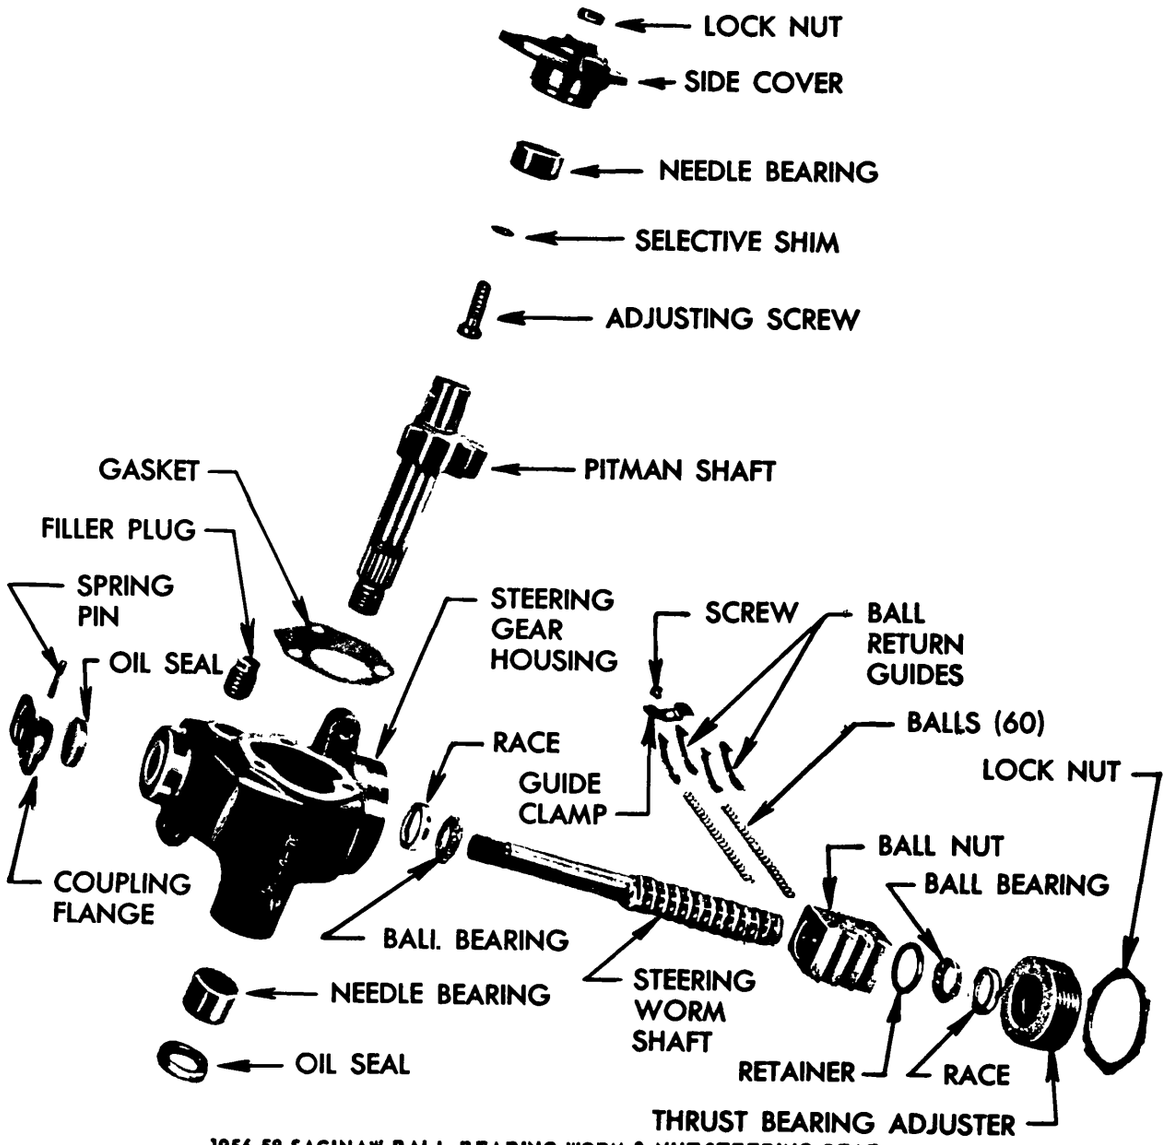
H rn Button Rem val - Remove one screw from underside of each steering wheel spoke and remove ornament. Horn mechanism can then be removed.

St ring Wheel R m val - With horn assembly parts removed, remove steering shaft nut and pull steering wheel from shaft with Puller J-2927-A. Remove spacer from end of shaft.

Chevrolet Trucks 1954-60:

H rn Butt n R m val - Insert a thin instrument between horn button and wheel and pry button out. If wheel has an ornament, remove one screw from underside of each spoke and remove ornament. Remove horn assembly mechanism.

St ring Wheel Removal - Same as for passenger car above.



C m t & Falc n 1960:

H rn Button R moval - Disconnect horn wire under instrument panel at left side of steering column, then press down on horn button or ring and turn counter-clockwise until it lifts out of steering wheel. Remove horn button and spring, then remove steering wheel (see below). Remove turn indicator lever and indicator mechanism retaining screws, and lift mechanism to one side. Remove screws retaining horn button contact and pull wire and contact from steering column.

St ring Wh l R m val - Remove horn button or ring (see above), then remove steering wheel nut and pull wheel from shaft with Puller 3600-AA or 3826 (Comet), 3600-N (Falcon).

Edsel 1958:

H rn Button R m val - On conventional cars, use a thin bladed tool to pry emblem out of steering wheel hub and remove steering wheel (see below). Remove horn ring assembly, spring, contact plate and insulator. On Push-button Shift models, unsnap medallion from center of trim plate, then remove trim plate. Pull off pushbuttons, remove horn ring screws and lift off ring. Remove three horn contact and steering wheel retaining nuts, then remove plate assembly and steering wheel.

1956-58 SAGINAW BALL BEARING WORM & NUT STEERING GEAR (EXCEPT FORD, EDSEL, MERCURY)

Steering Wheel Removal - On conventional models, pry emblem out of steering wheel hub, then remove steering wheel nut and install Puller 3600-AA. Place wheels in straight ahead position and remove steering wheel. On Push-button Shift models, remove horn assembly and remove steering wheel.

Edsel 1959-60:

H rn Button Removal - Disconnect horn wire at bullet connector under instrument panel, then remove horn ring by pressing down on ring and turning it counterclockwise until it lifts out. Remove direction signal control lever, then remove wiring cover which is clipped on left side of steering column. Remove contact plate, "C" washer and coil spring from turn signal switch plate, then remove switch plate with spring washer. Remove two screws at bottom of steering column upper flange and lift turn signal switch and bracket assembly up slightly. Push out horn contact plate and grommet from switch bracket, then remove contact plate and wiring assembly.

CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT
(C ntinu d)

Steering Wheel Removal - With horn ring and contact assembly removed (see above), remove wheel with Puller 3600-AA.

F rd 1958-60:

Horn Button Removal - Disconnect horn wire at bullet connector under instrument panel, then push down on horn ring assembly and turn it counterclockwise until it lifts out. *NOTE - On 1960 models (except Fairlane) remove two screws from underside of steering wheel and remove horn ring.* Remove horn ring spring and horn ring contact brush, then remove steering wheel (see below). Remove wire cover on left side of steering column, then remove two contact retaining screws and remove contact and wire assembly.

Steering Wheel Removal - With horn ring, spring and horn contact brush removed (see above), remove steering wheel with Puller 3600-N.

F rd Thunderbird 1958-60:

Horn Button Removal - Remove steering wheel (see below), then remove turn indicator cam and contact ring. Remove three retaining screws and remove horn contact assembly.

Steering Wheel Removal - Remove steering wheel hub cover and remove steering wheel nut. Use Puller 3600-N to remove wheel from shaft.

F rd Trucks 1959:

Horn Button Removal - Disconnect horn wire at bullet connector below steering gear housing (under instrument panel on Tilt Cab models), then remove horn button by pressing it down and turning it counterclockwise. Remove horn button spring, button contact, and index spring.

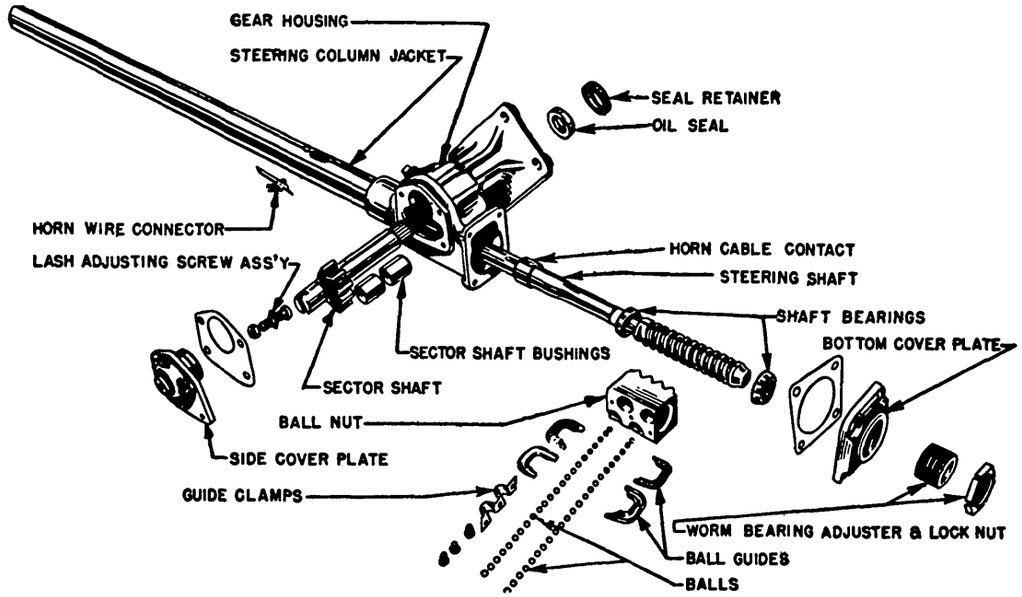
Steering Wheel Removal - Remove horn button assembly (see above), then remove steering wheel nut and index spring support, then install Puller 3600-N and remove wheel.

Mercury 1956-60:

Horn Button Removal - Remove cap and emblem assembly from steering gear hub, then remove steering wheel (see below). Remove turn signal indicator cam from wheel hub and remove snap ring. Remove four screws securing control plate and insulator to horn ring. *Horn control components can now be removed.*

Steering Wheel Removal - With cap and emblem assembly removed from steering wheel hub, remove steering wheel nut and pull wheel from shaft with Puller 3600-AA.

Oldsmobile, All Series 1954-56: Disconnect horn wire at relay, then proceed as follows:



Horn Button Removal (Std.)–Insert sharp instrument underneath edge of horn button, pry button upward and out. Remove steering wheel nut, then contact assembly.

Horn Ring Removal (DeLuxe)–Two spring clips on ends of horn button engage horn ring hub. To remove horn button use small screwdriver to relieve spring tension on one end, lift button from seat. Remove wheel nut, then contact plate, horn ring.

Steering Wh el Removal–Install puller J-1262, remove steering wheel.

Oldsm bile, All Series 1957-58:

H rn Button Rem val (Std.) - Disconnect horn wire at relay, then insert a sharp instrument under edge of cap and pry upward. Remove steering wheel nut and remove horn contact assembly.

1954-55 SAGINAW BALL BEARING WORM & NUT STEERING GEAR

Horn Button Removal (1957 Deluxe) - Disconnect horn wire at relay, then remove screw from undersize of cap. Remove steering wheel nut and remove horn contact assembly.

Horn Button Removal (1958 Deluxe) - Pry cap from shroud with a sharp instrument, then remove screw attaching horn contact retainer to steering wheel hub and carefully pull retainer assembly away from hub until contact assembly can be removed.

Oldsmobile, All Series 1959-60:

Horn Button Removal - Disconnect horn wire from harness. On standard type wheel, remove cap-to-steering wheel attaching screw and lockwasher, then pull cap from wheel. Disconnect horn switch wire from contact assembly. On deluxe wheel, remove setscrew if present, then pry cap and emblem assembly from shroud. On all models, remove steering wheel (see below). On deluxe wheel, disconnect horn switch wires from contact assembly lead, then remove the four shroud attaching screws and shroud. Remove staking from wheel hub and remove contact assembly from steering wheel.

Steering Wheel Removal - With cap and emblem removed, remove steering wheel nut, then pull wheel with Tool 61-9.

Pontiac 1955-56:

Horn Button Removal - Remove deluxe horn ring by turning counterclockwise. On standard wheel, press down on one side of horn button and pry button out from opposite side. Remove steering wheel locknut and nut, washer, horn ring, horn insulator and contact assembly.

P ntiac 1957:

H rn Button R m val - Remove deluxe horn ring by removing four screws retaining covers to bottom of horn ring, then remove horn ring side plates, horn ring, horn ring adapter bushing screws and associated parts. Remove standard button by pressing down on one side and prying button out from opposite side.

Pontiac 1958-59:

Horn Button Removal - Remove deluxe steering wheel ornament by prying up on end. On standard wheel, press down on one side of horn button and pry button out from opposite side. Remove two nuts and washers from plate, then remove plate and insulator. Remove horn ring, upper contact, spring and washer, then remove three screws and insulators from lower contact and support and remove these parts.

Pontiac 1960:

Horn Button Removal - Twist steering wheel ornament to remove, then remove two nuts and washers from shaft and remove spacer bushing screws and bushing. Remove horn ring, pivot ring, spring, insulator and contact plate, contact assembly and insulator.

Pontiac 1955-60:

Steering Wheel Removal - Remove horn button assembly, then remove steering wheel nut (if not previously removed) and pull wheel with Puller J-3044.

Rambler 1958-60:

Steering Wheel & Horn Butt n R moval - Remove horn ring or button and pull wheel from shaft with Tool J-5290.

Valiant 1960:

Horn Button Removal - Disconnect negative ground cable from battery, then rotate horn button ¼ turn counterclockwise and remove button. Remove three screws and bushings from horn button base and remove horn ring. Disconnect wire from horn switch and remove base or switch.

CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT (C ntinued)

St ring Wheel R moval - Remove steering wheel nut and pull wheel from shaft with Tool C-612

STEERING GEAR REMOVAL & INSTALLATION

►*STEERING GEAR INSTALLATION NOTE: To install st ering g ar ass mbly, reverse removal procedures,*

Buick 1954-56 (R m val): Disconnect transmission shift rod from control shaft lower lever & selector lever (synchro-mesh only), then loosen bolt in clamp which secures column jacket to short tube in gear housing Disconnect and remove horn cable connection from steering column jacket Move front seat all the way back and cover seat and back Cover steering column jacket with masking tape. Remove steering wheel and the upper bearing spring and spring seat Cover horn contact and threaded end of steering shaft with masking tape. Remove signal switch and transmission shift control levers. Disconnect wires from neutral safety switch and disconnect wires (signal) from fuse block Detach rubber insulator retainer from dash mat and pull it a foot up on column jacket. Remove jute column pad. Measure and record vertical distance between column jacket and lower surface of instrument panel so column can be reinstalled in same position. This dimension affects steering wheel height, which may have been changed from normal height to suit driver of car. Remove bolts holding cap to steering column bracket, disconnect bracket from instrument panel, then pull upward on column jacket to free it from steering gear Remove starter splash pan from car frame. Remove steering gear-to-frame lower bolts and clamps, then loosen upper bolts enough so that gear can be tilted sideways to provide room for pitman arm puller Remove nut and lockwasher, then remove pitman arm from pitman shaft, using suitable puller With another man inside car to guide steering column and prevent damage to column jacket and front seat, carefully lift steering gear assembly up and forward out of engine compartment, leaving column jacket assembly in body.

Buick 1957-60 (R moval): Mark upper and lower steering gear shaft flanges for correct reassembly, then disconnect flexible coupling Raise car and remove pitman arm Remove three steering gear-to-frame bolts at outside of left frame side rail and remove steering gear from under car

Cadillac 1954 (R m val): Raise front of car, then remove steering wheel and anti-rattle spring under wheel Remove upper and lower column covers, then remove horn wire from terminal at lower end of column Loosen clamp holding lower steering jacket to upper jacket Tap clamp down over lower jacket Disconnect pitman arm from drag link and remove bolts holding gear to frame side rail Remove and save any shims found at upper housing mounting bolts Strike housing with a lead hammer to drive lower steering column jacket down out of upper jacket, then remove gear, lower jacket and steering column from below car

Chevrolet Pass. Car 1955-57 (Rem val): Disconnect all electrical connections and remove back-up light switch (when installed), from mast jacket *(NOTE* - A combination Neutral Safety & Back-up Light Switch is used on Powerglide models) Remove two rubber cover fasteners from inside of dash panel at mast jacket opening Pry off horn button and remove steering wheel Slide rubber seal away from covers, and remove lower cover retaining screw and washer and lower and upper covers. On Auto. Trans. models only, disconnect ends of indicator rod from indicator lever and shifter tube and remove rod Remove neutral safety switch, and remove transmission control selector plate from lower end of steering column On all models, remove clamp bolt from dash panel attaching bracket Disconnect transmission control linkage from shift levers at swivels and remove swivels Remove clamp and rubber shims from bottom of instrument panel From inside car, pull mast jacket assembly off steering shaft, rotating as necessary to clear dash clamp Work shift levers through seal by stretching seal to clear levers Remove pitman arm from sector shaft using Puller J-5504 (see Puller J-5504 Rework for use on Early Cars, below) On Power Steering models, remove the generator-to-support and generator brace bolts and move generator and pump assembly out of position (without disconnecting hoses) to obtain clearance to remove steering gear assembly Remove nuts and lockwashers from steering gear to frame bolts, shims (where installed), and steering gear Remove the four felt seals from mainshaft of steering gear assembly

Chevrolet Pass. Car 1958 (Removal): Place car on hoist or jackstand and remove pitman arm with Tool J-6632 or J-5504. Remove seven front splash pan attaching bolts and remove pan, then remove nuts and bolts attaching steering gear to frame. *CAUTION - Note number and location of any shims found between gear and frame.* Remove coupling clamp bolt between upper and lower shafts and remove steering gear from car.

►**Puller Tool J-5504 Rework (For use on Early Cars):** Grind off 5/16" lip of tool to permit installation between pitman arm and gear housing

Installation—Reverse the removal procedure and note "Steering Wheel Position" and "Steering Gear Alignment" above

Chevrolet Pass. Car 1959-60 (Removal): Place car on jacks and remove pitman arm (Tool J-6632 or J-5504) Remove splash pan, then remove steering gear-to-frame bolts and shims Remove coupling clamp bolts and withdraw steering gear and shaft from under car To install, reverse removal procedure being sure to have mark on worm shaft aligned with slot of coupling clamp (with steering wheel in normal straight ahead position)

►*CHEVROLET LOWER COUPLING REPLACEMENT NOTE:* If lower coupling is to be removed, it will be necessary to either lower the steering gear from its original position, or the mast jacket, upper steering gear shaft, coupling and intermediate shaft must be loosened and pulled up far enough to permit coupling to be removed from worm shaft.

Chevrolet Trucks 1954-59 (Conventional Models): Removal-

1. Disconnect horn wire remove wire retainer from steering mast jacket Remove horn button and steering wheel, then remove steering mast jacket-to-instrument panel bolts, bracket and grommet

2 On ½ and ¾ ton trucks disconnect gearshift upper control shaft support from mast jacket, then separate upper steering control shaft from lower shaft by removing lower bolt from both shaft clamps.

3. Remove sheet metal screws attaching steering mast jacket toe-board grommet and seal to toe-board plate. Slide toe-board grommet and seal up mast jacket, remove toe-board plate

4. On Forward Control models, hoist front end of vehicle, remove mast jacket opening cover

5. On ½ and ¾ ton trucks, remove bolts and clamp attaching gearshift control housing to steering column mast jacket

6. Disconnect pitman arm, using puller J-1025, then

7. On Forward Control models, remove steering gear by moving forward, down and out of vehicle. On 1957-58 3100 Series, V8 engine models, remove exhaust crossover pipe.

8. On models other than Forward Control, from inside cab remove three bolts attaching rear of left front fender skirt to toe-board, remove six bolts attaching fender skirt to fender ledge, then remove fender-to-dash brace rod, disconnect horn wire

9. Working under fender pry rear of fender skirt forward and outward until it rests on outside toeboard flange, then, working over fender, pry fender skirt outward along frame at steering gear housing to provide proper clearance between frame and opening in fender skirt

10. Slide steering gear assembly slightly upward toward toe-board, then rotate until attaching flange is up Raise slightly and slide forward, removing assembly over front of front fender

Chevrolet Trucks 1955-59 (Cab-Over-Engine & Low Cab Forward Models): Removal -

1. Remove steering wheel and disconnect dash mounting bracket Remove left hand floor pan and steering column grommet Disconnect horn wire Remove fender skirt bolts and remove skirt

2. Remove pitman arm using Tool J-1025, and remove steering gear to frame mounting bolts

3. Move gear back to clear radiator grille side baffle assembly It will then be possible to drop gear down through fender skirt opening, pulling the steering column through opening in floor

Chevrolet Trucks 1960 (All Models): Removal - Loosen bolt attaching lower end of intermediate shaft to steering gear, then disconnect pitman arm from steering shaft, using Puller J-6632 Remove all steering gear-to-frame mounting bolts and remove steering gear

Comet & Falcon 1960: Removal - Raise front of car and place on stands, then remove pitman arm from sector shaft Remove steering gear bolts from underbody and disconnect transmission shift rods at shift levers Pull rubber seal up on steering column and fold mat aside Move dash panel insulation out of way, then remove retaining screws from steering column weather seal on dash panel and remove column cover plates and gasket Remove steering wheel (see above) On automatic transmission cars, remove neutral switch wires Remove upper bearing sleeve and spring, then remove turn indicator lever Remove steering column clamp-to-instrument panel bolts and remove clamp (upper and lower halves) and remove insulator Slide steering col-

CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT (C ntinu d)

umn tube assembly from steering shaft, guiding shift levers up through rubber seal at dash panel. Remove steering gear and shaft assembly out toward front through engine compartment.

Corvair 1960: Removal - Remove pitman arm with Tool J-6627, then disconnect coupling, remove gear attaching bolts, and remove gear by sliding it forward and down.

Edsel 1958 (Removal): Stub Shaft Gear Type - Disconnect direction signal wires from connectors under instrument panel to left of steering column. Remove terminal block from lower side of steering column tube. Remove steering column upper bracket cap and move column and wheel assembly upward and rearward to remove from car. Use Tool 3590-E to remove sector shaft arm, then remove steering gear-to-frame bolts and remove steering gear.

L ng Shaft Type - Remove steering wheel assembly. *See St ering Wheel and Horn Ring Removal above.* Disconnect turn indicator wires under instrument panel and automatic transmission neutral switch wires if so equipped. Slide rubber seal up steering column and fold back floor mat. Disconnect speedometer cable at speedometer and remove clutch pedal release rod, equalizer shaft, bushing and bracket assembly. Remove floor panel cover plate and remove steering column bracket to instrument panel screws. Remove sector shaft arm with Tool 3590-E and disconnect transmission or gear shift rods from levers on steering column. Remove steering gear housing-to-frame bolts and remove steering gear through passenger compartment.

Edsel 1959: Removal - Remove steering wheel *(see "Steering Wheel Removal" above),* then disconnect wires under instrument panel. Remove two screws that fasten steering column bracket to instrument panel, then remove turn indicator lever and gear shift lever from steering column. Remove screws from steering column weather seal on engine compartment wall and fold floor mat away from steering column. Disconnect speedometer cable from instrument panel, then remove right hand cover plate and feed cable through cover plate. Disconnect clutch pedal release rod at clutch pedal, and remove cover plate from rod. Disconnect clutch return spring and disconnect gear shift linkage at steering column bracket. Remove pitman arm retaining nut and remove arm from shaft. Remove steering gear housing bolts from frame side rail and remove steering gear through engine compartment. On cars with automatic transmission, remove selector dial indicator cover and control selector indicator. Disconnect neutral switch wires at bottom of steering column. To install the assembly, reverse removal procedures and note the following: Position pitman arm on shaft so that it points straight forward with steering worm at midpoint of travel, tighten pitman arm nut to 110–150 ft. lbs.

Edsel 1960: Removal - Remove steering wheel *(see "St ring Wheel R m val" above)* and disconnect the turn indicator wires under instrument panel. On automatic transmission cars, remove selector dial indicator cover and selector indicator. Remove two screws attaching steering column to instrument panel. Pull rubber seal up on column and fold mat away from column. Remove retaining screws from steering column weather seal, then disconnect speedometer cable at speedometer, remove steering column cover plates and route cable through weather seal and gasket. Disconnect manual control linkage at steering gear and disconnect clutch equalizer bar. On automatic transmission cars, disconnect neutral switch wires at bottom of steering column. Raise car and remove pitman arm from sector shaft. Remove steering gear housing attaching bolts and remove steering gear through inside of car. Install by reversing removal procedures and note the following: Tighten pitman arm retaining nut to 110-150 ft. lbs. Tighten steering gear housing attaching bolts to 28-43 ft. lbs. Tighten steering column bracket-to-instrument panel screws to 5-7 ft. lbs.

Ford 6 & Y-V8 1958-59: Removal - Remove steering wheel *(see "Steering Wheel Removal" above),* then disconnect the turn indicator wires from under instrument panel and remove steering column-to-instrument panel screws. Remove turn indicator lever and gear shift lever from steering column and fold back floor mat out of the way. Remove retaining screws from steering column weather seal on engine compartment wall and disconnect speedometer cable at instrument panel. Remove right hand cover plate. Disconnect clutch pedal release rod at clutch pedal and remove cover plate from rod. Disconnect clutch return spring and disconnect gear shift linkage at steering column bracket. Remove sector shaft arm retaining nut and remove arm with Tool 3590-AA. Remove steering gear housing bolts from frame side rail and remove steering gear through engine compartment.

Ford 1958-59 (Exc. 6 & Y-V8): Removal - Remove steering wheel. *See "Steering Wheel & Horn Ring Removal" above.* Disconnect turn indicator wires from under instrument panel. On Auto. Trans. cars, remove selector dial indicator cover and control selector indicator. Remove steering column-to-instrument panel screws and pull rubber seal up steering column and fold floor mat out of way. Remove steering column weather seal screws, disconnect speedometer cable at speedometer, and remove steering column opening cover plates and pull cable through weather seal and gasket. Disconnect manual control linkage at steering gear and disconnect clutch equalizer bar. On Auto. Trans. cars, disconnect neutral safety switch wires at bottom of steering column. Place car on jacks and remove sector shaft arm nut and pull arm with Tool 3590-AA. Remove steering gear-to-frame side rail bolts and remove steering gear through insi of car.

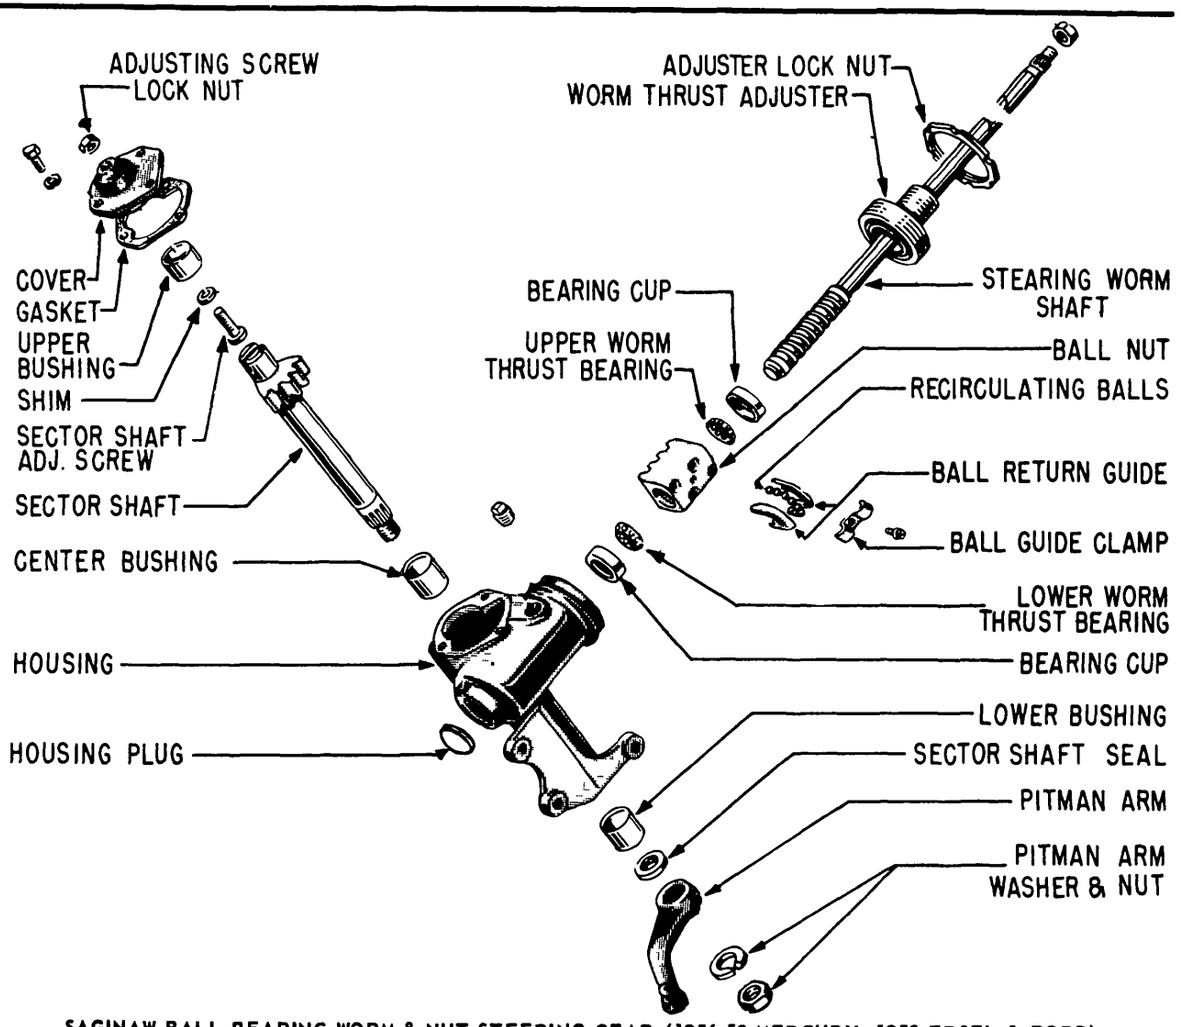
Ford 1960 (S.M. Transmission): Removal - Disconnect clutch pedal release rod at pedal, then disconnect clutch equalizer bar from clutch pedal rod by removing lower adjusting nut and pushing equalizer bar forward. Raise car and disconnect clutch release lever spring and remove release rod. Remove equalizer bracket and equalizer bar. Remove pitman arm, then remove steering gear attaching bolts and lower car to floor. Remove steering wheel (see above), then move steering column grommet up and disconnect speedometer cable at speedometer. Disconnect horn and turn signal wires. Push clutch pedal about halfway to floor, remove bumper bracket, and carefully allow pedal to retract. *CAUTION - Pedal is spring loaded and must b controlled.* Remove steering column tube retaining bolts at instrument panel and remove tube and attaching parts from steering shaft. Remove steering gear through passenger compartment.

F rd 1960 (Aut . Transmission): Removal - Raise the car on a hoist and remove pitman arm from sector shaft, then remove steering gear housing attaching bolts and lower car to floor. Disconnect neutral switch wires at bottom of steering column, and manual control linkage at steering gear. Pull rubber seal up on column and fold floor mat out of way. Remove retaining screws from steering column weather seal, remove cable from speedometer, and remove steering column opening covers. Remove selector dial indicator cover and control selector indicator. Disconnect turn indicator and horn wires under instrument panel and remove steering wheel (see above). Remove two screws fastening steering column-to-instrument panel bracket to instrument panel, then remove steering column tube, neutral switch, and selector lever as an assembly. Remove steering gear through inside of car.

Thunderbird 1958-60: Removal - Remove steering wheel *(see "Steering Wheel Removal" above).* Disconnect parking brake handle and bracket and remove cowl side trim panel and left vent control handle. Disconnect hood lock release cable bracket. On Cruise-O-Matic Cars, remove starter-neutral switch and disconnect horn wire. Disconnect wiring assembly from steering column and remove instrument panel lower panel retaining screws. Move lower panel to one side. Pull steering column cover plate insulation to one side and disconnect parking brake bracket from cover plate. Remove steering column cover plate and parking brake handle, then remove steering column retaining bracket from instrument panel. On Conventional or Overdrive cars, disconnect clutch linkage, as necessary, to provide clearance for gear removal and disconnect gear shift levers near steering column. Raise car and remove sector shaft nut and remove sector shaft arm with Tool 3600-N. Remove steering gear attaching bolts from underbody and remove gear through inside of car.

Ford Trucks 1959 (Exc. Tilt Cab M dels): R moval - Disconnect battery, then disconnect horn wire from bullet connector and remove steering wheel. Loosen steering column lower clamp and slide clamp down. Disconnect transmission shift control rods at shift levers (if so equipped). Remove steering column upper bushing spring and bushing, then disconnect turn signal wires, and remove them from retaining clip at instrument panel. Remove steering column bracket clamps and rubber sleeve. If truck has a floor mounted gearshift lever, pull steering column tube off shaft. If truck has a Fordomatic or a remote gearshift lever, remove steering column shields from floor pan. Remove engine oil filter. On a clutch equipped truck, disconnect clutch retracting spring, then remove clutch hydraulic cylinder out of the way. Remove pitman arm, then remove steering gear assembly from under truck (floor mounted gearshift), through cab (Fordomatic or remote type gearshift). If steering column tube not removed, loosen lower clamp and remove tube.

Ford Trucks 1959 (Tilt Cab Mod ls): R moval - Remove horn wire brush from steering column just below instrument panel bracket, then remove upper universal joint retaining nut and bolt. Turn wheels to right and remove pitman arm. Remove steering gear housing from frame



CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT
(C ntinued)

side rail (with universal joint attached). If woodruff key falls out of steering shaft, save it for installation. Remove universal joint from worm shaft.

Mercury 1956 (Rem val): On models with power brakes, remove clamp securing reservoir hose to brake booster cylinder, and to dash panel. Move hoses away from opening in dash panel. On all models, remove steering wheel (see above). Disconnect electrical connection at junction block near lower positi n of steering column and also at backup lamp and neutral safety switches. Remove accelerator pedal from pushrod. On synchro-mesh cars, remove brake and clutch pedals and pull carpet away from dash panel opening. Remove insulator and floor opening cover plates. *NOTE - There are two cover plat attaching capscrews in engine compartment.* Remove screws securing steering column bracket to instrument panel and pedal support bracket. Disconnect shift rods from steering column shift arms. Loosen clamp on lower steering column at gear housing, then remove column tube through inside of car. Raise front of car and remove gearshift linkage splash shield, then remove pitman arm with Tool 3590-AA. Remove bolts securing steering gear housing to frame side rail and remove gear assembly through passenger compartment. *CAUTION - Note location and number of shims found b tween mounting bolts and frame side rail (if any).*

M rcury 1957-58 (R m val): Disconnect battery, raise car and remove sector shaft nut and sector shaft arm, with Tool 3590-E. Remove three steering gear to frame bolts and note position and number of shims at each bolt hole. Remove muffler inlet pipe to exhaust manifold bolts, then lower car and remove air cleaner and air cleaner intake duct. On Conventional & Overdrive cars, remove gear shift arms from rods and push rods to center of car. When back-up light switch is mounted on steering column, disconnect leads at switch and swing leads clear of bottom of power brake booster. Remove back-up light switch and bracket assembly. Disconnect clutch rod and remove exhaust manifold and No. 8 spark plug. Remove steering wheel. *See "Steering Wheel & Horn Ring R moval" ab v .* Disconnect turn signal and horn electrical connections (wires and junction block will hang free). Disengage accelerator pedal from push rod and pivot pedal toward rear. On Conventional & Overdrive Cars, remove clutch pedal and rod assembly, then remove brake pedal assembly. Turn back floor mat to clear area and attaching parts (for right and left column cover plates), remove left plate and slide right plate along speedometer cable. Remove steering column opening seal and remove column bracket cover plate directly above steering column in lower portion of instrument panel, then remove steering column bracket. The steering gear and shaft assembly can now be turned through opening in dash panel. To install, reverse removal procedure, install shims as removed and tighten gear-to-frame bolts to 40-50 ft. lbs., steering wheel nut to 40-50 ft. lbs. Adjust column tube to steering wheel clearance to 1/8". Tighten instrument panel screws to 10-13 ft. lbs. Torque steering gear nut to 120-130 ft. lbs.

SAGINAW BALL BEARING WORM & NUT STEERING GEAR (1956-58 MERCURY, 1958 EDSEL & FORD)

Mercury 1959-60: Removal - Disconnect steering shaft from gear assembly at flexible coupling, then raise car and remove pitman arm with Tool 3590-E. Loosen manifold outlet pipe clamp and loosen hanger at forward end of muffler. Remove muffler outlet pipe. *NOTE - On dual exhaust systems, remove crossover pipe, then remove left hand outlet pipe only.* Remove gear assembly-to-frame bolts and remove gear assembly. To install unit, reverse removal procedure and tighten pitman arm to 110-140 ft. lbs.

Oldsmobile, All Series 1954-59: Removal - Disconnect horn wire at relay and remove steering wheel assembly. Remove floor mat. On 1951-56 models, loosen upper and lower mast jacket cover attaching screws or clamps. On 1957-58 models, remove upper mast jacket clamps and disconnect shift linkage from lower end of mast jacket. On all models, raise car and remove pitman arm and steering gear mounting bolts. On 1951-56 models, drop gear down and pull it out of mast jacket. On 1957-58 models, remove gear and mast jacket assembly by pulling it up through opening in floor.

Oldsmobile, All Series 1959-60: Removal - Remove steering wheel assembly (*see "Steering Wheel & Horn Button Removal" above*). Remove upper bearing spring and seat. Turn back floor mat and remove mast jacket cover plate screws, then remove upper mast jacket clamps. Disconnect shift linkage from lower end of mast jacket. Remove pitman arm with Tool J-5504-B and remove steering gear mounting bolts. Remove gear and mast jacket assembly by pulling it up through opening in floor. Loosen lower clamp and remove mast jacket from gear. To install, reverse removal procedure and

CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT (C ntinu d)

tighten steering gear-to-frame bolts to 50-60 ft. lbs. and pitman arm nut to 90-120 ft. lbs.

P ntiac, All Models 1955-57 (Removal):

1. Remove steering wheel. If car is equipped with power brakes, remove power brake unit. Disconnect direction signal wires at connector under instrument panel. Remove signal lever.
2. Remove steering column lower finish plate and remove steering column and pedal plate, felts, and retainer plate.
3. Disconnect horn wire and neutralizer switch. Remove gearshift lever and disconnect selector rods from levers on steering column.
4. Raise car on hoist and remove engine side apron. Remove pitman arm with Puller J-5504 and remove steering gear housing to frame bolts, leaving the forward bolt in place to support steering gear. Remove steering column lower bracket to upper bracket bolts.
5. Remove remaining steering gear housing to frame attaching bolt and remove steering gear by bringing it through floor board and over steering linkage toward right fender. Save shims found between housing and frame.

P ntiac, All Models 1958 (Removal): Remove steering wheel and disconnect directional signal wiring harness at connector under the instrument panel. Remove the directional signal lever. Remove the steering column and lower finish plate and roll back floor mat and remove steering felt and felt retainer plate. Disconnect horn wire and starter neutral switch wire. Remove gear shift levers, disconnect gearshift selector rods from steering column, remove splash apron, starter motor, turn signal wires, and pitman arm. Remove bolts holding steering column lower bracket to upper bracket on instrument panel and remove steering gear housing-to-frame bolts. Disconnect lower control arm and remove coil or air spring to remove steering gear from front of car. To install, reverse removal procedure and install shims in same locations.

Pontiac 1959: Removal - Remove steering wheel. *See "Steering Wheel & Horn Ring Removal" above.* Remove direction signal wiring harness at connector under instrument panel, then remove direction signal lever. Remove steering column lower finish plate and roll back floor mat, then remove felt and felt retainer plate. Disconnect horn wire and starter neutral safety switch wire. Remove gearshift levers and disconnect selector rods from steering column. Remove splash apron, starter motor, turn signal wires, and pitman arm. Remove bolts holding steering column lower bracket to upper bracket on instrument panel and remove steering gear housing-to-frame bolts. Disconnect lower control arm and remove coil or air spring in order to remove steering gear from front of car. *CAUTION - Retain and note location of shims found between steering gear housing and frame side rail. These must be replaced when steering gear installed.*

Pontiac 1960: Removal - Remove steering wheel. *See "Steering Wheel & Horn Ring Removal" above.* Disconnect direction signal wires at connector under instrument panel and remove direction signal lever. Remove steering column lower finish plate, then roll back floor mat and remove felt and felt retaining plate. Disconnect horn wire and neutral safety switch wire. Disconnect gearshift selector rods from steering column and remove floor pan cover. Remove back-up lamp and switch wires, and turn signal wires. Remove pitman arm, then remove steering gear housing-to-frame bolts and remove steering gear. *CAUTION - Retain shims found between gear housing and frame for installation at same locations.*

Rambler 1958-60: Removal - Disconnect battery and remove steering wheel *(see "Steering Wheel Removal" above).* Remove toe board plate screws and loosen lower-to-upper jacket tube screws. On Series "10" & "20", remove pitman arm with Tool J-5566-03. Support engine at front and remove engine front crossmember, then mark location of turning radius stop plate and remove plate. Remove steering gear housing-to-mounting plate screws and lower gear. On Series 80, remove left wheel, mark position of turning radius stop plate, then remove plate and pitman arm nut, loosen steering gear housing attaching screws and pull pitman arm with Tool J-5566-03. Remove left exhaust manifold. Support engine at front and remove left front engine support mounting bracket. Remove front crossmember with attached stabilizer bar. Remove three steering gear housing screws and lower the steering gear. To install, reverse removal procedure and replace any shims found in removal.

Valiant 1960: Removal - Raise car and remove pitman arm, then remove bolts attaching steering gear to frame. Remove bolt from coupling clamp at upper end of steering worm shaft, then support steering gear and tap coupling assembly upward with a mallet until it is free from shaft splines. Remove steering gear.

STEERING GEAR OVERHAUL

STEERING GEAR OVERHAUL: Disassembly—With steering gear removed, remove the pitman arm with a suitable puller (CAUTION—Do not drive pitman arm from cross shaft as damage to worm and ball nut will result). Loosen adjusting screw lock nut, then remove housing side cover with pitman shaft attached, remove gasket. Separate pitman shaft from side cover by unscrewing the adjusting screw. Loosen lock nut and back off worm thrust bearing adjuster several turns, then remove housing end cover and gasket. Remove lower thrust bearing, steering shaft, and upper bearing from housing. (NOTE—Manufacturer recommends that ball nut NOT be disassembled; however, if it is necessary to disassemble ball nut, proceed as follows): Remove ball return guide clamps and guides from ball nut, turn ball nut over to remove balls (Caution—Hold shaft and ball nut assembly over a wide pan while disassembling to retain all balls. It is very important that balls be counted, and the same number of balls reinstalled when gear is assembled). Remove ball nut from steering shaft.

Reassembly: (Ball Nut)—Place worm shaft flat on bench and slip nut over worm with ball guide holes up and shallow end of rack teeth to left from steering wheel position. Align grooves in worm and nut by sighting through guide holes. Count out one-half the number of balls removed at disassembly, and drop them into one of the guide holes while turning the worm gradually away from the hole, until guide hole is full from bottom of one guide hole to the bottom of the other (in cases where balls are stopped by end of worm, hold down the balls already dropped into hole and rotate worm back and forth). Lay one-half of guide, groove up, on the bench and place remaining half of balls in it. These remaining balls should fill it. Close this half of guide with other half. Hold both halves of guide together and plug each end with vaseline to hold balls in place. Push guide into holes of nut, completing one circuit. Repeat same operation with other circuit. Then assemble ball guide clamp to nut with lockwashers under clamp screws and tighten screws securely.

Steering Gear—Place worm shaft and nut assembly into housing and place upper roller bearing over worm shaft. Place new housing end cover gasket over end of worm shaft, make sure horn wire is through opening in mast jacket, then slide housing end cover over worm shaft and assemble it to housing. Install lower roller bearing, worm bearing adjuster and lock nut in lower end of housing. Assemble lash adjuster with shim in slot in end of sector shaft. Check end clearance which should not be greater than .002". Adjust end clearance with shims as required. Start sector shaft pilot into bushing in side cover. Then, using a screwdriver through hole in cover, turn lash adjuster in counter-clockwise direction to pull sector shaft pilot into its bushing as far as it will go. Rotate worm shaft by hand until ball nut is at center of travel. Place a new gasket on side cover, then push side cover assembly including sector shaft into place. After making sure there is some play between rack and sector teeth, assemble and tighten side cover bolts. Install steering gear in car (see instructions below), and adjust steering gear. See ADJUSTMENTS above.

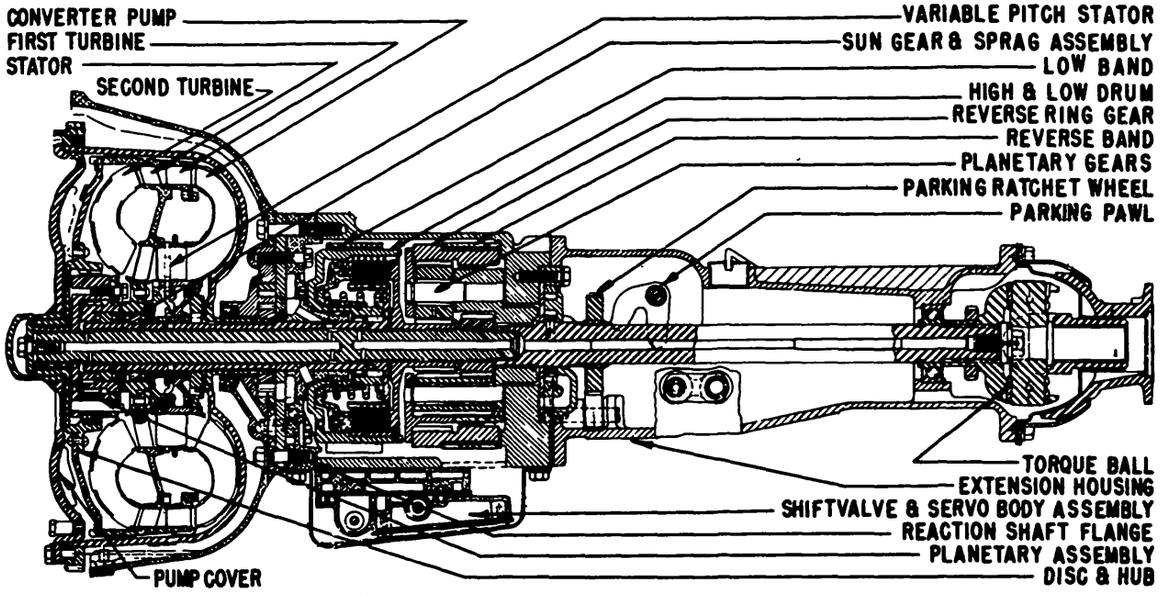
IMPORTANT—Refer to the "Annual Data" for all data on car models later than 1960.

1954-60 BUICK TWIN TURBINE & VARIABLE PITCH DYNAFLOW DRIVE

Buick (1954-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*STARTING ENGINE BY PUSHING CAR:* Place shift control lever in "N" (Neutral) position until car reaches a speed of 15 MPH, then move control lever to "L" (Low) position and continue to increase speed until engine starts at approximately 25 MPH. After engine starts, return lever to "N" (Neutral) position for engine warm-up.



►*TOOL MODIFICATION NOTE (REACTION SHAFT BUSHING INSTALLER TOOL J-5816):* Shoulder of tool must be ground off sufficiently to allow reaction shaft bushing to be driven deep enough so that it is located between the two snap ring grooves inside reaction shaft.

►*1956 TORQUE CONVERTER PUMP PRODUCTION CHANGE & SERVICE CAUTION:* Late 1956 cars will have two types of converter pump assemblies used interchangeably in production. The new converter pump is a steel stamping and is identified by an orange "X" on converter pump and also on top of bellhousing. The earlier conventional aluminum pump will also be used. When removing and replacing torque converter-to-flywheel and cover bolts the square head bolt, Part No. 1171053 must be used with the steel converter pump and the "D" shaped bolt head must be used with the aluminum casting pump. Transmission equipped with the steel torque converter pump will require one more pint of transmission oil than transmissions having the aluminum pump.

►*1956 DYNAFLOW TRANSMISSION OIL LEAKAGE CORRECTION (OIL BLOWING OUT OF BREATHER PIPE):* See *"Overhaul" below.*

►*1956 DYNAFLOW FRONT PUMP SEAL SERVICE REPLACEMENT (NEW TYPE SPRING LOADED CARBON SEAL FOR USE WITH TRANSMISSIONS HAVING ALUMINUM PRIMARY PUMP):* The new carbon seal is designed to seat against flat face of primary pump hub, making it possible to use the seal on pumps which would normally be replaced because of scored hub in area of the present seal. It is suggested the new seal be installed in transmissions having primary pump which would ordinarily be replaced because of sealing difficulties. See *"Overhaul" below, for installation procedures.*

►*1957 (EARLY CARS) STATOR CONTROL VALVE STICKING CORRECTION:* Stator control valve may stick in the down position and allow stator blades to remain in high angle position at all times. If this condition exists, engine speed during part throttle in drive range will be abnormally high and there will be no evidence of increased engine RPM when accelerator is pressed to floor. Adjust stator control linkage (see *"Throttle Linkage Adjustment" in car model page*). If this does not correct the condition, check to see if there is a belleville type washer (dished washer) between valve operating lever and bearing nut. If one is found at this location, remove and discard it, leaving the flat washer. If stator control valve continues to stick, replace the valve assembly with Part No. 1179828. During reassembly of the high accumulator, adjust stator operating rod as follows: With crank against actuating valve and valve in extreme upper position, lever should be tight against stop pin when lock nut is tightened.

BUICK VARIABLE PITCH DYNAFLOW DRIVE (SECTIONAL VIEW)

►*1957 VALVE BODY & VALVE PRODUCTION CHANGE:* The later valve body prevents oil being dumped above the screen as ports in the valve body have been changed. The later valve body is identified by absence of ports in valve boss. Valve is identified by a groove in valve land adjacent to actuating lever end. These parts are interchangeable; however, the adjusting procedure is different when later type valve body is used. See *"Valve & Servo Body Installation" under "Overhaul" below.*

►*1957 (EARLY CARS) TRANSMISSION OIL BYPASSING VALVE BODY SCREEN CORRECTION:* When oil pan is removed, check to see if there are openings between screen frame and valve body at the six corners of frame. If so, install an "O" ring, Part No. 1336936 (front pump "O" ring seal) by loosening oil screen screws and pressing the "O" ring under screen frame at all six corners. Tighten screws. Later type screen has been changed to eliminate the openings.

►*1957 LOOSE SHIFT CONTROL LEVER NOTE:* If the shift lever can be moved from "R" to "P" position without lifting lever, and no definite stops are noticed at any point between these two positions, the stop pin at end of shift lever is worn or broken and the shift lever should be replaced. To install shift lever, proceed as follows: Remove shift lever to housing pin retainer and drive out pin. Pull lever out toward steering wheel and remove lever (*CAUTION - When removing lever, take care to keep lever return spring from flying loose*). Position lever return spring on lever with closed end of spring engaged in groove of lever and open ends of spring pointing downward. Insert a Phillips screwdriver through spring coils and hole in lever, then insert lever into housing. Using needle nosed pliers, rotate each end of return spring into lever housing. When spring is in housing, push lever inward until screwdriver makes contact with housing, then remove screwdriver and push lever in until lever retaining pin can be driven into position. Install pin retainer by rotating it on lever housing to lock it in position.

►*1957 DYNAFLOW OIL PAN BOLT TIGHTENING CHANGE:* To prevent overtightening of oil pan bolts and damage to oil pan gasket, resulting in oil pan leakage, tighten the bolts to 10-12 ft. lbs. This supersedes previous specifications of 15-18 ft. lbs.

►*1957 SHIFT LINKAGE RATTLE CORRECTION:* Install an anti-rattle spring washer, Part No. 1180307, between clevis and control shaft lever at bottom of steering column.

►*1957 DYNAFLOW VALVE BODY PRODUCTION CHANGE & SERVICE NOTE:* To prevent the possibility of air being drawn into the hydraulic system during cornering, the valve body vent hole has been relocated to a position in the rear pump suction passage. Whenever the oil pan is removed on early 1957 cars, the control valve should also be removed and the original 1/8" vent hole should be plugged with a self tapping screw. A new hole should be drilled in the rear oil pump passage. See *"Overhaul" below.*

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

►*1957 DYNAFLOW FRONT PUMP OIL SEAL PRODUCTION CHANGE* A new silicone-rubber seal is being used in production and for service replacement. When installing the new seal, care must be taken to prevent tearing or damage. The retaining spring around sealing element must be in toward pump when installed.

►*1958 STATOR CONTROL VALVE (IN HIGH ACCUMULATOP) REPLACEMENT CAUTION:* When replacing stator control valve in high accumulator; if accumulator is marked "oversize" (stamped on top side next to stator control valve stop), it will be necessary to replace complete accumulator assembly as "oversize" control valve is not available for service replacement.

►*1958 SHIFT CONTROL VALVE STOP (IN VALVE & SERVO BODY) PRODUCTION CHANGE:* On later production transmissions not having a control valve stop pin (located adjacent to "low servo" on valve body), adjust control valve as follows: Move shift lever to "D" (Drive) position and note position of valve. Groove in first land of valve should be flush with boss on valve body. If valve is not properly positioned in valve body, loosen lock and bolt and shift the adjusting lever on valve lower operating lever as required to obtain specified setting. Tighten bolt and nut on levers, making sure that adjustment does not change.

►*1959 DYNAFLOW SECOND TURBINE CARRIER & SUN GEAR PRODUCTION CHANGE & SERVICE REPLACEMENT CAUTION:* Second turbine front thrust washers used with early and later type assemblies are different. If replacement of the thrust washer is necessary, use the same type as removed.

►*1959 DYNAFLOW TURBINE ASSEMBLY PRODUCTION CHANGE:* Beginning with Transmission Code No. W-045, a new turbine assembly consisting of a first turbine, first turbine support, and first stator is being used in production. The new parts are not interchangeable separately with earlier 1959 transmissions but may be used as a complete unit. Service procedures for assembling and disassembling the twin turbine assembly having the new parts is different as indicated below.

►*1959 LOW ACCUMULATOR CHANGE (IMPROPER ASSEMBLY CAN CAUSE HARSH ENGAGEMENT OF LOW BAND): NOTE - The new type accumulator may also be found on some late 1958 models.* Metered oil flow to low servo is provided by the space around the pin in the new type accumulator as compared to the drilled metering orifice in previous accumulators. It is important that the pin be installed, otherwise harsh engagement of the low band will result.

►*1959 DYNAFLOW TRANSMISSION SUPPORT REMOVAL & INSTALLATION CAUTION:* Before any service operation requiring the removal of transmission support is performed, the original location of the support must be marked so it can be reinstalled in exactly the same location and at the same angle. Improperly installed support will cause drive line stress and roughness.

►*1959 DYNAFLOW CASE PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* Later type cases without an expansion plug at the low brake band anchor hole in case require a longer low brake band anchor. When installing a later type case to replace the earlier case, it is necessary that a new anchor, Part No. 1191861, be installed.

►*ACCUMULATOR BODY CAP LEAKAGE CORRECTION (1959 & EARLIER TRANSMISSIONS):* A new .020" thick gasket, Part No. 1193781 is being used in production after Transmission Code W-179 and may be used on all earlier transmissions to prevent exterior leakage. If the earlier gasket, Part No. 1333485 is used, it is suggested that two gaskets be used rather than one.

►*1960 TWIN TURBINE TRANSMISSION CODE NUMBER NOTE:* A code number is stamped on lower edge of reaction shaft flange directly to rear of high (left) accumulator and should be used as identification when ordering parts or for service procedure changes. The 1960 starting number is "A 001".

►*1960 TWIN TURBINE TRANSMISSION CASE PRODUCTION CHANGE:* A new transmission case, having the reverse ring gear pads machined to a larger diameter (to accommodate a new bronze reverse ring gear slipper), is being used in later production cars. The new slipper, Part No. 1190344, has tangs to engage mating slots in transmission case. If necessary to replace a reverse ring gear assembly in later units with the bronze slipper ring, ring gear Part No. 1196045 must be used. The new ring gear may be used for service replacement in earlier transmissions (without the slipper ring).

►*1960 STATOR SHIFT VALVE & SPRING PRODUCTION CHANGE & REPLACEMENT PARTS CAUTION:* Beginning with transmission Code "A 058" a new stator valve, Part No. 1196885, and spring, Part No. 1199089, is being used in production. The new parts are not interchangeable with parts used on earlier transmissions. *Stator valve setting in the accumulator or stator control linkage adjustments are not changed.*

DESCRIPTION: Two-speed hydraulically operated planetary type transmission and torque converter. *NOTE* - Different types of torque converters used as noted below. Manual selector lever on steering column controls operating range of transmission (Low, Drive, Reverse, Neutral, or Park), providing definite gear ratios (in addition to varying ratios of torque converter).

Torque Converters: Except for stator assemblies (see below) torque converter assemblies are similar for all models.

First Turbine—Located directly forward of the converter pump and has narrow band of vanes which receive all oil flow from pump. This turbine is mounted on a disk and hub assembly bearing on the turbine carrier hub and is geared to the second turbine (internal gear of planetary gear set is mounted on the disk hub).

Second Turbine—Located within first turbine case with broad band of vanes which receive all oil flow from first turbine and directs the oil flow back into the stator. This turbine is bolted to a turbine carrier which is splined on the input shaft. The planet pinions of the turbine gears are mounted on carrier and mesh with the internal gear on the first turbine disk hub and with the sun gear which is mounted on a bearing on the input shaft and coupled to stator free-wheel cam (gears are always in mesh but operate only when sun gear and stator are held stationary for torque converter action). With the stator unlocked and free-wheeling (when torque converter operating as a fluid coupling, sun gear is likewise free to rotate which allows all units to rotate at nearly the same speed as the converter pump.

1954 Stator - Located directly behind inner end of second turbine vanes. Receives oil from second turbine and redirects oil back to pump. Stator is mounted on reaction shaft by means of a free wheeling unit. The free wheeling cam is coupled to sun gear of turbine planetary gear set and controls the geared action of first and second turbines.

1955-60 Stator (Variable Pitch) - The single variable pitch stator is located directly behind inner end of second turbine vanes and receives oil from second turbine and redirects it back into pump. Stator is mounted on a reaction shaft by means of a free wheeling unit similar to previous models. Each of the twenty stator blades is on an individual control crank which is free to turn in its bearing in stator carrier. The carrier contains a piston which actuates blades through the control cranks when oil pressure is applied to one or both sides of piston. It is by this means that stator changes to "high" or "low" angle for normal cruising or for rapid acceleration.

LUBRICATI N

Check oil level at 1000 miles intervals and add oil as required. Drain and refill at 25,000 mile intervals.

►*CAUTION: Oil must be warm and engine must be idling when checking oil level. Warm up ngine b f re draining.*

Checking Oil Level: With oil warm and engine idling with control lever in "P" (Parking), position, check oil level as indicated on dipstick in filler tube in engine compartment (on right side between battery and engine). If level is more than 1" below FULL mark on rod, add recommended oil to bring level up to FULL mark *(CAUTION - Do not fill above FULL mark).* Distance between ADD OIL and FULL marks on dipstick is equal to approximately 1 pint of oil.

►*CAUTION: If oil level is consist ntly low wh n checked (indicating loss of 1 pint or mor p r 1000 miles), check transmission thoroughly for oil leaks.*

Draining & Refilling: With oil warm, drain transmission case, then drain torque converter (loosen one plug, then turn torque converter until second plug is downward and remove this plug). After complete draining, reinstall plugs. Install three quarts of recommended fluid through filler opening in case. Start engine and allow it to idle with selector lever in "P" (Park) position, then add fluid to bring level up a point 1¾" below FULL mark on dipstick. After transmission is at normal operating temperature, recheck fluid level. Oil should be at FULL mark on dipstick.

►*CAUTION: DO NOT FLUSH transmissi n wh n changing oil.*

Capacity (1954-56) - 10 qts. (refilling after draining). Install an additional 1¾ pts. (after overhaul). *NOTE - Some 1956 cars may require an additi nal quart f fluid (after draining) because of a d sign chang in torque converter.*

Capacity (1957) - 11 qts. (cars with early "Looped Handle" dipstick; 11½ qts. (cars with later "Right

CONTINUED N NEXT PAGE

DYNAFLOW DRIVE (C nt.)

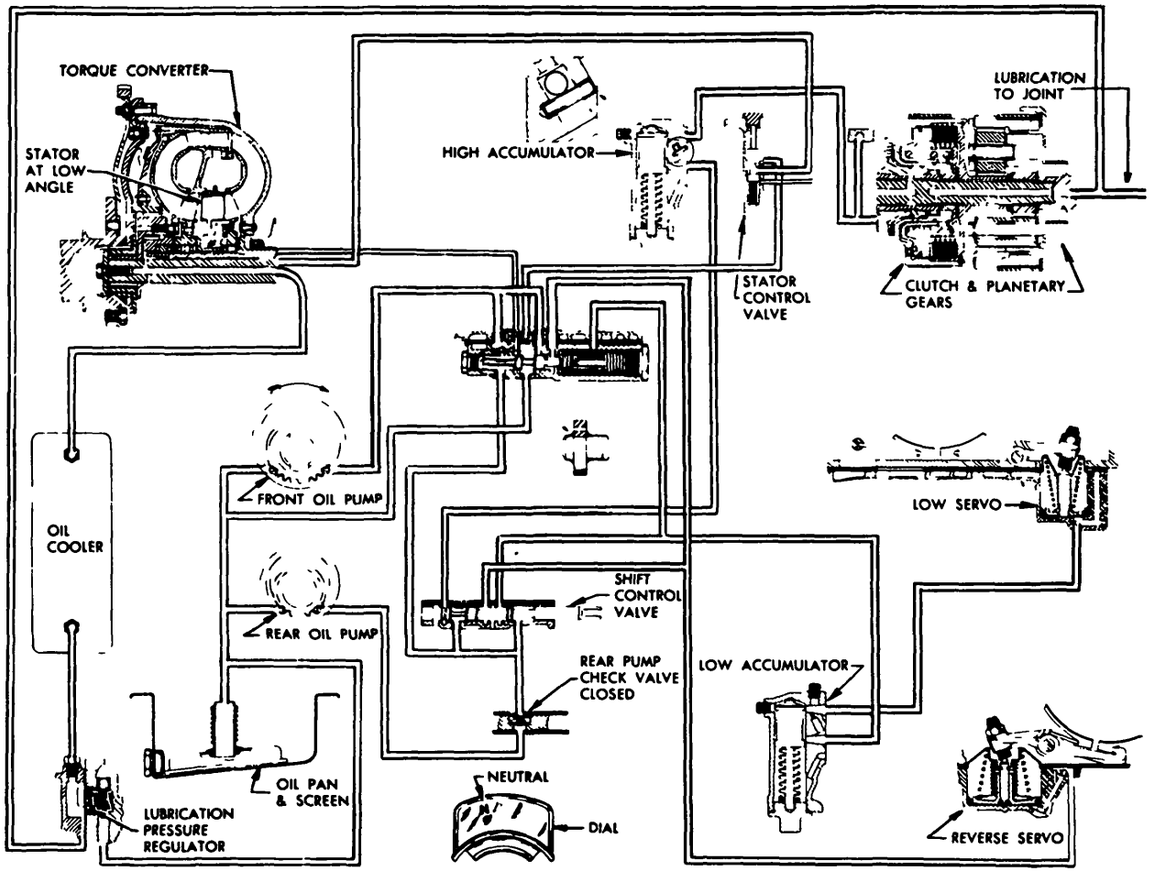
Angle Handle" dipstick. Install an additional 1¾ pts. (after overhaul).

Capacity (1958-60) - 12 qts. (refilling after draining). Install an additional 1¾ pts. (after overhaul).

Rec mmend d Fluid - Use only Automatic Transmission Fluid Type "A", having an AQ-ATF number embossed on can.

LINKAGE ADJUSTMENT

1954 MODELS



Thr ttl Linkag & Stat r Control Linkage Adjustment: Se CARBURETOR on Car Model pages.

Manual Control Linkagé: Transmission must be thoroughly warmed up (driven approximately 20 miles under traffic conditions with frequent starts and stops) and oil level must be correct. Then proceed as follows:

(1) Place shift control lever in Neutral "N" with detent plunger centered in detent notch, move lever until stop pin is against stop in dial housing, note movement of dial pointer. Repeat this operation in Low "L" position. Dial pointer movement should be approximately equal in both positions. If not, loosen control detent mounting bolts on steering column jacket, shift detent until dial pointer travel is equal. Place lever in Low "L" position, carefully bend dial pointer, if necessary, so pointer is in line with "L" on dial.

(2) Check parking mechanism by placing car on ramp or steep grade with control lever in Parking "P". Parking lock should hold securely. Place control lever in Neutral "N" and allow car to roll. If "clicking" ratchet noise heard, or if parking lock did not hold car on grade, adjust as follows: Place control lever in Parking "P" position, disconnect shift rod from shift idler lever on steering column, pull forward on rod and move car slightly to make certain locking pawl fully engaged (CAUTION—do not jerk on rod). Check movement at lower end of shift lever on left side of transmission case by pressing forward on lever (against spring tension) until definite stop is felt. This movement should be 1/8-3/16" beyond the parking "P" position. If spring travel not within these limits, control valve is out of adjustment (requires removal of torque ball). If spring travel correct, pull shift rod forward against stop, adjust shift rod clevis until clevis pin can just be entered in hole in idler lever with control detent engaged in Parking "P" position, then **lengthen rod by unscrewing clevis 3 full turns,** connect rod temporarily (may require readjustment in next step).

(3) Place shift control lever in Neutral "N" position with detent fully engaged. With transmission warm and engine idling at 600 R.P.M., move control lever from Neutral "N" to Drive "D" position slowly. Clutch should engage (noted by immediate decrease in engine speed) when tip of dial pointer is midway between "N" and "D" on speed ratio dial. Move control lever from Drive "D" to Neutral "N" position slowly. Clutch should disengage (noted by immediate increase in engine speed when tip of pointer is midway between "D" and "N" on dial. If clutch engagement and disengagement points not correct, readjust clevis on shift rod at shift lever (see (2) above), being careful not to disturb Parking adjustment. Do not connect shift rod permanently until adjustment (4) completed.

TWIN TURBINE DYNAFLOW HYDRAULIC CIRCUITS (TYPICAL)

►*CAUTION—When making above adjustment, do not change shift rod length so much that parking lock fails to hold or pawl contacts ratchet wheel in Neutral (check as directed in (2) above).*

(4) Check operation in Low "L" and Reverse "R" positions. Detents should be engaged and shift points should occur when tip of dial pointer is midway between "D" & "L" (Low), midway between "L" & "R" (Reverse). If shifts do not occur at correct points, check for bent transmission shift lever, bent valve operating upper lever ,or lever loose or incorrectly seated on shaft.

(5) After above adjustments completed, tighten clevis nut on shift rod clevis and permanently install clevis pin with plain washer and spring washer on each side of clevis.

►*CAUTION—Neutral Safety Switch and Back-up Light Switch must be checked after changing control detent and shift rod adjustments.*

Neutral Safety Switch Adjustment: With manual control linkage properly adjusted, ground primary terminal of distributor so that engine can be cranked without firing. Fully apply parking brake and place transmission control lever in "N" (Neutral) position. Place a narrow strip of masking tape on speed ratio dial so that upper end of dial pointer is visible. Make two marks on masking tape at ⅛" and 3/16" from center of pointer. Move control lever to "D" (Driving) position, turn ignition on and depress accelerator pedal to close accelerator vacuum switch. Slowly move dial pointer from "D" to "N" and note position of center of pointer at instant cranking motor just starts to operate. Release accelerator pedal. The center of the pointer should be between the two marks made on masking tape. If switch does not cut in within the specified limits, loosen switch mounting screws and move switch sideways as required for proper timing. Tighten mounting screws.

►*BACKING SWITCH NOTE*—No separate adjustment required (switch operation will be correct when neutral safety switch properly adjusted).

1955 MODELS

Throttle Linkage & Stator Control Linkage Adjustment: See CARBURETOR on Car Model pages.

Manual Shift Control Linkage Adjustment: 1) With shift control lever released, the stop screw in con-

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (Cont.)

trol shaft lower lever must be flush (±.010") with upper surface of stop plate. Adjust as required.

2) With shift control lever in "D" (drive) position, .035-.050" clearance must exist between lower lever stop screw and upper edge of large opening in stop plate (since this clearance cannot be readily checked, because of location, it may be assured by carefully performing the following adjustment).

(a) Disconnect lower shift rod clevis from idler lever and make sure that transmission shift lever is firmly held by detent in "D" position.

(b) With shift control lever on steering column in "D" position, push upward on the lever to hold stop screw in contact with stop plate, then adjust clevis in shift rod so that clevis pin will freely enter clevis and lever.

(c) Shorten length of rod by turning clevis 2 to 3 turns up on rod, then install clevis pin with anti-rattle washers and tighten clevis locknut. The number of turns at the clevis provides a specified clearance at the stop pin.

3) Park car on ramp or other slight grade with the control lever in "P" (parking) position to determine whether parking lock holds securely. Then let car roll with control lever in "N" (neutral) position and listen for a clicking or ratchet noise which indicates that the parking lock pawl is contacting the parking lock ratchet wheel. If parking lock fails to hold or ratchet noise exists, jack car up so that a wheel may be turned to rotate propeller shaft.

4) Loosen linkage adjusting lever lock bolt on side of rear bearing retainer. With transmission in "N" (neutral), tap rear end of lever upward until a slight ratchet noise is heard when propeller shaft is turned, then tap lever down just enough to eliminate the noise. Tighten lock bolt securely making certain that lever does not change position.

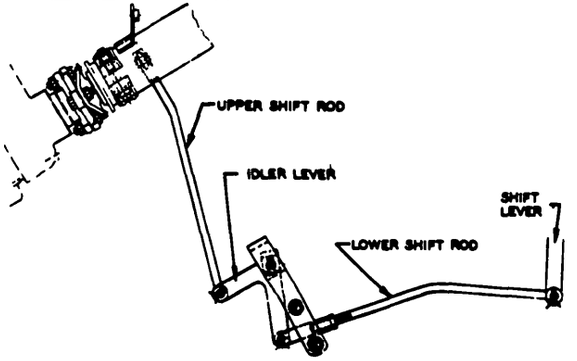
5) Set parking brake to prevent rear wheels from turning then start engine, with car still safely jacked up.

6) With transmission warmed up and engine idling at approximately 600 RPM, slowly move control lever from "N" to "D" position. The clutch should engage, as indicated by an immediate decrease in engine speed when center of dial pointer is midway between "N" and "D" on dial.

7) Slowly move control lever from "D" to "N" position. Clutch should disengage, as indicated by an immediate increase in engine speed, when center of dial pointer is midway between "D" and "N" on dial.

8) If points of clutch engagement and disengagement are not as specified, and all preceding linkage adjustments have been made correctly, it will be necessary to remove transmission oil pan, suction screen, and adjust position of shift control valve as described in "Valve & Servo Body Installation" under "Reassembly" below.

Neutral Safety Switch Adjustment: With manual control linkage properly adjusted, ground primary terminal of distributor so that engine can be cranked without firing. Fully apply parking brake and place transmission control lever in "N" (Neutral) position. Place a narrow strip of masking tape on speed ratio dial so that upper end of dial pointer is visible. Make two marks on masking tape at ⅛" and 3/16" from center of pointer. Move control lever to "D" (Driving) position, turn ignition on and depress accelerator pedal to close accelerator vacuum switch. Slowly move dial pointer from "D" to "N" and note position of center of pointer at instant cranking motor just starts to operate. Release accelerator pedal. The center of the pointer should be between the two marks made on masking tape. If switch does not cut in within the specified limits, loosen switch mounting screws and move switch sideways as required for proper timing. Tighten mounting screws.



►*BACKING SWITCH NOTE*—No separate adjustment required (switch operation will be correct when neutral safety switch properly adjusted).

Switch Wiring—Check wire connections on switch terminals for correct wiring (incorrect wiring may allow starter to crank with lever in other positions than Neutral or Park—may engage when shifting from Low to Drive during heavy pull), or backing lights may operate with shift lever in other than Reverse.

1956 MODELS

Throttle Linkage & Stator Control Linkage Adjustment: *See CARBURETOR on Car Model pages.*

Manual Shift Control Linkage Adjustment: Warm transmission to normal operating temperature and make sure transmission oil is at proper level. With lower shift rod disconnected from idler lever and manual control lever on steering column in "D" (Drive) position, adjust the stop screw at lower end of steering column into slot of spring until the spring is deflected .030-.035". Carefully move lower shift rod forward and backward to determine when it is in center of slotted hole in transmission shift lever (approximately .060" movement is possible). Adjust clevis until pin enters hole in idler lever without moving rod in slotted hole in transmission shift lever. Remove pin and assemble anti-rattle washers, clevis pin and cotter pin. Park car on ramp or other grade with control lever in "P" (Parking) position to determine whether parking lock holds securely. Then let car roll with control lever in neutral position and listen for a clicking or ratchet noise which would indicate that parking lock pawl is contacting parking lock ratchet wheel. If parking lock fails to hold or ratchet noise exists, jack up car so a wheel may be turned to rotate propeller shaft. Loosen linkage adjusting lever lock bolt on side of transmission rear bearing retainer. With transmission in neutral, tap rear end of lever upward until a slight ratchet noise is heard when propeller shaft is turned, then tap lever down just enough to eliminate the noise. Tighten lock bolt securely. With engine idling at 600 RPM (engine warm), slowly move control lever from "N" (Neutral) position to "D" (Drive) position. The clutch should engage, as indicated by an immediate decrease in engine speed when the center of dial pointer is midway between "N" and "D" on speed ratio dial. Slowly move control lever from "D" (Drive) position to "N" (Neutral) position. Clutch should disengage, as indicated by an immediate increase in engine speed, when center of speed ratio pointer is midway between "D" and "N" on speed ratio dial. If points of clutch engagement and disengagement are not as specified and all preceding linkage adjustments have been made correctly, it will be necessary to remove transmission oil pan and adjust position of the shift control valve. *See "Valve & Servo Body Installation" under "Reassembly" below.*

DYNAFLOW MANUAL LINKAGE

Neutral Safety Switch Adjustment: With manual control linkage properly adjusted, ground primary terminal of distributor so that engine can be cranked without firing. Fully apply parking brake and place transmission control in "N" (Neutral) position. Place a narrow strip of masking tape on speed ratio dial so that ends of letters "D" and "N" are visible. With transmission control firmly engaged in neutral detent, make pencil mark on masking tape at **right edge** of pointer, then make two marks on tape at 1/8" and 3/16" to right of first mark. Move control lever to "D" position, turn ignition on and depress accelerator pedal to close accelerator vacuum switch. Slowly move dial pointer from "D" to "N" and note position of **right edge** of pointer at instant the cranking motor just starts to operate. Release accelerator pedal. The **right edge** of pointer should be between the two marks made on masking tape at 1/8" and 3/16" out of neutral. If neutral safety switch does not cut in within specified limits, move it sideways on column jacket as required to obtain proper timing. Tighten mounting screws.

1957-60 MODELS

Throttle Linkage & Stator Control Linkage Adjustment: *See CARBURETOR on Car Model pages.*

Manual Shift Control Linkage Adjustment: 1) Move manual control lever carefully until transmission is shifted into its "D" (Drive) detent position (manual lever will seem to catch). Now move manual control lever toward "N" (Neutral), without lifting toward steering wheel, and notice how far it moves before contacting stop.

2) Move manual control lever until transmission is in "L" (Low) detent position. Then move manual control lever toward "R" (Reverse) and notice how far it moves before it contacts stop.

3) If movement from "D" detent to stop is the same as movement from "L" detent to stop, shift control linkage is correctly adjusted. If the above check indicates linkage to be incorrectly adjusted, adjust linkage as follows:

4) With manual control lever in "D", raise car and loosen adjusting clevis locknut on lower shift rod. Remove clevis pin, cotter key and spring washer. Make sure transmission is in "D" detent (center position of five possible detents).

5) Move idler lever so that upper shaft rod is forced upward as far as possible. Then turn clevis until clevis

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (Cont.)

pin will just slip in place without moving transmission shift lever. Shorten lower shift rod by turning clevis four complete turns. Install clevis pin spring washer and cotter key.

6) Lower car and check adjustment at manual control lever as indicated above. If movement of lever is not correct, readjust lower shift rod clevis slightly until movement is even.

7) Park car on a ramp or other grade with control lever in "P" (Park) position to determine whether parking lock holds securely. Then let car roll with control lever in "N" (Neutral) position and listen for a clicking or ratchet sound which indicates that parking lock pawl is contacting parking lock ratchet wheel.

8) If parking lock fails to hold or ratchet noise exists, jack car up so a wheel may be turned to rotate propeller shaft. Loosen linkage adjusting lever lock bolt on side of transmission rear bearing retainer. With transmission in "N" (Neutral), tap rear end of lever upward until a slight ratchet noise is heard when propeller shaft is turned, then tap lever down just enough to eliminate the noise.

9) With transmission warmed up and engine idling at approximately 600 RPM, slowly move control lever from "N" to "D" position. The clutch should engage, as indicated by an immediate decrease in engine speed when center of dial pointer is midway between "N" and "D" on speed ratio dial. Slowly move control lever from "D" to "N" position. Clutch should disengage, as indicated by an immediate increase in engine RPM, when center of speed ratio pointer is midway between "D" and "N" on speed ratio dial.

10) If points of clutch engagement and disengagement are not as specified, and all preceding linkage adjustments have been correctly made, it will be necessary to remove transmission oil pan and adjust position of shift control valve. *See "Valve & Servo Body Installation" under "Reassembly" below.*

11) After adjusting shift control linkage, make sure that dial pointer lines up with letters on face of dial. If necessary, adjust as follows:

Control Dial Pointer Position Adjustment: Place manual control lever in "N" position. Remove dial by prying between dial and housing until dial snaps out. Loosen nut holding pointer to transmission shaft. Correct pointer alignment leaving 3/16" to 1/4" between pointer and back plate. Tighten nut. Snap dial back in place and recheck pointer alignment.

Neutral Safety Switch Adjustment: Check and adjust shift control linkage. Place shift control lever in "N" (Neutral) position. Insert a 3/32" drill through gauging hole in operating lever and through gauging hole in switch body *(CAUTION - Be careful not to move shift control lever out of neutral position).* If gauging drill is now parallel with centerline of steering column jacket, switch timing is correct. If gauging drill will not go through holes or is not parallel, loosen two switch mounting screws and move switch sideways until gauge is parallel. Tighten screws. To check adjustment, turn on ignition switch, place shift control lever in "R" (Reverse) position, and make sure back-up lights are lit. Then set parking brake, place shift lever in "N" (Neutral) and make sure engine will start.

BAND ADJUSTMENT

►*BAND ADJUSTMENT NOTE: Bands cannot be adjusted with transmission installed in car. Adjustment is ordinarily required only at time of overhaul.*

Low & Reverse Band Adjustment: Remove band adjusting cover, then loosen locknut and turn adjusting screw clockwise until considerable resistance is felt indicating that band is in full contact with drum (low) or ring gear (reverse). Back off screw until just a trace of play can be felt by prying up on locknut with a screwdriver. From that point, back off screw 6 complete turns and tighten locknut finger tight. Note position of adjusting screw slot, then tighten locknut to 20-25 ft. lbs. Remove torque wrench and check to make sure that adjusting screw did not turn. Install band adjusting cover with a new gasket.

TESTING

If performance not satisfactory, make following tests with transmission thoroughly warmed up and at operating temperature:

Oil Level: Check oil level, add fluid as necessary to bring level up to FULL mark on dipstick, recheck performance with correct oil level. If car has been losing oil at rate of 1 pint or more each 1000 miles, make thorough check for oil leaks.

Manual Control Linkage: Check and adjust manual control linkage. See Linkage Adjustment.

Hydraulic Control System Pressures: Use Transmission Oil Pressure Gauge J-2575. Support rear end of car solidly with wheels off floor so that transmission can be operated. Remove transmission cover in floor pan for access to pressure take-off points.

Connect gauge and make tests as follows:

Front Oil Pump - Connect pressure gauge at pipe plug opening on left side of transmission case. Run engine at 500 RPM, check pressure with selector lever in Low, Drive, and Reverse ranges. Repeat tests at 1000 RPM, and at 1800 RPM in Low and Reverse only. See table below for correct pressures. Low or erratic pump pressures indicate air leaks in suction lines, improper pressure regulator valve action, or excessive pump clearances.

Front Pump Pressures

Selector Lever -	Low	Drive	Reverse
500 RPM	120 lbs.	90 lbs.	©120 lbs.
1000 RPM	180 lbs.	90 lbs.	
1800 RPM	180 lbs.	90 lbs.	

© - 100 lbs. on 1954 models.

Rear Oil Pump (1954-58 Models) - *NOTE - Not required on 1959-60 models.* Connect pressure gauge at pipe plug opening in lower flange at front end of rear bearing retainer. Run engine at 500 RPM, check pressure with selector lever in Low & Drive Ranges. Repeat test at 1000 RPM and at 1800 RPM. See table below for correct pressures. Low or erratic pump pressures indicate air leaks in suction lines (this will effect both pumps), improper pressure regulator valve action, excessive pump clearances or leaks in valve and servo body passages between pump and regulator valve.

Rear Oil Pump Pressures

Selector Lever -	Low	Drive
500 RPM	90 lbs.	90 lbs.
1000 RPM	180 lbs.	90 lbs.
1800 RPM	180 lbs.	90 lbs.

High & Low Accumulator - Connect pressure gauge at pipe plug opening on top of accumulator body (High - left side of car; Low - right side of car). Place selector lever in Drive Range (High Accumulator Test); Low Range (Low Accumulator Test). Run engine and check pressures at speeds indicated in table below. Low accumulator pressure may be caused by leakage past accumulator body gasket. If accumulator pressure is more than 10 lbs. lower than front pump pressure, check for leakage between accumulator and multiple disc clutch and for restricted or plugged metering orifice in accumulator dump valve.

Accumulator Pressures

Selector Lever -	Low	Drive
500 RPM	115 lbs.	80 lbs.
1000 RPM	175 lbs.	85 lbs.
1800 RPM	175 lbs.	85 lbs.

Stator (1955-60 Models) - Connect pressure gauge at pipe plug opening on left end of reaction shaft flange. Test pressure in Drive Range at 500 RPM, 1000 RPM, and 1800 RPM

Stator Pressures

1955 Models

Selector Lever -	Drive
500 RPM	70 lbs.
1000 RPM	75 lbs.
1800 RPM	75 lbs.

1956-60 Models

Selector Lever -	Drive
500 RPM	10 lbs.
1000 RPM	70 lbs.
1800 RPM	75 lbs.

TROUBLE SHOOTING

►*EXCESSIVE DYNAFLOW WHINE CORRECTION: (This condition is usually the result of excessive clearance between input shaft and bearing in the reaction shaft).* If transmission is to be disassembled to correct whine, perform the following:

1) Remove converter cover, twin turbine assembly, and sun gear, then mount dial indicator on end of input shaft with indicator button contacting reaction shaft. Position indicator button 90° to left of top center (facing end of shaft) then move input shaft away from and toward indicator while noting the gauge reading. Repeat this check at 45° to left of top center. If dial reading exceeds .005", excessive clearance exists between input shaft and bearing in reaction flange. 2) Before replacing bearing, remove reaction flange assembly and input shaft and observe the following: (a) Inspect bearing surface on input shaft. If surface appears abnormally rough or scored, replace input shaft; if not, polish journal area with crocus cloth. (b) Inspect the two oil seal rings toward rear of input shaft and the mating surface in the reaction shaft for scoring or other damage. If reaction shaft or input shaft shows evidence of scoring or other damage, replace worn or damaged parts.

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

3) If inspection reveals that condition of reaction shaft and input shaft are satisfactory, replace only the input shaft bearing (see Overhaul data).

4) If input shaft, reaction flange, or the bearing requires replacement, it will be necessary to replace the converter sun gear and planet pinions. *NOTE* - When installing reaction flange service bushing, be sure the assembly is supported on rear end of reaction shaft to prevent distortion of aluminum reaction flange.

CAR WILL NOT MOVE (Rear wheels may be locked or free).

1) With selector in any Range (rear wheels free). If car will not move for 1-8 minutes after standing over night - Check front pump oil pressure (see Testing) after allowing car to stand for several hours. If zero pressure noted, check pump for excessive clearances allowing pump to lose its prime. Check alignment of of bell housing and converter primary pump hub.

►*CAUTION: If this condition found, inspect Clutch and Bands for excessive wear due to slippage caused by low oil pressure.*

If car will not move after extended operation in Reverse - Check for air leaks in pump suction line (at rear oil pump gaskets), or excessive clearance in front pump (at pump gears and covers). Check alignment of bell housing and converter primary pump hub.

2) With selector in any Range (rear wheels locked). Parking lock engaged. Broken parts in transmission or rear axle. Parking brake applied.

3) With selector in Drive Range. Check front oil pump pressure and High Accumulator pressure. If OK, check for sticking Low Band Anchor Piston, remove and inspect Clutch-for worn or sticking clutch plates, leaking clutch seal rings. If High Accumulator pressure pressure low, also check rear pump Check Valve for correct installation and proper seating, check for leaks at accumulator body gasket, reaction flange gasket, clutch piston outer seal and clutch ball check valve, and leaks at sealing rings on reaction shaft flange and low drum.

4) With selector in Reverse Range. Check reverse band for displaced operating strut caused by too loose adjustment, improper installation, or broken band anchor (indicated by free up and down movement of band operating lever). If band assembly OK (no free movement of lever), check servo operation by running engine and shifting into Reverse. Remove Valve & Servo Body and check for reverse servo piston seal leaks.

EXCESSIVE SLIPPAGE (High engine speed in relation to car speed, or poor acceleration).

1) In all Speed Ranges. Low oil level. Incorrect manual control linkage adjustment. Air leak in oil pump suction pipe at oil screen sealing ring. Low front oil pump pressure caused by wear or excessive clearances in in pump. Leaks at front pump cover or reaction shaft flange, pressure regulator valve. Valve & Servo Body gasket. Pressure regulator valve defective.

2) In Drive Range. Incorrect manual control linkage adjustment. If High Accumulator pressure low, check for leak at accumulator body gasket; if gasket OK, check for leaking clutch sealing rings, sticking clutch piston, worn or sticking clutch plates.

3) In Low Range. Incorrect manual control linkage adjustment. Incorrect low band adjustment. Low band and drum worn or scored. If Low Accumulator pressure low, check for leak at accumulator body gasket; if gasket OK, remove Valve & Servo Body and check for gasket leaks or leaks at low servo piston seal.

4) In Reverse Range. Incorrect manual control linkage adjustment. Reverse band out of adjustment, strut out of place, or anchor broken. If front oil pump pressure low, remove Valve & Servo Body and check for gasket leaks and leaking reverse servo piston seal.

CAR CREEPS (Forward or Backward).

1) Creeps forward with selector in Neutral. Incorrect manual control linkage adjustment. Sticking low servo piston (check by removing low band adjustment cover). Sticking clutch caused by warped, binding, or incorrectly assembled clutch plates (not stacked properly with "dish" in same direction).

If Car Creeps only when engine accelerated to 2500 RPM - Check clutch vent ball checks in clutch piston and reaction shaft flange.

2) Creeps forward with selector in Reverse or backward with selector in Low. Incorrect manual control linkage adjustment.

SHIFTS ARE ROUGH

1) Low-to-Drive Shift. Incorrect Low Band adjustment. If High Accumulator pressure low, check for leak at accumulator body gasket and for dump valve or accumulator piston sticking down (top land of piston should be visible through top port in body). Sticking low band anchor piston (remove Valve & Servo Body to check), or incorrect piston location (see piston shimming data in-Valve & Servo Body Reassembly). Valve & Servo Body gasket leaks. Clutch plates worn or binding.

EXCESSIVE CHATTER OR CLUNK ON STARTING

►*CAUTION: Slight "clunk" when shifting into Low or Reverse is normal, and slight chatter when car starting to move in reverse (disappearing as soon as car in motion) is also normal.*

1) In Low & Reverse Range. Incorrect Low or Reverse Band adjustment. Engine and transmission mountings loose or incorrectly adjusted, thrust pad at transmission mounting broken (see Engine Mountings in Buick Special Data). Clutch plates warped, sticking, or incorrectly assembled (not stacked properly with "dish" in same direction). Reverse ring gear bushing worn. Planet pinion needle bearing rough.

NOISE IN TRANSMISSION.

►*CAUTION: Hum or low whine in Neutral or Parking is normal (due to free rotation of all planetary gears) and slight hum in Low and Reverse may be expected.*

1) Buzzing Noise. Low oil level. Front pump check valve hanging up on edge of gasket between valve and servo bodies. If noise noticed in Parking or Neutral, pressure regulator valve clearance in body may be excessive or orifice in valve land oversize (correct by replacing valve and body).

2) Clicking Noise. If noticed in all ranges, may be caused by foreign material in converter. If noticed only when car in motion, may be caused by parking lock pawl contacting ratchet wheel due to incorrect manual control linkage adjustment.

3) Abnormal Hum or Whine (see Caution above). If noted in all ranges, may be caused by worn parts or excessive front pump clearances (front pump noise will increase in Low and decrease at car speeds above 45 MPH. in Direct Drive). Check front pump for excessive clearances by testing for low pump pressure. If noise noted in all ranges except Direct Drive, may be caused by trouble in planetary gears (gears locked out in Direct Drive).

4) Squaling or Screeching following installation of Front Oil Pump. Pump driving gear installed backward.

►*CAUTION: Above condition must be corrected WITHOUT FURTHER OPERATION OF TRANSMISSION or severe damage will result.*

REMOVAL & INSTALLATION

1954-56 MODELS

Removal: *NOTE - Transmission and torque converter are removed and installed as an assembly.*

1) Raise car so that frame side rail is at least 20" off floor and place stands at front and rear to support car.

2) Disconnect torque tube from torque ball and move rear axle back to disengage propeller shaft from universal joint. Remove cranking motor splash pan, bell housing cover and bell housing hand hole cover.

3) Drain converter and transmission. Mark position of converter on flywheel to assure installation in same position and remove bolts attaching converter to flywheel. Disconnect pipes from oil cooler and disconnect cooler from transmission from rear mounting thrust plate. Remove cooler. Disconnect oil filler pipe at rubber hose and disconnect exhaust pipe hanger at right accumulator. Disconnect shift rod and speedometer cable at transmission.

4) Support transmission with a jack or hoist and remove four bolts attaching thrust plate to rear bearing retainer, then remove two nuts and plate which attach mounting pad to transmission support.

5) Raise engine and transmission just enough to relieve load on transmission support. Remove bolts attaching both ends of support to frame, then remove support and thrust plate as an assembly. *CAUTION*—If shims are found at this point, note their number and location so they can be reinstalled in the same position.

6) Support engine at rear end of lower crankcase so it will be supported while transmission is removed. ***CAUTION—Do not use bar with hooks placed over frame side rail. Brake lines will be damaged.***

7) On cars with air-conditioning, disconnect discharge and suction lines at compressor. This will avoid damaging flexible couplings when engine is raised and lowered.

8) Lower the transmission just enough so that bell housing bolts can be reached, then remove bell housing to crankcase bolts. Move transmission rearward to disengage hub of converter pump from crankshaft, lower transmission and remove it from beneath car.

Installation: With transmission and torque converter completely assembled, install unit in reverse order of removal procedure and note the following important points:

Alignment of Parts - Make sure that flywheel, converter primary pump, and converter cover positioned so that

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (Cont.)

paint marks (as made for removal) will be aligned when transmission installed.

►*CAUTION: This alignment necessary to maintain converter assembly balance.*

Shift Rod Installation - Check and adjust linkage when installing shift rod. See *LINKAGE ADJUSTMENT.*

Filling Transmission - See *LUBRICATION.*

Bell Housing Mounting Bolt Installation - Adjust lifting equipment so that bell housing meets engine crankcase squarely and engages the two dowels, then install all bell housing bolts with lockwashers. Tighten all bolts to 45-55 ft. lbs.

Transmission Support & Thrust Pad Installation - See *ENGINE MOUNTING in Buick Special Data.*

Converter Mounting Bolt Installation - Use the shank of an 11/32" drill to align bolt holes in flywheel and converter. Install bolts and tighten to 25-30 ft. lbs.

1957-58 MODELS

Removal: Transmission and converter are removed as an assembly as follows:

►*TRANSMISSION REMOVAL & INSTALLATION CAUTION:* Before removing transmission or disconnecting it from engine disconnect exhaust pipes from manifolds and loosen front muffler joints. After transmission is installed reassemble the exhaust system making sure that pipes are centered in frame member holes and that system is free from binds.

1) Raise car so that frame side rail is at least 20" off floor and place stands at front and rear to support car.

2) Disconnect torque tube from torque ball and move rear axle back to disengage propeller shaft from universal joint. Remove converter housing cover. Turn flywheel until one converter drain plug can be loosened sufficiently to provide an air vent, then turn flywheel until opposite drain plug is straight down. Remove plug and drain oil from converter. Drain oil from transmission.

3) Remove bolts attaching converter to flywheel. Disconnect and remove oil cooler lines. Disconnect speedometer cable, shift rod from shift lever, and stator operating control rod from lever on high accumulator.

4) Place transmission jack or hoist in position and adjust it to securely support transmission. Remove four bolts that attach thrust plate to rear bearing retainer, then remove two nuts and plate which attach mounting pad to transmission support.

5) Raise engine and transmission just enough to relieve load on transmission support, remove bolts attaching each end of support to frame, then remove support and thrust plate as an assembly *(CAUTION - Shims may or may not be used to fill space between transmission support and frame. If shims are present note the number and location of shims so they can be installed in their original positions).*

6) Place suitable jack under rear end of engine lower crankcase so engine will be safely supported while transmission is removed. *(CAUTION - Do not use bar or hooks placed over frame side rails as brake pipe on top of left side rail will be damaged).* Lower transmission just enough so that converter housing bolts can be reached.

7) With engine and transmission supported by separate jacks, disconnect converter housing from engine crankcase. Move transmission rearward to disengage hub of converter pump from crankshaft, lower transmission and remove from car.

Installation: 1) Turn flywheel so that one hole for converter attaching bolt is straight up and wide flange is down. Raise transmission into place with same equipment used for removal. Align converter attaching bolt holes with holes in flywheel before moving transmission forward against cylinder crankcase. Then with converter pump in correct position *(see "Converter Cover Installation" under "Bell Housing & Torque Converter Assembly Installation" above),* adjust lifting equipment so converter housing meets engine crankcase squarely and engages the two dowels. Install all converter housing bolts with lockwashers and tighten to 45-55 ft. lbs.

2) Raise transmission just enough to install transmission support and thrust plate, installing shims in their original positions between support and frame. Attach mounting pad to support with plate and nuts, and attach thrust plate to bearing retainer with four bolts and lockwashers.

3) Remove transmission hoist and engine support jack. Check converter drain plugs for tightness, then install converter housing cover. Attach oil filler pipe to oil pan and install oil cooler pipes. Connect torque tube to torque ball (tighten bolts after car is on floor).

4) Connect speedometer cable to driven gear sleeve and connect shift rod to shift lever on transmission, Connect stator operating rod to lever on high accumulator. Wipe all oil from outside of transmission and lower car to floor. Tighten torque ball bolts to 30-35 ft. lbs.

5) Fill transmission to proper level *(see "Draining & Refilling" above).* Check adjustment of control linkage *(see "Linkage-Adjustment" above).* Check adjustment of stator operating controls and throttle linkage *(see CARBURETOR on car model page).* Road test car and check for oil leaks.

1959-60 MODELS

Removal: 1) Raise car and place on jack stands so it is at least 20" off floor, then disconnect shock absorbers at axle end, track bar at axle, brake cable at equalizer, and brake pipe at torque tube bracket. Remove rear exhaust pipes. Disconnect torque tube from torque ball and move rear axle back to disengage propeller shaft from universal joint.

2) Remove torque converter housing cover and drain oil from converter, then drain oil from transmission. Disconnect converter from flywheel and disconnect speedometer cable. Disconnect shift rod from shift lever, and disconnect stator operating control rod from lever on high accumulator.

3) Place a transmission jack or hoist in position and adjust it to securely support transmission. Carefully mark transmission support and frame at each end of support so support may be reinstalled in same fore and aft position and at the same angularity.

4) Remove four bolts attaching thrust plate to rear, bearing retainer, then remove two nuts and plate attaching mounting pad to transmission support. Raise engine and transmission just enough to relieve load on support, then remove bolts attaching each end of support to frame and remove support and thrust plate as an assembly. *CAUTION - Shims may or may not be used to fill space between transmission support and frame. If shims are present, note number and location so they may be reinstalled in their original position.*

5) Place a suitable jack under rear end of engine lower crankcase so engine will be safely supported while transmission is being removed. *CAUTION - Do not use bar with hooks placed over frame side rails because brake pipe on top of frame left side rail will be damaged.* Lower transmission slightly and disconnect cooler pipes.

6) Lower transmission just enough so converter housing bolts can be reached, then with engine and transmission supported by separate jacks, disconnect converter housing from engine crankcase. Move transmission rearward to disengage hub of converter pump cover from crankshaft, then lower transmission and remove it from car.

Installation: 1) Turn flywheel so one hole for converter attaching bolt is straight up and wide flange is down, then raise transmission into place with same equipment used for removal. Align converter attaching bolt holes with holes in flywheel before moving transmission forward against engine crankcase. See illustration for location of driving bolt holes.

2) Adjust lifting equipment so converter housing meets engine crankcase squarely and engages the two dowels, then install all converter housing bolts with lockwashers. Tighten bolts to 45-65 ft. lbs. uniformly. Connect cooler pipes and raise transmission just enough to install transmission support and thrust plate. *CAUTION - Be sure to install any shims found between support and frame during removal of transmission. Locate support in its correct fore and aft position (as marked at removal) before tightening attaching bolts.*

3) Attach mounting pad to support with plate and nuts and attach thrust plate to bearing retainer with four bolts and lockwashers. *See "Buick Special Data" in car model section for engine mount adjustment.*

4) Install three flywheel-to-ring gear bolts and lockwashers. *NOTE - These bolts are 300M steel and bolts of lesser quality MUST NOT be used at this location. 300M steel bolts are identified by six radial marks on head.* Tighten bolts to 30-35 ft. lbs. Remove transmission hoist and engine support jack.

5) Check converter drain plugs for tightness, then install converter housing cover and install oil filler pipe on oil pan. Line up blind spline of propeller shaft with blank spline in universal joint and move axle assembly forward to engage propeller shaft and universal joint splines. Complete transmission installation by reversing removal procedure, then fill transmission with fluid and adjust control linkage.

DYNAFLOW DRIVE (C nt.)

OVERHAUL

TRANSMISSION UNIT REMOVAL (TRANSMISSION OUT OF CAR)

1954 MODELS

Converter & Bell Housing Removal: (1) Remove large hex plug and gasket from hub of converter pump cover, then remove the socket head set screw and lockwasher located in hub, using a hex wrench 5/16" across flats).

2) Remove all nuts, plain washers, and bolts attaching cover to converter pump. Insert a punch through bell housing hand hole and into a drive bolt hole to hold pump from turning.

3) Remove cover from pump, tapping or prying against edge to loosen it. Check seal for damage or evidence of oil leakage before removing cover.

4) Insert a screw driver into a hole in the first turbine disk to aid in removing the twin turbine assembly from input shaft. Push inward on shaft to avoid withdrawing it. Remove bronze thrust washer from turbine hub.

5) Remove retaining ring from groove in input shaft, using snap ring pliers, then remove bronze thrust washer and the sun gear.

6) Remove retaining ring from groove in reaction shaft and slide converter stator and free wheel roller race from reaction shaft. Remove stator bearing from reaction shaft if it did not come out with stator.

7) Pull converter pump forward from reaction shaft and immediately check for evidence of leakage. Radial streaks of fresh oil on back of pump and fresh oil streaks on face of pump body indicate leakage past oil pump seal. Before removing bell housing, check to see that all attaching bolts are tight. Loose bolts may be cause of oil leakage at this point.

8) Place transmission so that bell housing is over edge of bench. Take out bell housing attaching bolts, remove bell housing, check rubber oil seal for uniform compression (if seal not compressed uniformly, check around oil pump and in bell housing opening for burrs or foreign material preventing uniform seal compression). ***See Overhaul data for disassembly of converter stators and pump.***

1955-60 MODELS

Converter & Housing: 1) Completely drain converter, then remove all bolts and washers attaching cover to converter pump and remove cover. *NOTE - Check cover seal for damage or evidence of oil leak before removing.*

2) Remove reverse band adjustment cover and gasket with Tool J-2655. Shift transmission in "P" (Park) and pry up on reverse band operating lever with a screwdriver to unlock input shaft while removing the bolt, lockwasher, retaining washer, and thrust washer from front end of input shaft. Remove bronze thrust washer from first turbine support hub.

3) Insert screwdriver in first turbine support hole and slide turbine assembly off input shaft. Install Tool J-5806 over input shaft with beveled end outward. Pull stator forward on reaction shaft, grasp spacer and needle bearing race behind stator to retain all free wheeling parts of stator, then slide the assembly forward upon tool and remove from input shaft.

4) Pull converter pump forward from reaction shaft and immediately check for evidence of oil leakage. *NOTE - Radial streaks of fresh oil on back of pump and fresh oil streaks on face of front oil pump body indicate leakage past oil pump seal.* Before removing converter housing, check to see whether all attaching bolts are tight (loose bolts may be cause of oil leakage at this point).

5) Place transmission so housing is over edge of bench and remove it. Check seal for indications of leakage.

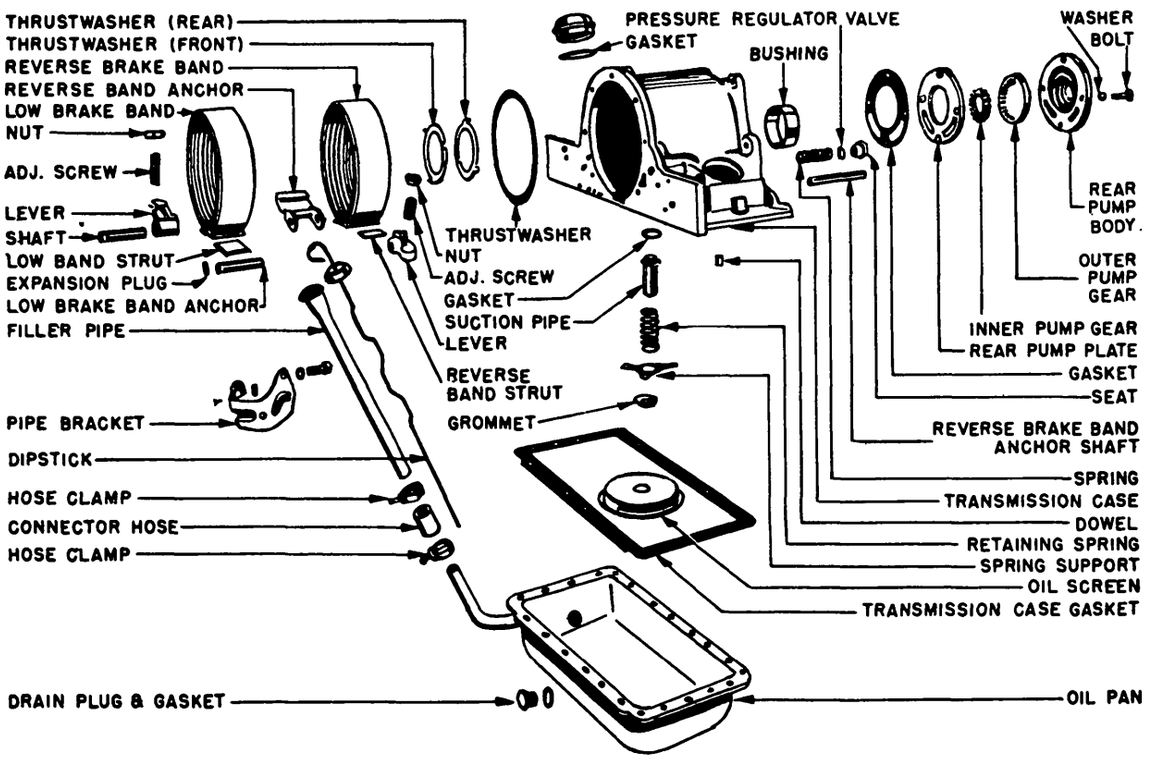
1954-60 MODELS

Oil Pan, Valve & Servo Body Assembly: *NOTE - These units can be removed with transmission in car.*

1) Remove shift lever to avoid damage to operating linkage, then hold lever forward while removing retainer nut so that linkage will not be strained and remove lever from shaft. Remove band adjustment covers and gaskets with Tool J-2655 (if not previously done) and turn transmission bottom side up. Remove oil pan and gasket and remove oil screen.

2) Disconnect valve operating rod from lever (upper) by placing a screwdriver on rod close to lever and exerting slight pressure. A spring loaded socket on rod engages ball stud on lever. Slightly loosen all valve and servo bolts, then remove bolts and lockwashers. *CAUTION - Do not loosen or remove slotted safety nuts on valve-to-servo body studs.*

3) Lightly pry upward on the assembly to free gasket between servo body and transmission case. Push shift control valve and lower operating lever inward to align lower lever with opening in transmission case, then remove the assembly. *CAUTION - Do not grasp slotted end of control valve.* Remove gasket and check for oil leakage.



4) Remove reverse band operating strut by extending fingers through adjustment hole to prevent strut from falling into transmission case and then release the strut by raising operating lever.

Reaction Shaft Flange, Oil Pump, Accumulators & Clutch: 1) Remove retaining ring from groove in input shaft, then loosen but do not remove caps on both accumulators. Remove bolts which attach accumulators and oil pump cover but do not remove stud nuts which attach these parts. Tap very lightly on rear of accumulator bodies with a soft mallet to loosen reaction shaft flange, then remove the assembly and gasket. Leave input shaft in place in transmission.

2) *NOTE - Check reaction flange gasket for indications of oil leakage.* Pull input shaft and clutch hub front thrust washer from clutch assembly, then remove clutch assembly. Compress low band with the operating lever while applying band clip, Tool C-2595, across strut flanges of band. Release lever and remove band, then remove struts which will drop into case.

3) Remove low band operating lever by threading a ¼"-20 capscrew into lever shaft and pulling shaft out of case.

CONTINUED ON NEXT PAGE

VARIABLE PITCH DYNAFL W TRANSMISSI N CASE, IL PUMP, & SERV BAND ASSY.

DYNAFLOW DRIVE (C nt.)

T rqu Ball & Univ rsal J int: Remove attaching bolts, then remove torque ball, inner and outer retainers, reinforcement and gaskets. Remove speedometer driven gear and sleeve assembly, then place transmission shift lever on cross shaft and push lever forward while turning universal joint until locking pawl engages ratchet wheel. Remove universal joint bolt, then pull joint from output shaft with Tool J-682-A if joint cannot be removed by hand. Remove transmission shift lever.

R ar B aring R tain r, R ar Bearing & Parking Lock Ratchet Wh l: *NOTE - After removal of torque ball, univ rsal joint and oil pan, these parts may be removed with transmission in car.* Disconnect valve operating rod from lever (if not previously done), then remove retaining bolts and retainer. Check gaskets for oil leakage. Remove rear bearing horseshoe washer from output shaft, then remove snap ring from rear of rear bearing and tap out bearing. Remove ratchet wheel outer retaining ring and slide wheel from shaft, then remove inner retainer ring.

R ar Oil Pump & Lubricati n Oil Pressure Regulator Valv : *NOTE - Aft r r moval of rear bearing retainer, thes parts can b r moved with transmission in car.* Remove retaining bolts, then remove pump body and pump gears. Remove drive key, then use a pointed tool to remove rubber cushion located under drive key on output shaft. Remove rear pump plate and gasket if they can be removed without prying. If plate is stuck, it can be tapped out after removal of planetary gear set. Remove lubrication oil pressure regulator valve seat from transmission case, using a 3/8" Allen wrench. Remove valve and spring.

Planetary G ar Set, R v rs Ring Gear & Reverse Band: Remove planetary gear set through front of case, then remove reverse ring gear. If rear pump plate and gasket were not previously removed, tap them out with a hammer handle from inside case. Thread a ¼"-20 bolt into reverse band anchor shaft to pull it from transmission case, then remove operating lever. Rotate reverse band until anchor can be disengaged, then remove it from band. Compress ends of reverse band and apply band installing clip, Tool J-2595, across strut flanges and remove band. Remove reverse ring gear thrust washer from case.

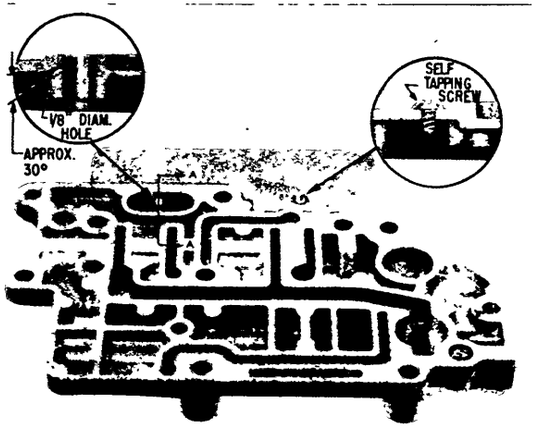
TRANSMISSION UNIT OVERHAUL

►*1955 SHIFT CONTROL VALVE PRODUCTION CHANGE:* Three control valves have been used in production, all of which are interchangeable. The valves are identified as follows: First (no extension), Second (plain extension), Third (grooved extension).

►*1955 CONVERTER COVER PRODUCTION CHANGE:* A later type converter primary pump cover having three impeller blades replaces the forme r type having impeller ribs completely around the cover. Either type can be used for service replacement.

►*1955 REACTION SHAFT & FLANGE, INPUT SHAFT, AND FRONT END REACTION SHAFT BEARING PRODUCTION CHANGE & SERVICE REPLACEMENT CAUTION:* A new needle bearing is used in later production cars in front end of the reaction shaft. The later type bearing has a larger inside and outside diameter and cannot be used for service replacement for the babbitt type bearing used in early production. The needle type bearing made necessary a change in reaction shaft and flange, and input shaft, In order to service a first type transmission to use the new bearing, it will be necessary to replace the above parts. *See "Disassembly of Components" below.*

►*1955 PRIMARY PUMP COVER SEAL NOTE:* Both a .120" and .135" diameter oil seal have been used in production. Either type may be used for service replacement.



►*1956 DYNAFLOW TRANSMISSION OIL LEAKAGE CORRECTION (OIL BLOWING OUT OF BREATHER OPENING):* On transmissions having numbers "0-1" to "0-93", the above condition is caused by a 1/16" hole in output shaft (formerly used to lubricate rear bearing retainer) being uncovered by open end of horseshoe washer which is located in groove directly ahead of rear bearing retainer ball bearing *(NOTE- An unused groove will be found directly forward of the groove in which the 1/16" hole is located, and serves to identify shafts requiring correction. This unused groove can be observed through breather hole when transmission is removed).* To correct this condition with transmission in car, remove the rear axle assembly, torque ball assembly and universal joint. Flare one end of a 4" piece of 1/4" soft copper tubing until it fits snugly in the .290" diameter hole in end of output shaft. Cut off tube approximately 2" from flared end, then flare cut-off end to obtain a press fit in the .297" section of hole *(NOTE -* File flare outside diameter to obtain a suitable fit). Lightly tap copper tube in end of output shaft with suitable punch or 1/4" diameter rod, making certain that copper tube is fully seated with a snug fit *(CAUTION - Excessive or hard blows may collapse copper tube and restrict oil passage through tube).* Reinstall torque ball, universal joint, and rear axle assembly *(NOTE - The above procedure may also be used when transmission is removed from car for service not requiring removal of rear bearing retainer).* When transmission is removed and removal of rear bearing retainer is required, proceed as follows: Insert a 1/16" diameter welding rod approximately 1" long into oil hole until it bottoms, then insert a 1/4" diameter rod or punch in end of output shaft and tap with hammer to bend end of welding rod. Leave punch in place in shaft and snip off end of welding rod flush with output shaft outside diameter, upset this end with a cold chisel to lock plug in place. Install horseshoe washer on shaft so that welding rod plug is at open end of washer (this will allow washer to seat in groove). *NOTE - To indicate that the output shaft has been modified, as indicated above, use a chisel and make a dash (–) in front of the "O" of transmission code number.*

►*1956 DYNAFLOW FRONT PUMP SEAL SERVICE REPLACEMENT (NEW TYPE SPRING LOADED CARBON SEAL FOR USE WITH TRANSMISSIONS HAVING ALUMINUM PRIMARY PUMPS):* The new carbon seal is designed to seat against flat face of primary pump hub, making it possible to use seal on pumps which would normally be replaced because of scored hub in area of present seal. It is suggested that new seal be installed in transmission having primary pump which would ordinarily be replaced because of sealing difficulties. Install seal as follows: After removal of old seal, inspect bore for burrs or damage. Correct any defects to be sure of a good press fit on seal outer diameter (leading edge of bore in pump body should have a slight radius). Clean up face of hub on primary pump with crocus cloth and inspect for burrs, dents or gouges. If deep marks are found, replace pump and install regular production seal. Coat outside diameter of seal with Permatex No. 3, then using crankshaft oil seal installer J-5250-1, press seal into pump body using an arbor press, drill press, or tap evenly into place with a mallet until flange of seal is down against face of pump body *(CAUTION - Do not mar or press on carbon face, and do not cock seal during installation as damage to seal will result. Also, under no circumstances should the carbon face seal be used with a steel primary pump).* Wipe both seal face and hub face on primary pump with a clean cloth to remove all traces of grit and other foreign material; then coat both faces with clean Dynaflow oil before assembling. When installing primary pump on transmission, use extreme care not to mar the carbon seal face with end of hub sleeve. When transmission is installed in car, the seal will automatically position itself and is constructed so as to compensate for normal play, deflection, and eccentricity.

►*1957 VALVE BODY PRODUCTION CHANGE:* The later valve body prevents oil being dumped above the screen as ports in the valve body have been changed. The later valve body is identified by absence of ports in valve boss. Valve is identified by a groove in valve land adjacent to actuating lever end. These parts are interchangeable; however, the adjusting procedure is different when later type valve body is used. *Se "Valve & Servo Bodies" below.*

►*1957 VALVE BODY PRODUCTION CHANGE & SERVICE NOTE:* To prevent the possibility of air being drawn into hydraulic system during cornering, the valve body vent hole has been relocated to a position in the rear pump suction passage. Whenever oil pan

CONTINUED ON NEXT PAGE

1957 VALVE BODY CHANGE

DYNAFLOW DRIVE (C nt.)

is removed on 1957 cars (early), the control valve should be removed and the original 1/8" vent hole should be plugged with a self-tapping screw. A new hole should be drilled in the rear oil pump passage as shown in the illustration.

►*1957 DYNAFLOW SPRAG CLUTCH PRODUCTION CHANGE:* A new sprag clutch, Part No. 1179222, having two bronze drag strips on inner diameter to provide a bearing surface that rides on reaction shaft when freewheeling, is used in production and for service replacement. This later assembly is interchangeable with the assembly used in 1956 & early 1957 models.

►*1957 THRUST WASHER (BETWEEN PLANET CARRIER & CASE) NOTE:* There is no thrust washer (front or rear) at this location. DO NOT ATTEMPT TO INSTALL THEM.

►*1960 TWIN TURBINE TRANSMISSION CODE NUMBER NOTE:* See *"Changes, Cautions, Corrections"* above.

►*1960 TWIN TURBINE TRANSMISSION CASE PRODUCTION CHANGE:* See *"Changes, Cautions, Corrections"* above.

►*1960 STATOR SHIFT VALVE & SPRING PRODUCTION CHANGE & REPLACEMENT PARTS CAUTION:* See *"Changes, Cautions, Corrections"* above.

1954 MODELS

Converter Stators & Pump: Disassembly—Pry retaining ring out of groove in first turbine, insert screw driver in hole in disc and lift disc and hub assembly out of first turbine. Lift second turbine and carrier assembly out of first turbine. Remove four bolts with lockwasher and pinion pin lock plate from second turbine. It is not necessary to lift turbine from carrier at this time. Remove pins, then remove the four planet pinions and thrust washers from turbine carrier. Remove bearing rollers (22) from each pinion. Remove ball bearing from rear side of converter stator, push the free wheel roller race out of free wheel cam in front side of stator, then remove all rollers, cups, and springs from the cam. Pry the pilot bearing retaining ring out of its groove in hub of converter pump cover, then push pilot bearing and bearing retainer out of the hub.

Inspection—Wash all parts in clean solvent and dry with air. Inspect all planetary gear teeth, thrust washers, bushings, and related bearing surfaces for excessive wear, scoring or other damage. Inspect free wheel roller springs for distortion and check rollers and race for nicks or burrs. Small nicks or burrs should be removed with an Arkansas stone and polished with crocus cloth. Inspect converter pump, turbines, and stator for damaged or cracked vanes. Inspect rear edge of first turbine hub (at ring gear) and the mating thrust surface on second turbine (around carrier) for wear, scoring or other damage. Inspect turbine carrier for excessive wear or other damage. ***(If second turbine or the carrier must be replaced, use care in separating them to avoid damage to the good part).*** Inspect converter pump hub for scores and for wear caused by the front pump seal.

►***INSPECTION CAUTION***—Converter oil leaks, oil pump body leaks, front oil pump noise, and excessive wear of front pump bushing and oil seal may be caused by (1) Excessive runout of converter pump hub; (2) Excessive runout of flywheel face; (3) Misalignment of bell housing. When any of these conditions are encountered and there is any doubt as to their true cause see Alignment of Converter and Bell Housing (below).

Assembly—***(CAUTION—If stator was replaced, make certain that new stator has correct number of vanes—12 vanes, Buick 40; 20 vanes, all others).***

1) Place input shaft pilot bearing retainer in hub of converter pump cover with shouldered side upward, push the pilot bearing into hub of cover until outer race bears against shoulder in hub, then install retaining ring.

2) Install springs and cups on free-wheel roller race in cam on front side of converter stator, then use a suitable thin blade to depress the cup and spring while inserting each of the free wheel rollers.

3) Install the ball bearing in rear side of stator, using care to start it squarely into place. The bearing must be fully seated in counter-bored recess and outer race must be free to turn.

4) If second turbine was separated from carrier, make sure that counter-bored recess in turbine and mating surfaces of carrier are free of burrs and clean, then apply a thin film of oil to these surfaces.

5) Support carrier on suitable blocks, install several pinion pins to serve as pilots, then place turbines in position so that carrier is started squarely into recess in turbine. Use a hammer and hardwood dowel or other soft punch to tap turbine down over carrier. ***Avoid distortion of turbine by using light blows applied midway between holes and alternated from side to side to keep parts square with each other.***

►***CAUTION—If turbine cannot be assembled on carrier with moderate force, remove it and check for burrs in counter-bored recess.***

6) With turbine and carrier supported on wood blocks, hub side down, assemble and install the four pinions as follows: Place planet pinion on thrust washer, install 22 needle bearing rollers in pinion and place a thrust washer on top of pinion. ***(NOTE—A loading tool can be made by using a piece of steel rod 3/8" in diameter by 11/16" long. Place tool in center of pinion and install needle bearings around tool).*** Place assembled pinion in carrier and install a pinion pin with notched end up. After loading tool is pushed out of carrier, slide block under pinion pin to hold it in place. Turn all pins so that notch faces center of carrier.

7) Install pinion pin lock plate so that it enters notches in all pins, then install the four turbine-to-carrier bolts with lockwashers. Place second turbine and carrier assembly in first turbine, then install first turbine disc and hub assembly over second turbine.

8) Rotate disc until ring gear meshes with carrier pinions, then align driving lugs on disc with notches in first turbine and push the assembly all the way into turbine.

9) ***CAUTION—Turbine disc retaining ring is installed exactly as follows:*** Place the ring in position with "dished" side upward so that the inner edge will bear firmly against disc when ring is engaged in groove in first turbine. Start one end of ring into grove in turbine, then twist ring upward in order to lay ring flat on disc so that it can be progressively entered into groove all the way around.

10) Make certain that ring is fully seated in groove and that inner edge bears against turbine disc. Tap inner edge down against disc if it has raised up,

1955-58 MODELS

►*1955 (LATE) VARIABLE PITCH STATOR PISTON CHANGE & REASSEMBLY NOTE:* The crank thrust washer and retaining ring were eliminated in late 1955 and succeeding production, making it necessary to use a special fixture (made locally) for reassembly. *See "Stator Fixture Note" below.*

Converter Twin Turbine & Sun G ar: Disass mbly - Pry retaining ring out of groove in first turbine, insert screwdriver in hole in disc and lift disc and hub assembly out of first turbine. Lift second turbine and carrier assembly out of first turbine. Remove tanged thrust washer (this washer may remain in carrier or be found on top of sun gear). Slide sun gear assembly off the first turbine being careful to hold sun gear bearing in place. Lift first stator assembly out of first turbine. Remove bronze thrust washer and sprag from sun gear. Lay first turbine on bench with narrow edge of vanes up. Pry off cupped thrust washer, then remove first stator bearing and sprag assembly. Using a brass drift, carefully tap first stator bearing to remove bearing and cupped thrust washer.

Converter Variable Pitch Stator: Disassembly—Remove stator thrust washer and selective spacers from rear side of stator, remove tool J-5806 (installed on input shaft when converter removed from transmission), then remove free wheel rollers and springs from the cam. Pry retaining ring from groove in stator blade rear carrier, and remove free wheel cam and three driving keys. Use screwdriver, tool J-5826 to remove stator blade front carrier screws and lockwashers, then remove front carrier which is also held to rear carrier by two dowels. Remove retaining ring and thrust washer (on early cars), from hub of stator piston. Remove stator blade carrier ring and all stator blades from rear carrier. Remove stator piston with sealing ring from rear carrier.

Inspection (All Converter Parts)—Wash all parts in clean solvent and dry thoroughly. Inspect converter pump hub for scores and for wear caused by front pump seal. (If pump is suspected of leaking oil, it may be tested as described below). Inspect converter pump and turbines for cracked or damaged vanes. Inspect turbine carrier, planetary gear teeth, thrust washers, bushings and related bearing surfaces for wear, scoring or damage. Inspect stator free wheel rollers and cam for nicks or burrs, which should be removed with an Arkansas stone, and polished with crocus cloth. Discard any roller springs that are damaged or distorted. Inspect stator blades for distortion, cracks, loose on cranks, or other damage. Inspect piston oil seal ring and bore of blade carrier for scoring or wear. If bushings of carrier are worn, they should be replaced, using installer tool J-5913. If second turbine or the carrier must be replaced, use care in separating

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

them to avoid damage to the good part. With second turbine suitably supported, tap carrier free of counter-bore in turbine, using a hammer and a hardwood dowel or other soft punch. *CAUTION—Do not drive against surface of thrust boss in carrier.*

Variable Pitch Stator (First Type): Reassembly—1) Install oil sealing ring in stator piston, then tilt piston slightly to install it in bore of rear carrier, placing piston so that hub extends through flanged end of carrier. Mount piston on a suitable support (such as ring of spring compressor J-2590) so that piston is held up against flange of carrier.

2) With stator blade carrier ring resting on bench with holes upward, insert stator blades with concave sides upward and cranks toward center of ring. Blades should be in the nearly closed position. Carefully place the carrier ring with blades in position on rear carrier so that all cranks engage the groove in carrier. Install thrust washer over cranks and install retaining ring in groove of piston hub.

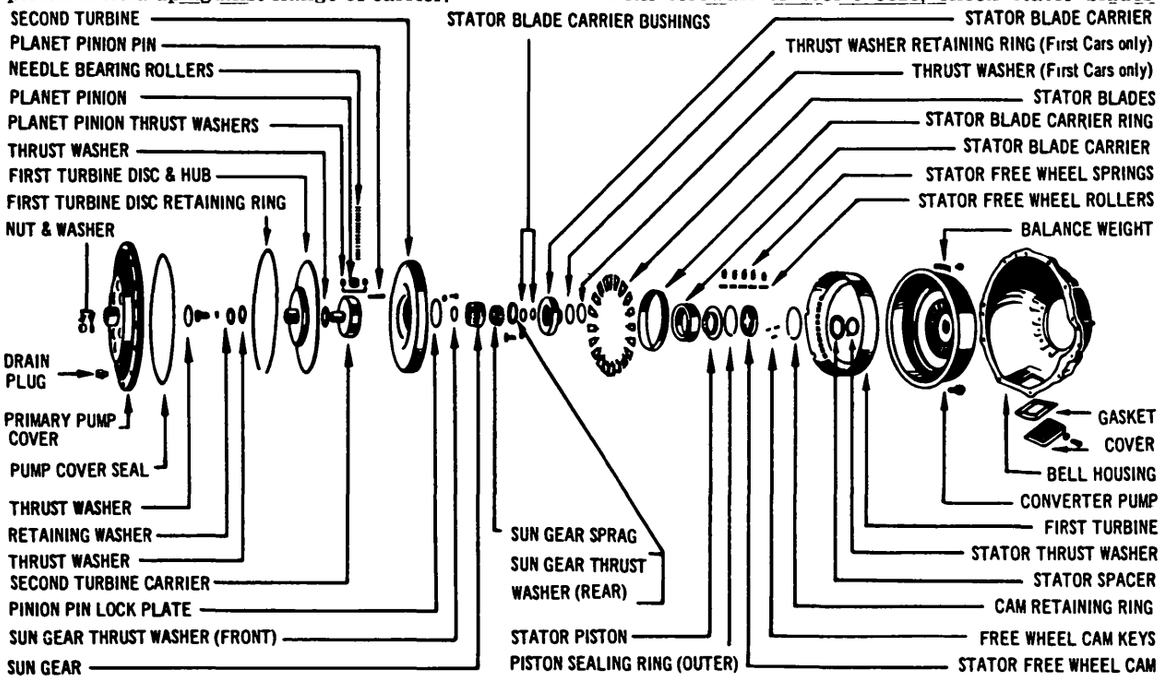
3) Place front carrier over rear carrier so that screw holes are aligned when dowels enter their holes, then install screws with countersunk external tooth lockwashers. After screws are turned down snug with screwdriver tool J-5826, check stator blades and piston for smooth operation. Blades should move throughout range without binding. If they do not, check for misalignment of cranks in carrier grooves. Tighten screws to 10-12 ft. lbs., and make sure that blades still operate freely.

4) Install free wheel cam with three driving keys and retaining ring in carrier. Check free wheel springs and alter length as necessary to assure equal length of all springs. Place free wheel rollers and springs in cam, with rollers at rounded ends of cam recesses.

5) Install tool J-5806 through free wheel rollers by turning it slightly clockwise so that flat end of tool is flush with rollers and cam. Make certain that surfaces of cam, spacers and thrust washer are free of grease and dirt, then install spacers and washer with tangs of washer extending through holes in spacers and cam.

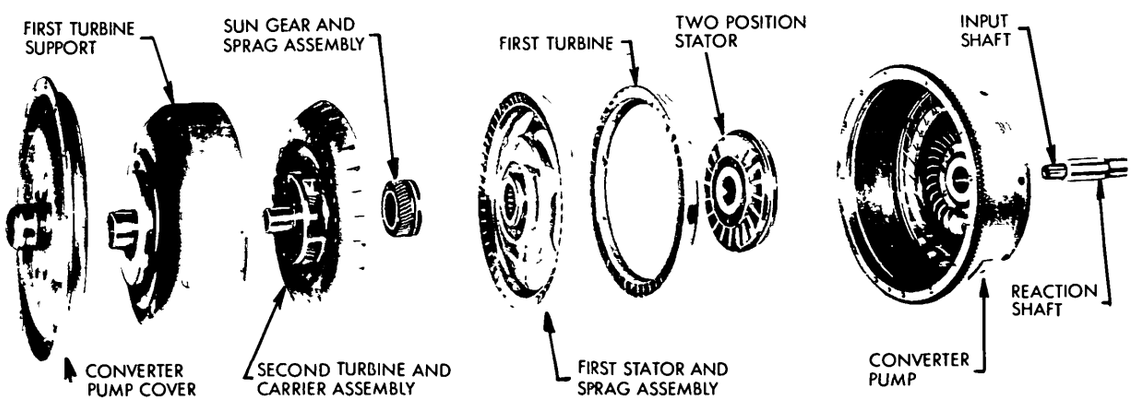
Variable Pitch Stator (Second Type): Reassembly— ***NOTE—A special fixture which can be made locally is required for reassembly of the second type stator. See Stator Fixture Note below.***

1) Insert stator piston and oil seal in rear carrier and push it to the extreme forward position. Place rear carrier on center block of fixture to hold piston in position.



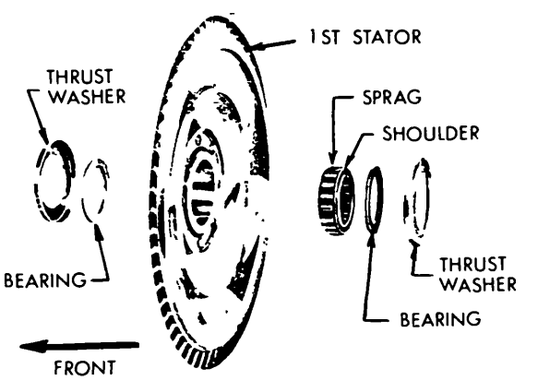
2) Place stator outer ring on two outer blocks of fixture, with crank pin up. Holding the blade in the approximate "low pitch" position insert the crank pin in the outer ring. Then rotate the blade to bring the crank throw into the piston groove. Hold the piston, blades, and outer ring together while installing the blades.

3) Install the remainder of the blades, working in a clockwise direction. To insert the last blade it will be necessary to tilt the adjacent three blades.



4) Install the front carrier and bolt into place. Be sure that blades operate freely in carrier. Complete the assembly of stator as indicated for first type stator (above).

►**Stator Fixture Note**—The fixture is composed of four blocks of wood as follows: One piece ¾" x 3½" x 11" (base piece). One piece ¾" x 3" x 2" (center piece). Two pieces 1⅛" x 3½" x 2¼" (end pieces). Place base piece on bench and position center piece in center of base piece so that each end of center



CONTINUED ON NEXT PAGE

1955-56 VARIABLE PITCH DYNAFLOW TORQUE CONVERTER & BELL HOUSING

TWIN TURBINE DYNAFLOW TORQUE CONVERTER ASSEMBLY

FIRST STATOR ASSEMBLY

DYNAFLOW DRIVE (C nt.)

piece is ¼" from edge of base. Position the two end pieces on extreme ends of base piece so they lay lengthwise across base piece flush with end and sides. Stator hub will rest on center piece and ring will rest on the two end pieces for installation of the blades.

Converter Twin Turbine & Sun Gear: Reassembly - 1) Install sprag in bore of sun gear with shouldered end toward outside then carefully press bearing into place. Check operation of sun gear sprag clutch by sliding sun gear assembly on reaction shaft with gear end toward front of transmission. When viewed from front of transmission sun gear must rotate freely clockwise and lock in a counterclockwise direction.

2) Lay first stator on bench with thin edges up. Place first stator sprag in hub of first stator with shoulder down. Install one bronze bearing and cupped thrust washer on each side of sprag. Check operation of first stator sprag clutch by sliding the first stator on reaction shaft with thin edges of blades toward front of transmission. The first stator must turn freely clockwise and lock in a counterclockwise direction when viewed from front of transmission.

3) If second turbine was separated from carrier, make certain that counterbored recess in turbine and mating surfaces of carrier are clean and free of burrs, and apply a film of oil to these surfaces. Support carrier on suitable blocks, install several pinion pins to serve as pilots, then place turbine in position so that carrier is squarely started into recess in turbine. Use a hammer and hardwood dowel to tap turbine down over the carrier. Avoid distortion of turbine by using light blows applied midway between holes and alternated from side to side to keep parts square with each other. *(CAUTION - If turbine cannot be assembled on carrier with moderate force, remove it and check for burrs in counterbored recess).* With turbine and carrier supported on wood blocks, hub side down, assemble and install the four pinions as follows:

4) Place planet pinion on a thrust washer, install 22 needle bearings in pinion and place a thrust washer on top of pinion. *(NOTE -* A loading tool can be made locally from a piece of 3/8" steel rod, 11/16" long which will simplify loading and installation of pinion). Place assembled pinion in carrier and install a pinion pin with notched end up. After loading tool is pushed out of carrier, slide a block under pinion to hold it in place. Turn all pins so that notches face center of carrier. Install pinion lock plate so that it enters notch in all pins, then install four turbine-to-carrier bolts with lockwashers.

5) Place first stator in first turbine with thin edge of blades up. Place sun gear assembly on first stator with gear end up. Place thrust washers (with tangs) in planet carrier. Use chassis lube to prevent washer from shifting during assembly. Place second turbine and carrier assembly in first turbine, making sure pinions mesh with sun gear. Place thrust washer on carrier, then install first turbine disc and hub assembly over second turbine. Rotate disc until ring gear meshes with carrier pinions, then align driving lugs on disc with notches in first turbine and the assembly all the way down into turbine.

6) Note that turbine disc retaining ring is "dished". Place ring in position with the "dish" upward so that inner edge will bear firmly against the disc when ring is engaged in groove of first turbine. Start one end of ring into groove in turbine, then twist ring upward in order to lay ring flat on the disc so that it can be progressively entered into groove all the way around. Make certain that ring is fully seated in groove and that inner edge bears against turbine disc. Tap inner edge down against disc if it has raised up.

1959-60 MODELS

Converter Twin Turbine & Sun Gear: Disassembly - Drive three roll pins, holding first turbine blades to turbine support, inward about ¼" using a 1/8" punch. *NOTE - It is not necessary to remove roll pins.* Make a tool locally (see "Tool Note" below) and attach tool to a slide hammer. Place edge of tool under edge of first turbine, then hammer first on one side, then on the other, to move first turbine straight up out of turbine support. Lift first stator assembly out of support and set aside, then lift second turbine out of support. Pry off cupped thrust washers and remove first stator bearings and sprag assembly from sun gear, then lift second turbine assembly out of first turbine support.

►*TOOL NOTE:* Use a piece of steel bar stock ¼"x1"x1½" and drill a hole in the middle, ¾" from one side, to accommodate the end of a slide hammer. Weld a nut (same threads as on end of slide hammer) over hole into which a slide hammer can be threaded.

Disassembly (Two Position Stator): Remove stator thrust washer and selective spacers from rear side of stator, remove Tool J-5806, then remove free wheel rollers and springs from cam. Pry retaining ring from groove in stator blade rear carrier and remove free wheel cam and three driving keys. Use Tool J-5826 and remove stator blade front carrier screws and lockwashers, then remove front carrier which is also held to rear carrier by two dowels. Tilt three or four blades toward low angle position and slide the crank pin ends clockwise around stator piston groove. The next blade and all succeeding blades will then have enough clearance for removal.

Inspection (Twin Turbine & Stator): Wash all parts and dry thoroughly, then inspect converter pump hub for scores and for wear caused by front pump seal. Inspect converter pump and turbine for cracked or distorted vanes. Inspect turbine carrier, planetary gear teeth, thrust washers, bushings and related bearing surfaces for excessive wear, scoring or other damage. Examine stator needle thrust bearing which is staked in converter pump. If damaged or worn, carefully drive back the other staking and remove bearing. *NOTE - Stake a new bearing assembly very lightly (just enough to keep it from falling out).* Inspect sprag bores in first stator and sun gear, also outer diameter of reaction shaft for brinelling, wear or burrs. Inspect sprags and sprag cages for distortion or excessive wear. Replace sprag if cage distorted. *CAUTION - If sprag clutches are dropped or handled in any manner which dislocates a sprag or distorts either cage, the assembly must be replaced.* Inspect stator free wheel rollers and cam for nicks or burrs whichshould be removed with an Arkansas stone and polished with crocus cloth. Discard any roller springs that are damaged or distorted. Inspect stator blades for distortion, cracks, loose on cranks, or other damage. Inspect piston oil seal ring and bore of blade carrier for scoring or wear. If bushings in carrier are worn, they should be replaced using Tool J-5913 to properly locate new bushings. If second turbine or carrier must be replaced, use care in separating them to avoid damage to the part not requiring replacement. With second turbine suitably supported, tap carrier free of counterbore in turbine using a hammer and a hard wood dowel. *CAUTION - Do not driv against surface of thrust boss in carrier.*

Reassembly (Two Position Stat r): *NOTE - A special wooden fixture which can be made locally is required for reassembly of the stator. See "Stator Fixtur Note" below.*

1) Insert stator piston and oil seal in rear carrier and push it to the extreme forward position. Place rear carrier on center block of fixture to hold piston in position.

2) Place stator outer ring on two outer blocks of fixture with crank pin up. Holding the blade in the approximate "low pitch" position insert the crank pin in the outer ring. Then rotate the blade to bring the crank throw into the piston groove. Hold the piston, blades, and the outer ring together while installing the blades.

3) Install the remainder of the blades, working in a clockwise direction. To insert the last blade it will be necessary to tilt the adjacent three blades.

4) Install the front carrier and bolt into place. Be sure that blades operate freely in carrier. Complete the assembly of stator as indicated for first type stator (above).

►*STATOR FIXTURE NOTE:* The fixture is composed of four blocks of wood as follows: One piece ¾"x3½" x11" (base piece). One piece ¾"x3"x2" (center piece). Two pieces 1 1/8" x 3 1/2" x 2 1/4" (end pieces). Place base piece on bench and position center piece in center of base piece so that each end of center piece is ¼" from edge of base. Position the two end pieces on extreme ends of base piece so they lay lengthwise across base piece flush with end and sides. Stator hub will rest on center piece and ring will rest on the two end pieces for installation of the blades.

Reassembly (Twin Turbine): 1) If second turbine separated from carrier, make sure that counterbored recess in turbine and mating surface of carrier are clean and free of burrs, then apply a film of oil to these surfaces. Support carrier on suitable blocks and install several pinion pins to serve as pilots, then place turbine in position so that carrier is squarely started into recess in turbine.

2) Use a hammer and hardwood dowel to tap turbine down over carrier. *CAUTION - Use light blows midway between holes and alternate from sid to side of carrier to keep parts square with each other and to avoid distortion. If carrier and turbine cannot be assembl d with moderate force, separate parts and check for burrs in counterbored recess.*

3) With turbine and carrier supported on blocks, hub side down, assemble and install four pinions as follows: With planet pinion on a thrust washer, install 22 needle bearings in pinion and place a thrust washer on top of pinion. *NOTE - A loading tool for this purpose can be made from a piece of steel rod(3/8" diameter by 11/16" long).* Place assembled pinion in carrier and install a

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (Cont.)

pinion pin with notched end up. After loading tool is pushed out of carrier, slide a block under pinion pin to hold it in place. Turn all pins so that notches face center of carrier.

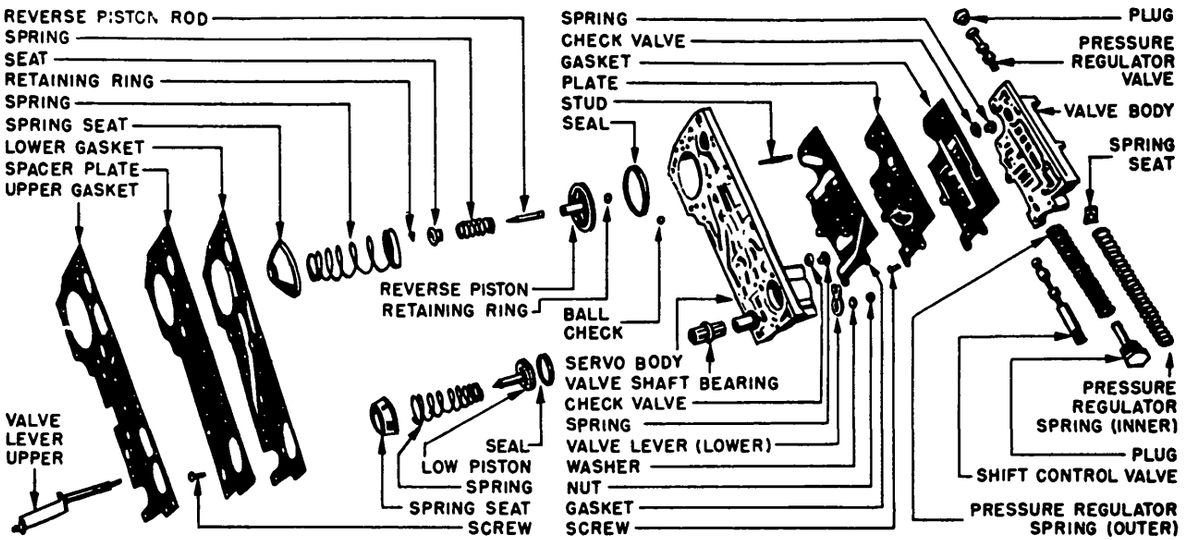
4) Install pinion pin lock plate so it enters notches of all pins, then install the four turbine-to-carrier bolts and lockwashers and tighten securely. Install sprag in bore of sun gear with shoulder out, then carefully press bearing in place. *NOTE - The sprag for the sun gear has a copper colored cage while the first stator sprag has a plain steel cage. DO NOT interchange these parts.*

5) Check operation of sun gear sprag clutch by sliding sun gear assembly on reaction shaft with gear end toward front of transmission. When viewed from front of transmission, sun gear must rotate freely clockwise and lock in counterclockwise direction. Place tanged thrust washer in second turbine carrier and install sun gear in second turbine assembly.

6) Place a tanged thrust washer on forward face of second turbine carrier. Hold in place with chassis lubricant, then lower second turbine assembly into first turbine support and ring gear assembly.

7) Lay first stator on bench with thick edge of blades up, then place first stator sprag in hub of first stator with shoulder up. Install one bronze bearing and one cupped thrust washer on each side of sprag. *NOTE - Sprag for first stator has a plain steel cage while sun gear sprag has a copper colored cage. DO NOT interchange thes parts.*

8) Check operation of first stator sprag clutch by sliding stator on reaction shaft with thin edges of blades toward front of transmission. Stator must turn freely clockwise and lock in counterclockwise direction when viewed from front of transmission.



9) Lower first stator assembly into turbine support on top of second turbine assembly with wide edge of blades up. Place first turbine in position on turbine support paying particular attention that turbine is assembled in its original position. *CAUTION - Turbine and support are balanc d as an assembly.* Carefully drive turbine down into position by tapping with a wooden block, making sure that roll pin holes are lined up.

10) Use a pair of channel lock or other suitable pliers to force roll pins into engagement with first turbine support roll pin holes. Roll pins should not extend outside support more than 1/32".

1954-60 MODELS

VALVE & SERVO BODIES: Disassembly (Valve Body) - Remove lower valve operating lever and linkage adjusting lever from upper lever shaft. Remove safety nuts and washers from studs, then lift valve body and gasket from servo body. Remove shift control valve from valve body. Remove rear pump delivery check valve and spring from servo body, then remove the large pressure regulator valve plug from valve body. *CAUTION - There is heavy spring pressure behind plug.* Remove the two springs and spring seat. Remove small plug and remove pressure regulator valve from body. Remove valve body gasket, then remove front pump delivery check valve and spring.

Disassembly (Servo Body): Remove servo body spacer plate attaching screw at reverse servo which is in line with low servo, then place a 1"x1"x13" wooden

VARIABLE PITCH DYNAFLOW VALVE & SERVO BODY ASSEMBLY

block across the low and reverse servo spring seats. Hold block down firmly while removing the remaining spacer plate attaching screws, then carefully release pressure on block to allow servo springs to expand. *CAUTION - This operation must be done carefully to avoid springing the spacer plate or letting the servo springs fly out.* Remove low and reverse servo piston spring seats, springs and pistons. Remove check ball from reverse servo feed channel.

Inspection: Wash valve and servo bodies and parts with clean solvent and blow dry with air. Inspect bodies for cracks, damaged gasket surfaces, and scored piston and valve cylinders. Inspect valves and pistons for nicks, scores, scratches, or rounded shoulders (edges must be kept sharp to keep out foreign material which would cause sticking). Replace worn or damaged piston seals.

►*PISTON SEAL INSTALLATION CAUTION: Lip on seal must fit over SMALLER diameter land on piston.*

Reassembly (Servo Body): Oil and install low and reverse servo piston assemblies in servo body. *NOTE - To avoid curling or damaging edge of piston seal, start each piston into cylinder at an angle, then turn piston as it is straightened and pushed into cylinder.* Check pistons for free movement in cylinders. Install small return spring against low servo piston, then install large return spring with the large end against reverse servo piston. Place spring seats on upper ends of both springs. Place check ball in reverse servo feed channel. Install a new spacer gasket and place spacer plate in position over spring seats. Place the same wooden block used at removal across spring seats to compress springs while installing spacer plate screws. Tighten screws uniformly to avoid distorting spacer plate.

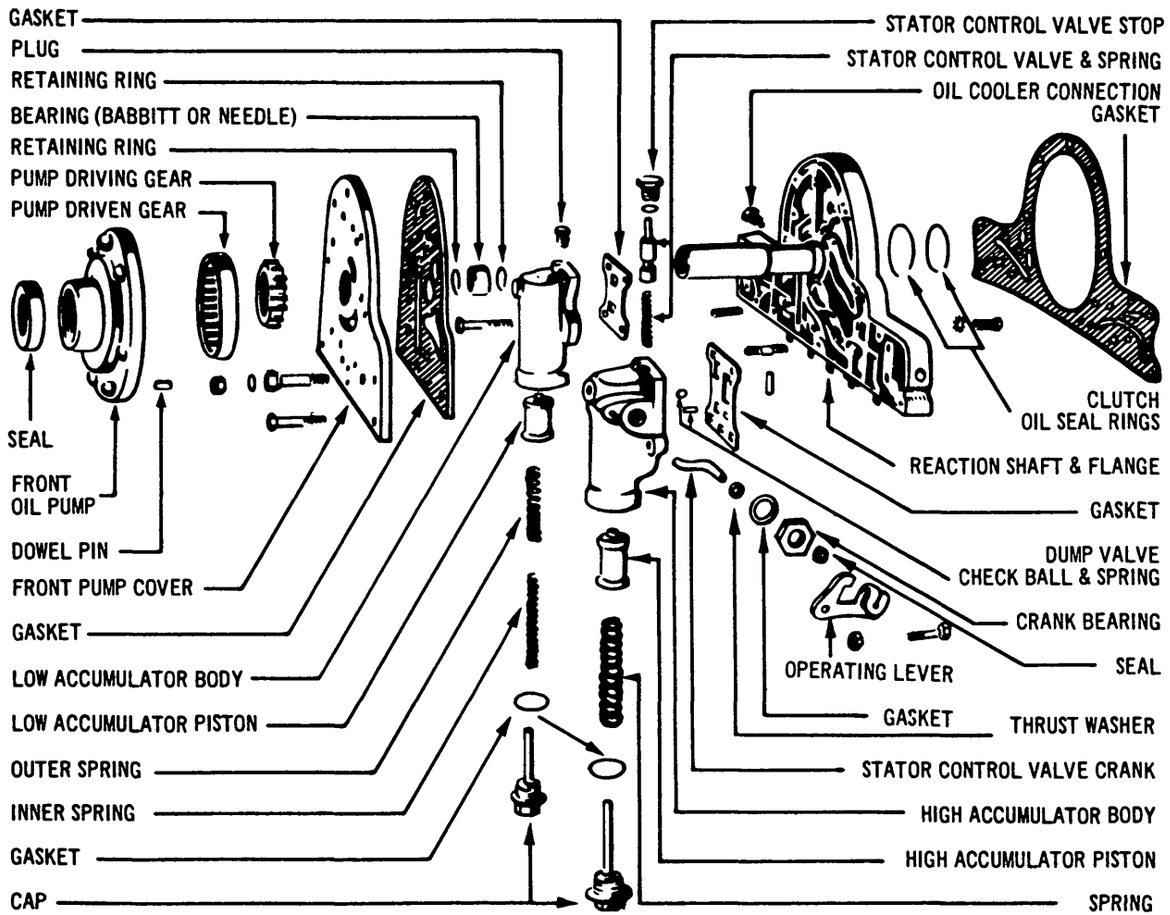
Reassembly (Valve Body): Place front pump delivery check valve spring in body with large end down and place check valve on spring with ridged side up. Install valve body plate and a new gasket, making sure that check valve is seated against plate and not caught under gasket. Place pressure regulator valve spring seat on inner spring, then install spring seat, inner and outer springs, and the large plug in valve body. Tighten plug to 20-25 ft. lbs. Install shift control valve with slotted end on same end of valve body as large pressure regulator plug. Install rear pump delivery check valve in its seat in servo body, ridged face inward, and place valve spring on valve with large end up. Install a new gasket and the valve body on servo body, using care to keep pump delivery check valve spring below the gasket, then install plain washers and safety nuts on two studs adjacent to control valve. Tighten stud nuts evenly to 11-15 ft. lbs. Insert valve operating upper lever shaft through bearing in servo body. With upper lever pointing toward reverse servo, place lower lever with linkage adjusting lever on shaft so that forked end of lower lever engages shift valve pin, then install lockwasher and nut.

REACTION SHAFT FLANGE & OIL PUMP: Disassembly - Remove high and low accumulators from reaction shaft flange. *CAUTION - Be careful not to lose retaining pin and check ball from high accumulator.* Inspect input shaft bushing in front end of reaction shaft. If bushing is damaged or excessively worn, remove outer retaining ring and remove bushing, using Tool J-5822 and a slide hammer. *NOTE - Oil pump must be in place to support reaction flange during bushing removal.* If inner retaining ring remained in place in shaft make sure it is firmly seated in its groove; otherwise replace it. Remove front oil pump body and gears, tapping body lightly with mallet to free it. Remove front oil pump cover and gasket from reaction shaft flange. If the ball check located in clutch feed passage of reaction shaft flange is free to drop out, remove ball. *NOTE - Do not remove if securely retained by peened edge of hole.*

Inspection (Front & Rear Oil Pumps): Wash parts in solvent and dry thoroughly, then check mounting faces of bodies, gears, front pump cover and rear pump cover plate for excessive wear. Inspect front pump bushing. If bushing is loose or excessively worn, replace pump assembly. *CAUTION - If front pump bushing is loose or*

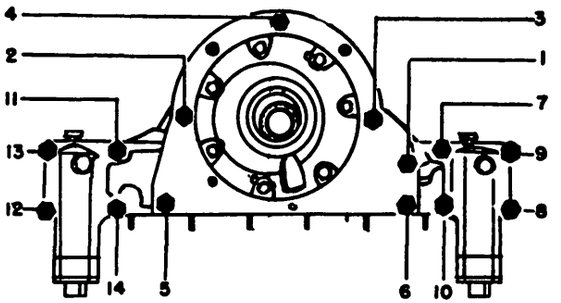
CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)



excessively worn, or pump was noisy, check for flywheel run-out, converter pump hub run-out, and misalignment of converter housing. Inspect front pump oil seal but replace it only if there is definite evidence of leakage or damage. To replace, drive out seal with a punch. Lightly coat new seal with Permatex No. 3, then start seal squarely into pump body with deep groove in seal retainer outward and tap into place with hardwood block and mallet. Remove excess Permatex.

Pump Gear End Clearance Check (Front & Rear Pumps) - Mount dial indicator on J-1013 (support), and place support on pump body so indicator button bears on body, then set indicator to zero. Rotate support and indicator, keeping support on pump body and indicate each pump gear. Indicator reading for front pump should be .001-.0025" and rear pump .001-.002". Insert a feeler gauge between crescent and **driven** gear to check clearance which should be .005-.009" on front pump and .0045-.007" on rear pump. Insert feeler gauge between crescent and **driving** gear to check clearance which should be .010-.016" on front pump and .006-.012" on rear pump. Check front pump cover and rear pump cover plate for depth of wear caused by gear. Replace part if depth of wear exceeds .001" or if surface is scored.



Inspection (Reaction Shaft Flange): Wash in solvent and blow out all passages, then dry thoroughly. Inspect surface of flange and transmission case for nicks or burrs and remove with a mill file. Inspect race for clutch drum roller bearings on rear end of reaction shaft. If bearing surface is worn excessively or scored, replace reaction shaft flange. *NOTE - If flange is replaced, stamp transmission identification number in lower edge of new part in same place as on original flange.* Check all studs for tightness and replace any with damaged threads. *NOTE - If stud threads are stripped in reaction flange, tap out hole for installation of "step studs". The 5/16" - 18 "Step studs" have a 3/8" - 16 thread on flange end, while the 3/8" - 16 "step studs" have a 7/16" - 14 thread on flange end.* Inspect oil sealing rings on hub of flange and replace if damaged.

Reassembly (Reaction Shaft Flange & Oil Pump): If old input shaft bushing was removed, make sure that inner retaining ring is firmly seated in groove in reaction shaft, then install a new bushing with Tool J-5816. Support shaft on wooden block and drive bushing into place with a light hammer until shoulder of tool con-

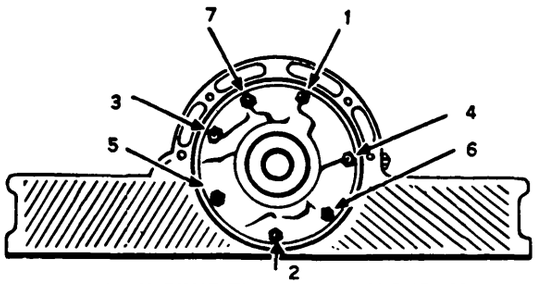
VARIABLE PITCH DYNAFLOW REACTION SHAFT FLANGE, ACCUMULATORS, & FRONT IL PUMP ASSY.



REACTION SHAFT FLANGE & ACCUMULATOR BOLT TIGHTENING SEQUENCE (1954-60)

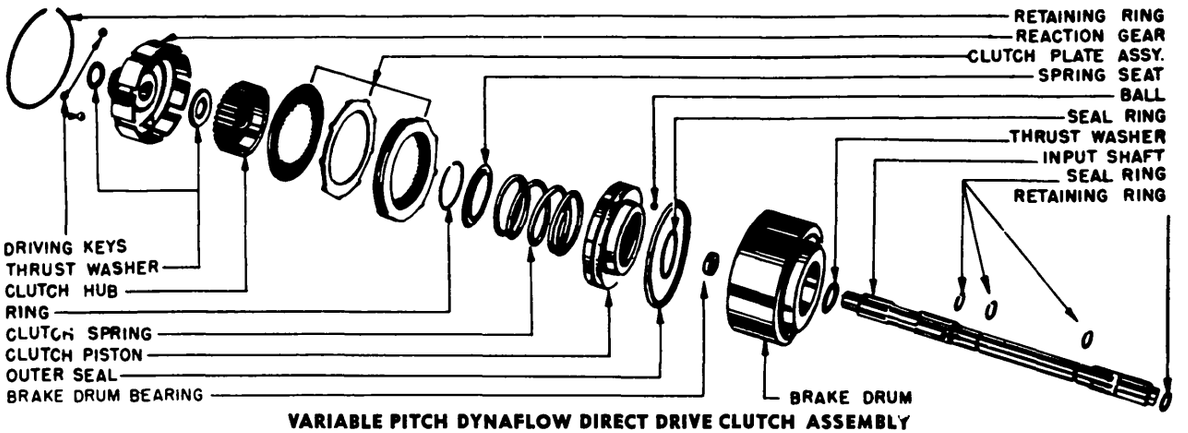
1954-56 VALVE & SERVO BODY BOLT TIGHTENING SEQUENCE

1957-60 VALVE & SERVO BODY BOLT TIGHTENING SEQUENCE

FRONT IL PUMP TI HTENIN SEQUENCE

DYNAFLOW DRIVE (C nt.)

tacts reaction shaft. Install outer retainer ring. Install check ball in clutch feed passage if ball was removed, then install a new gasket and pump cover on reaction shaft flange. Lubricate and install gears in front pump body. *NOTE - Driving g ar must be installed with bev l d sid outward so it will be against cover when pump is install d. R v rsing this gear will damage transmission.* Install oil pump on cover so the two dowel pins and bolt holes line up with holes in cover, then install bolts with lockwashers and tighten to approximately 5 ft. lbs. in proper sequence (see illustration) and then tighten in same sequence to 25-30 ft. lbs. Bend a tang of each lockwasher up against flat of bolt head. Tighten cover attaching nut stud to 25-30 ft. lbs.



ACCUMULATORS: Disass mbly - Remove retaining pin and check ball from high accumulator (low accumulator does not have check ball). Remove pipe plug, cap, gasket, spring (2 in low accumulator) and piston from each accumulator body. *CAUTION - Keep parts separated so sam parts will be reinstalled in same accumulator body.* On high accumulator only, remove clamp bolt, lever, bearing with seal, gasket, thrust washer and control valve crank from body, then remove valve stop with gasket, control valve and spring.

►*1954 ACCUMULATOR DISASSEMBLY NOTE: Variable pitch stator control valv crank assembly (referred to abov) is not used on 1954 models.*

Insp cti n: Wash all parts in clean solvent and dry thoroughly, then blow out all passages with air. Examine all parts of each accumulator for excessive wear, scoring, or other damage. Remove all nicks and burrs from pistons or valves with an Arkansas stone. Be careful not to round the sharp edges of lands on pistons and valves. With parts clean and dry, install pistons and check for free sliding as body is tipped back and forth. Check mounting surfaces of body with a straight edge. *NOTE - If surface is uneven it may b tru d up by moving body in a circular motion over em ry cloth placed on a surface plate. Be sure to rem v all traces of m ry.* If body or piston is worn or damaged, or piston does not slide freely in body after all burrs are removed, replace accumulator assembly. *NOTE - Th body and piston are not furnished separat ly for s rvic r plac ment.*

K ass mbly: Lubricate each piston and install it in accumulator body from which it was removed. *CAUTION - Start piston squar ly into body. DO NOT tap or force it into body.* Install proper piston springs in each body. The high accumulator uses one heavy spring approximately 4 5/16" long. The low accumulator uses one short heavy spring and one inner spring. Install caps with new gaskets. *NOTE - Caps will be tightened lat r. DO NOT clamp accumulator in a vise to tighten cap.* On high accumulator only, install spring, control valve and stop, then install crank with thrust washer, bearing with new gasket and seal (grooved side inward), operating lever and clamp bolt. Adjust operating lever on crank so that lever contacts stop and the crank contacts valve with valve in extreme upper position, then tighten clamp bolt. Install pipe plugs in both accumulators and install check ball and retaining ring in high accumulator body.

MULTIPLE DISC CLUTCH: Disass mbly - Remove reaction gear flange retainer ring, then remove the six

VARIABLE PITCH DYNAFLOW DIRECT DRIVE CLUTCH ASSEMBLY

flange driving keys with a pointed tool. Remove low range reaction gear, thrust washer, clutch hub, and 12 clutch plates from drum. Install spring compressor Tool J-2590 in drum, placing slots in compressor ring over ends of spring seat retaining ring. Compress clutch spring sufficiently to remove retaining ring. Release pressure on clutch spring, making sure that spring seat does not engage retaining ring groove in drum, then remove spring compressor, spring seat, and spring. Remove piston from drum. If necessary, rap open end of drum against a block of wood to remove piston.

Inspection: Wash all parts in solvent and dry thoroughly. *CAUTION - Use only gasoline or kerosene to clean clutch plates and bands.* Inspect all plates and replace any that are scored, burned, warped or worn excessively. Check fit of any new internally splined plates on clutch hub to make sure they slide freely on hub. Inspect the clutch drum for cracks or scores. Inspect clutch drum seal and replace if damaged. Inspect clutch edges. Install a new seal with lip extending over smaller diameter land of piston. Make sure that small bleed hole in drum is open and that ball check is staked in place but free to move in recess. If needle bearing in drum is worn or scored, carefully remove it and install a new one with Tool C-5191. *NOTE - This tool will locate bearing flush with shoulder.* Place numbered end of bearing, which is hardened, toward shoulder of tool to avoid distortion of cage. Inspect low band and replace if grooves in band are not visible. Inspect input shaft splines, bearing surfaces and oil seals. Replace if necessary.

Reassembly: Apply light oil to piston outer seal and inside of drum, then install piston being careful to avoid distorting or turning lip of seal. When piston is fully installed in drum, top of piston will be approximately flush with shoulder on inside of drum. Place clutch spring in piston and place spring seat and seat the retaining ring on the spring. Install spring compressor, Tool J-2590, and compress spring until the retaining ring can be snapped into groove in hub of drum, then remove spring compressor. Place reaction gear on bench with flange upward, then install clutch hub thrust washer and clutch hub over hub of reaction gear with open end of clutch hub facing up. Separate internally splined (faced) clutch plates from externally splined (steel) clutch plates. *NOTE - Internally splined teeth plates are flat and may be installed in either direction. Externally splined plates are "dished" and all these plates must be installed with "dish" in same direction. "Dish" may be either up or down.* Check each plate for "dish" with a straight edge and stack so they are all "dished" in same direction. Install an internally splined clutch plate over clutch hub, next to gear flange, then install an externally splined plate. Alternately install remaining plates, making sure "dished" plates are installed in the same direction. If properly installed, top plate will be externally splined. Place drum and clutch piston assembly over reaction gear flange so that driving key recesses in drum and flange are approximately aligned, then press drum evenly into place over reaction gear flange. Complete alignment of driving key recesses by tapping the reaction gear flange, then install 6 driving keys and reaction gear flange retainer ring.

REAR BEARING RETAINER, TORQUE BALL & UNIVERSAL JOINT: Disassembly - Remove spring from detent roller lever and support inside the rear bearing retainer, remove adjusting lever on outside of retainer, then remove lever and support assembly. Disconnect parking brake lock operating rod from cross shaft by by unscrewing rod from lever. Push clip from valve operating rod to remove clip and rod from cross shaft. Screw a ¼" - 20 bolt into parking lock operating lever shaft and lock pawl shaft and pull these parts from bearing retainer, then remove lock pawl and lever assembly. Remove cross shaft bearing. *CAUTION - Us a box wrench. A socket which does not fully engag bearing, or an end wrench will distort bearing.* Remove cross shaft.

Inspection: Inspect valve operating cross shaft and bearing for excessive wear (remove rubber seal from bearing and discard it). Inspect bearing for roughness or wear. Inspect lock pawl and ratchet wheel for cracks and worn teeth. Inspect universal joint for wear and play. Check fit of universal joint yokes on output shaft and propeller shaft. Allowable backlash of rear yoke on propeller shaft is .0005-.0045". *NOTE - Front yok must be a tight fit rotativ ly on output shaft to prevent "snap".* Inspect rear yoke of universal joint.

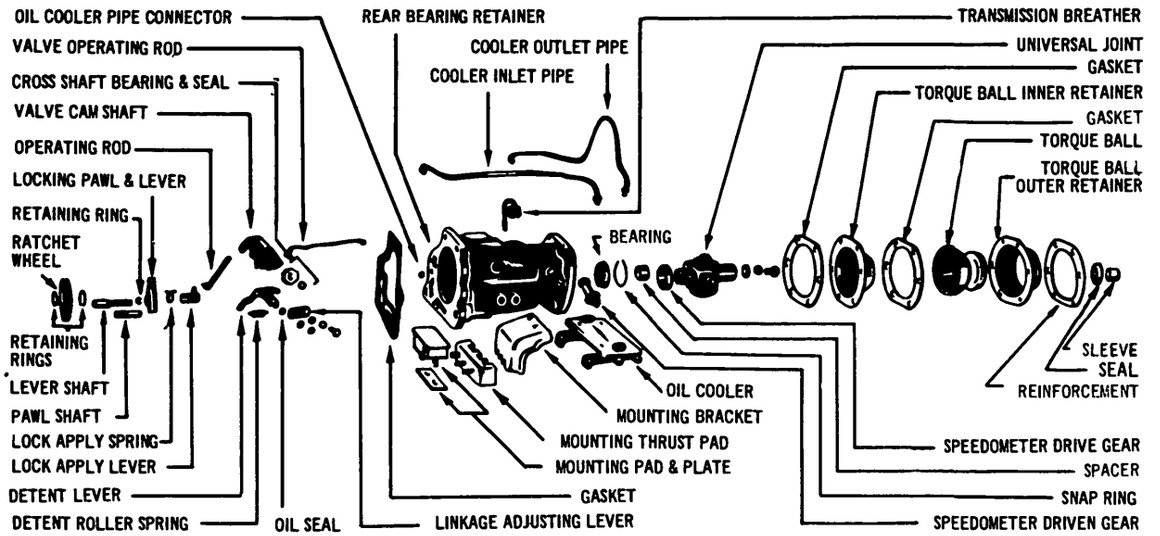
CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

Rear yoke and bushing in torque ball must be free of scores and not worn excessively. Clearance between these parts should be .004-.006". Clean and inspect spherical surfaces of both retainers and rubber on torque ball. If these are scored, pitted, or torn, replace as necessary.

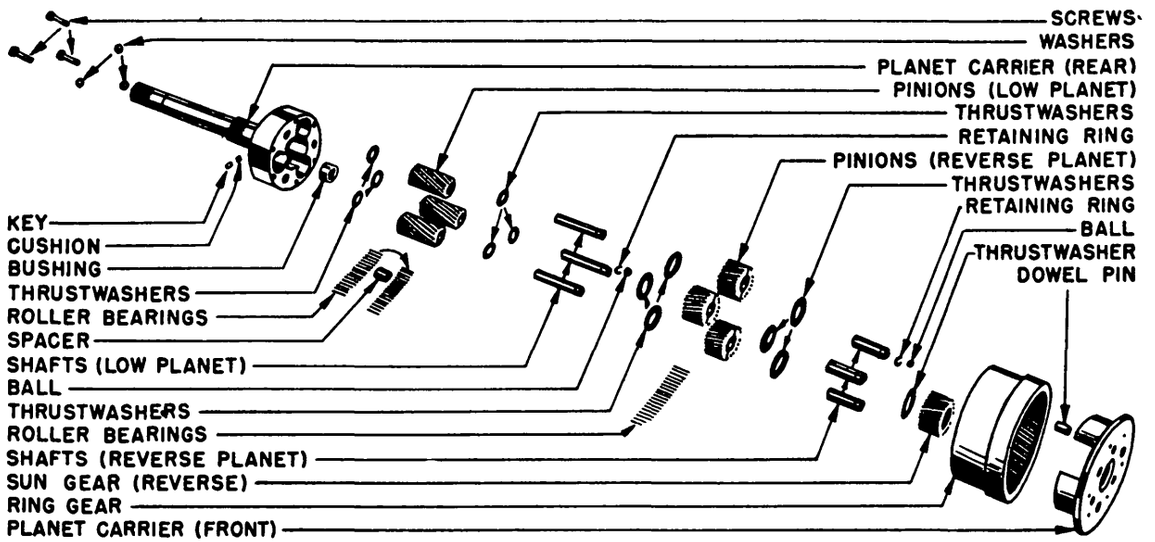
Reassembly: Install valve operating cross shaft and cross shaft bearing. Install a new seal in bearing with grooved side facing inward. Install parking lock pawl and lever assembly in rear bearing retainer, then install lock pawl shaft and operating lever shaft with tapped ends outward. Attach valve operating rod with retainer clip to cross shaft lever and snap clip into place on rod. Connect parking lock operating rod to cross shaft lever, using a lockwasher on threaded rod end. Install detent lever and support assembly with new seal in groove of shaft, then install linkage adjusting lever on shaft with nut and lockwasher. Attach adjusting lever to bearing retainer with bolt, plain washer and lockwasher, but do not tighten until detent adjustment is made. Temporarily install shaft lever on cross shaft and shift parking pawl into "P" (Park) position. Shift the linkage adjusting lever at slotted end until pawl lock contacts parking pawl, then tighten adjusting lever lock bolt, being sure to maintain contact between lock and pawl. Move shift lever back and forth to check detent adjustment. Parking lock must contact parking pawl when detent roller is in deepest portion of parking notch of detent lever and should break contact at same instant that detent roller starts to move toward neutral position.

PLANETARY GEAR SET: Disassembly - 1) Remove three planet carrier screws and special lockwashers (use 7/32" Allen wrench). *NOTE - A used universal joint yoke may be placed on output shaft and held with a bar while removing the screws.* Separate front and rear ends of carrier by tapping around front flange while holding unit clear of bench.



2) Remove sun gear thrust washer (may be either on sun gear or stuck in rear end of carrier), then remove reverse sun gear and needle thrust bearing.

3) Remove the three low planet pinion assemblies, each consisting of a pinion, shaft, and bearing rollers retained at each end by steel thrust washers. A retaining ring snapped into a groove in shaft will hold lower thrust washer in place as the shaft is tapped out of carrier. *NOTE - The shaft is prevented from turning in carrier by a 3/32" steel ball imbedded in end of shaft. Do not lose the steel ball.*



4) Remove the three reverse planet pinion assemblies in the same manner as for low planet pinion assemblies.

5) Remove thrust washers and shafts from pinions, then remove bearing rollers. *NOTE - Reverse planet pinions have a single set of rollers while low planet pinions have two sets of rollers separated by a spacer.*

Inspection: Wash all parts in solvent and dry thoroughly, then carefully inspect shaft and rollers for excessive wear. Inspect reverse ring gear, sun gear, and pinions for wear. Remove any nicks or burrs with Arkansas stone. Inspect bushing in rear end of planet carrier and replace if worn or scored. Use Tool J-3197 to remove bushing and Tool J-2996 to install new bushing. Reaming to size is not necessary and bushing can be installed with either end first. Inspect reverse band and replace if cracked or if lining is worn so that grooves are gone. Inspect band anchor for cracks.

VARIABLE PITCH DYNAFLOW REAR BEARING RETAINER & TORQUE BALL ASSY.

VARIABLE PITCH DYNAFLOW TRANSMISSION PLANETARY ASSEMBLY

Reassembly: 1) Reassemble planet pinions and shafts with bearing rollers and thrust washers. *NOTE - The bottom thrust washer goes between retaining ring on shaft and end of pinion. Each reverse planet pinion contains 24 rollers. Each low planet pinion contains 20 rollers separated by a spacer.* Place a thrust washer on upper end of each assembly to hold rollers in place. Make sure that steel ball is embedded in each shaft to prevent turning in carrier, then install planet pinion assemblies in front end of planet carrier using care to engage steel balls in notches in carrier.

2) Install reverse sun gear and place bronze thrust washer on top of gear and needle thrust bearing on bottom of gear (toward front of transmission).

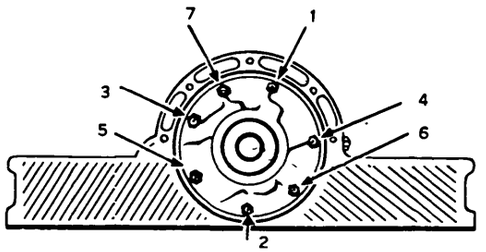
3) Install rear end of planet carrier on assembled front end making sure that assembly marks on both parts are in alignment. *NOTE - These marks are numbers which are placed over the parting line during production of carrier.*

4) Install the three screws with special lockwashers and tighten to 25-30 ft. lbs. Install reverse ring gear on planetary gear set.

TRANSMISSION CASE: Inspection - Wash case thoroughly and blow out all passages. Inspect case for cracks, breaks, and stripped threads in bolt holes. Inspect all

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)



machined surfaces for nicks or burrs and smooth off with a mill file. Inspect bushing for wear and scoring. Insert planet carrier into bushing and check clearance with feeler gauge. If clearance is excessive due to wear of bushing, replace bushing. To remove old bushing, place case over an opening with rear end down and drive bushing from case with Tool J-3175-1. To install new bushing, place Tool J-3175-2 in rear oil pump recess of case to serve as a pilot, slip bushing over Tool J-3175-1 and drive bushing into case from front side until bushing is flush with front surface of wall which supports bushing. *NOTE - Bushing must be installed with wide d ep ends of oil grooves toward rear sid of case.*

TRANSMISSION UNIT INSTALLATION

Plan tary Gear Set: Install reverse ring gear thrust washer in case, then compress ends of reverse band with band installing clip Tool J-2595, and install in case. *NOTE - When installing band make sure that heavy side of band is in correct position so that it will attach to reverse anchor and not to strut.* Remove clip, then rotate servo band toward servo opening. Insert anchor through opening and engage with hooked end of band, then rotate band and anchor back to normal position. *NOTE - Reverse band does not have strut locating pins in ends (low band has pins).* Hold band operating lever (with offset end) in place with strut shoulder toward inside of case and insert anchor shaft through case, anchor, and lever. *NOTE - Tapped end of shaft must be outward. If adjustment screw is not centered in servo opening, the low band operating lever has been installed by mistake.* Install assembled planetary gearset.

R ar Oil Pump & Lubrication Oil Pressure Regulator Valves: Place gasket and rear oil pump plate in re ess in transmission case and align the bolt holes (bolt holes not evenly spaced). Install oil pump drive key cushion (rubber) and drive key in output shaft, then install driving gear to engage key. *NOTE - Install old gear in same position as before removal. Install a new gear either way.* Lubricate both pump gears and pump body, then install driven gear and body over the driving gear and align bolt holes. Install pump bolts with lockwasher, tighten evenly to 5 ft. lbs. in sequence (see illustration), then tighten in the same sequence to 25-30 ft. lbs. Turn output shaft to make sure pump operates freely. Install lubrication oil pressure regulator valve spring, valve, and valve seat in transmission case.

R ar B aring Retain r, R ar Bearing & Parking Lock Ratch t Wheel: Install a retaining ring in forward groove in output shaft, install ratchet wheel, then install retaining ring in rearward groove in output shaft. Install rear bearing horseshoe washer on output shaft, then install rear bearing and rear bearing snap ring in retainer. Install rear bearing retainer and gasket on transmission case. Use lockwashers on attaching bolts and tighten bolts evenly to 25-40 ft. lbs.

FRONT OIL PUMP TIGHTENING SEQUENCE

Low Band, Clutch & Input Shaft: 1) Install low band operating lever and shaft. *NOTE - Strut shoulder of lever must be toward inside of case and tapped end of shaft must be outward.* With the assembly standing on end of rear bearing retainer, install a wooden block 1"x2"x3½" in case, then set both low band struts in position on block, with plain ends engaging strut shoulder of operating lever and groove in anchor shaft and with notched ends together and about 3/16" from wall of case. Spread struts as far as possible.

2) Compress ends of low band with installing clip, Tool J-2595, then install band in case with ends between struts resting on wooden block. Apply operating lever to hold struts and band, remove clips and block, then press down until locating pins engage notches in both struts.

3) Install a thrust washer that measures between .114" and .117" against needle thrust bearing. *NOTE - Reaction gear selective thrust washers (steel) of four thicknesses are available for service replacement.* Install clutch assembly. If drum binds against low band so that clutch does not go all the way down, use a hooked wire to lift band on side opposite struts.

4) Place bronze thrust washer on front face of clutch hub, then use a flashlight to make sure that all four thrust washers and needle bearings are centrally located so that input shaft can be inserted. With ends of input shaft oil seal ring properly locked, install input shaft. *NOTE - It may be necessary to wiggle input shaft to get it through all four thrust washers and needle bearing.*

1954 MODELS

Reaction Shaft Flange, Front Oil Pump, & Accumulator Installation: Install special guide pin (see Guide Pin Note below) in accumulator bolt hole at each end of flange on transmission case. Install new gasket over guide pins so that all holes in gasket and case aligned (*CAUTION*—gasket can be installed incorrectly). Check oil seal rings on reaction shaft flange for correct installation with ends locked, install flange using care not to damage these seal rings. Install low accumulator (on same side as low band operating lever), and high accumulator (opposite side) making certain that holes in gasket and flange match. Coat accumulator bolt threads lightly with Permatex #3, install bolts and nuts with lockwashers but do not tighten, remove guide pins. Install three special bolts (⅜"-16 x 2") with plain washers in #2, 3, 4 positions (see Tightening Sequence illustration) for assembly purposes (these bolts removed after assembly completed), install regular pump cover bolts, nuts, and lockwashers at positions #1, 5, 6 (*CAUTION*—Coat #5 bolt threads with Permatex #3). Tighten all bolts and nuts (1-14) to 5 ft. lbs. torque in sequence shown in the illustration, then tighten #1 through #4 to 35-40 ft. lbs. and all remaining nuts and bolts to 20-25 ft. lbs. torque in the same sequence. Remove the three special bolts (#2, 3, 4). Tighten accumulator body caps to 40-50 ft. lbs. torque. Check flange gasket and trim lower edge flush with bottom face of transmission case if it projects.

►Guide Pin N te—These 5/16" guide pins can be made up from 5/16" round stock, 2½" long, with 5/16"-18 thread ½" long on one end and screwdriver slot on opposite end (chamfer this end slightly).

1955-60 MODELS

Reaction Shaft Flange, Front Oil Pump & Accumulator Installation: Install 5/16" guide pin in accumulator bolt hole at each end of flange on transmission case, then proceed as follows:

1) Place reaction shaft flange gasket in position on case so all holes in gasket are aligned with holes in case. Install tanged bronze high clutch thrust washer on reaction flange, using chassis lubricant to hold in position. Make certain that oil seal rings are on flange hub, then install flange assembly on case using care to avoid damage to oil seal rings.

2) Install three special bolts (3/8"-16x2") with plain washers in positions marked 2, 3, 4 in "bolt tightening sequence" illustration. (*NOTE - These bolts are for assembly purposes only*). Install regular pump bolts and lockwashers at positions marked 1, 5, 6. Coat threads of No. 5 & No. 6 bolts with Permatex No. 3. *NOTE - Bolts used at No. 5 & No. 6 locations ar special bolts with captive sealing washers.* Tighten bolts marked 1, through 4 to 35-40 ft. lbs. and bolts 5 & 6 to 20-25 ft. lbs. in numerical sequence.

3) Thread Endplay Gauge J-5804 into rear end of output shaft and thread Extension Rod J-5808 into a bolt hole in rear bearing retainer. Tighten both tools firmly. Use Clamp KMO-30-G and Sleeve KMO-30-K to mount dial indicator KMO-30-B and Extension J-5339 so that extension bears squarely against end of Gauge J-5804. Push Gauge J-5804 as far forward as possible, set dial indicator at zero, then pull gauge rearward toward indicator with sufficient force to remove all endplay from output shaft. Note indicator reading which should be between .020" and .040" if output shaft endplay is within limits. If endplay not within limits, remove reaction shaft flange, clutch assembly, and the thrust washer located between reaction gear and reverse sun gear.

4) Measure thickness of removed thrust washer and substitute another of proper thickness to bring output shaft endplay within the above limits. *NOTE - If endplay is less than .020" select a thinner washer. If more than .040" select a thicker washer.* Reinstall parts and recheck for correct endplay. Place accumulator gaskets in position so holes match holes in reaction flange. Install low accumulator on same side as low band operating lever and install high accumulator on opposite side of flange, first making sure that check ball and retaining pin are in place in high accumulator body.

5) Coat accumulator bolt threads with Permatex No. 3 and install bolts and stud nuts with lockwashers, but do not tighten. *NOTE - "O" ring seal used under flat washer at No. 9 position.* Tighten all bolts and nuts (1 through 14) to 5 ft. lbs. in numerical sequence. Following the same sequence again, tighten bolts (1 through 4) to 35-40 ft. lbs. and the remaining bolts and nuts to 20-25 ft. lbs. Remove three special bolts (2,3,4) and tighten accumulator body caps to 40-50 ft. lbs. If edge of flange gasket protrudes beyond bottom surface of transmission case, carefully trim it flush with a knife.

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

1954-60 MODELS

Valve & Servo Body Assembly & Oil Pan: *NOTE - Valve body and shift control valve were changed in early 1957 production and the adjustment procedure for Late 1957-60 is different as indicated below. See "Late 1957-60 Shift Control Valve & Body Production Change Note & Adjustment Caution". For identification of later type parts, see "1957 Valve Body & Valve Production Change" above.*

Valve & Servo Body Assembly & Oil Pan: 1) With transmission lying bottom side up, raise reverse band operating lever and insert strut between shoulders on lever and end of band, with rounded ends against levers and band. *CAUTION - Do not lift the lever during following steps because band strut will fall into transmission.*

2) Install two 5/16" guide pins into case to guide each end of servo body and install servo body spacer plate gasket over guide pins. Push shift control valve and lower operating lever inward to align upper lever with opening in case and install valve and servo body on case. Engage pin in control valve with slot in operating lever.

►*GUIDE PIN NOTE: These 5/16" pins can be made up from 5/16" round stock, 2½" long, with 5/16"-18 threads ½" long on one end and screwdriver slot on opposite end. NOTE - Chamfer this end slightly.*

3) Install various length bolts with lock washers according to depth of holes through valve and servo bodies. *NOTE - Use copper washer on bolt No. 10 (1954), bolt No. 16 (1955-60). See tightening sequence illustration.* Tighten all bolts to 5 ft. lbs. in the numerical sequence indicated in tightening sequence diagram. Repeating the same sequence, tighten all ¼" bolts and nuts to 11-15 ft. lbs. and all 5/8" bolts to 15-20 ft. lbs. While tightening bolts and nuts adjacent to shift control valve, operate the valve to make sure it is not binding. *NOTE - It may be necessary to tighten some bolts to low limit of torque to prevent valve binding.*

4) Using Linkage Hook-Up Finger J-2591, position the socket of valve operating rod under ball of valve upper operating lever and pull upward until ball snaps into socket. Temporarily install shift lever on cross shaft and operate valve linkage to make sure it works freely. More lever toward front of transmission to engage parking lock pawl in ratchet wheel. Turn output shaft to make certain it is locked.

5) Move shift lever to direct drive position and note position of control valve. The groove in first land of valve should be flush with boss on valve body. If valve not positioned properly in valve body, loosen bolts attaching valve body to servo body and shift as required. *NOTE - Bolt holes permit some movement of valve body.* Tighten bolts to specifications *(see "Transmission Unit Overhaul" above).*

6) Spread a thin coat of Permatex No. 3 on transmission case only in area where case is cutaway under the oil pan gasket. *NOTE - This is adjacent to valve operating lever.*

7) Install a 5/16" guide pin *(see "Guide Pin Note" above)* at each end of transmission case and install a new oil pan gasket over guide pins. Install oil screen, then install oil pan and evenly tighten all bolts to 15-18 ft. lbs.

Universal Joint, Torque Ball & Speedometer Driven Gear: On 1954-55 models, make certain that joint retaining ring is fully seated in groove of output shaft before installing universal joint. Install plain washer, lockwasher, and bolt, and tighten bolt to 30-35 ft. lbs. *CAUTION - Make sure that oil passage in bolt is clear.* Install speedometer driven gear and sleeve assembly in rear bearing retainer. On later models, install speedometer driven gear, then install universal joint. Move shift lever to park position and install universal joint bolt, flat washer, and lockwasher, then tighten bolt to 50-55 ft. lbs. *CAUTION - Make sure that oil hole in bolt is clear.*

Torque Ball Installation & Adjustment (1954-55 Models): *See "Torque Ball Adjustment" in Buick Special Data in Car Model section.*

1954 MODELS

Bell Housing & Torque Converter Assembly Installation:

1) Install front oil pump seal ring around pump body against pump body. Install bell housing, using lockwashers on bolts and stud. Sparingly coat threads of lower right side bolt with Permatex #3 (bolt hole opens into transmission case). Tighten bolts and stud nut evenly to 35-40 ft. lbs. torque.

2) Install converter pump on reaction shaft, turning it until lugs on pump hub enter the slots in front oil pump driving gear. Make sure that the ball bearing is properly seated in converter stator, then install this unit on reaction shaft while pushing against the roller race to keep it from sliding out of place. Install stator retaining ring in groove in reaction shaft.

3) Install sun gear on input shaft and mesh it with free wheel cam in stator, then install bronze thrust washer on shaft. Place second retaining ring in groove in shaft, using Expander J-5338-2 on end of input shaft, and Driver J-5338-1 to push retaining ring over end of shaft.

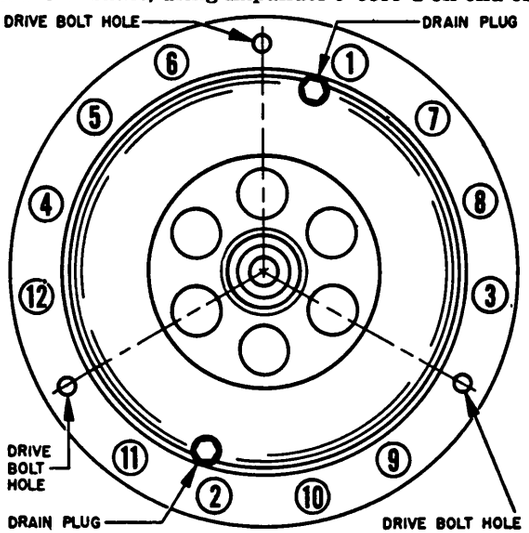
4) Support twin turbine assembly so that all weight rests on a block placed under center of second turbine.

5) Attach Extension J-5339 to plunger of Dial Indicator KMO-30-B, then mount indicator on Support J-1013 with Sleeve KMO-30-K. Place indicator support on the protruding hub of turbine carrier, adjust dial indicator so that extension bears against ground surface on first turbine hub, then SET DIAL INDICATOR AT ZERO.

6) Support converter pump cover on blocks in a horizontal position, lightly tap the input pilot bearing down against shoulder in hub of cover, and place a bronze thrust washer in recess at center of pump cover.

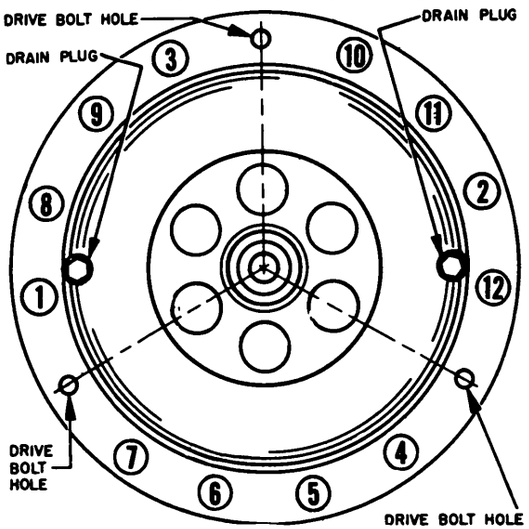
7) Remove dial indicator and support from turbine assembly and set it firmly on the thrust washer on pump cover so that indicator plunger extension bears against inner race of pilot bearing. ***CAUTION —use care to avoid changing the zero setting of dial indicator.***

8) The dial indicator should read between .002" and .010" CLOCKWISE from ZERO because the distance measured in Step 7 must be .002" to .010" LESS than the distance measured in Step 5. This difference is required to give the first turbine proper endplay or operating clearance in its position between the pump cover and second turbine.



9) If indicator does not read within specified limits, select another washer of proper thickness, which are furnished in the following sizes:

Thrust Washers



Part No.	Thickness	①Marked
1318799	.052-.055"	5
1318458	.060-.063"	6
1161654	.068-.071"	7

①—Thrust washer marked on flat surface.

CONTINUED ON NEXT PAGE

1954-56 CONVERTER PUMP COVER TIGHTENING SEQUENCE

1957-60 CONVERTER PUMP COVER TIGHTENING SEQUENCE

DYNAFLOW DRIVE (Cont.)

10) Install twin turbine assembly on output shaft, turning it as required to mesh planet pinions with sun gear.

11) Looking at front face of converter pump cover, select the three bolt holes that are aligned with the center of the hub and one of the counterbored recesses adjacent to hub (see illustration). Mark these holes for later installation of flywheel-to-pump driving bolts.

12) Install a new O-ring seal on pump cover, making sure that surfaces are clean and that seal has even tension all around and is not twisted.

13) Grease the selected thrust washer so it will adhere and place it in recess in cover, then install cover on pump so that the three marked driving bolt holes are not aligned with any hole in pump rim at which a balance weight is located.

14) Install bolts with plain washers and special nuts in all but the three driving bolt holes, insert shank of a 11/32" drill through one bolt hole to align all holes, then tighten bolts approximately 5 ft. lbs. torque in numerical sequence shown in illustration. Finally tighten bolts in same sequence to 25-30 ft. lbs. torque.

►***CAUTION—When tightening bolts, insert a wide screwdriver blade between flat side of bolt head and pump to prevent a corner of bolt from digging into pump casting.***

15) Screw the socket setscrew with lockwasher into input shaft through opening in pump cover hub.

16) Remove reverse band adjustment cover and shift into "P" (Parking). Pry up on reverse band operating lever with screwdriver to lock input shaft then tighten socket setscrew to 25-30 ft. lbs. torque. Install large hex plug with gasket in hub of pump cover and tighten securely. Install adjustment cover and gasket.

1955-60 MODELS

Bell Housing & Torque Converter Assembly Installation: 1) Install front oil pump seal ring around pump body against pump cover. Install bell housing, using lockwashers on bolts and stud. Sparingly coat threads of lower right side bolt with Permatex No. 3 (because bolt hole opens into transmission case). Tighten bolts and stud nut evenly to 35-40 ft. lbs.

2) Support converter pump firmly on blocks and carefully place stator in proper position, with original selective spacers and the thrust washer between stator and pump hub. ***CAUTION—Do not use grease to hold spacers in place.***

3) Place sun gear on stator with tanged thrust washer up, then carefully lower twin turbine assembly into place, making sure that planet pinions enter and mesh properly with sun gear. Install Converter Gauge J-5899 on converter pump flange, making sure that indicator post does not contact turbine. Loosen wing screw, firmly press gauge plunger down against first turbine hub and tighten wing screw.

4) Support converter pump cover firmly on blocks with inner side up and place bronze thrust washer in its recess. Remove Gauge J-5899 from pump, invert it, and center it on cover so that it rests squarely on the gasket surface.

5) Use Sleeve KMO-30-K to mount dial indicator KMO-30-B on the adjustable post of clearance gauge so that indicator button bears squarely against upper end of clearance gauge plunger.

6) Loosen plunger wing screw, firmly press plunger down against the thrust washer and note dial reading. The dial reading is clearance that will exist between turbine pump and pump cover when parts are installed, and should be .018-.029". If dial reading not within specified limits, change the total thickness of selective spacers located under the stator. *Increasing* spacer thickness will *decrease* clearance at cover and *decreasing* spacer thickness will *increase* the clearance.

Part No.	Spacers Thickness
1167710	.013-.010"
1167711	.023-.020"
1167712	.033-.030"

7) Install converter pump on reaction shaft, turning it until lugs on pump hub enter slots in front pump driving gear. Coat selective spacers and thrust washers with petroleum jelly so they will adhere to stator during installation. Make sure that all rollers and springs are in place and held in stator with tool J-5806.

8) While holding thrust washers and spacers to rear side of stator, slide stator off of installing tool onto the reaction shaft. Make certain that washer and spacers remain in place as stator is pushed back against converter pump. Install converter sun gear with the tanged thrust washer outward. If sprag is properly installed, the sun gear may be turned on reaction shaft in clockwise direction only.

9) Make sure that retaining ring is seated in groove of input shaft, then install the twin turbine assembly, turning it as required to mesh planet pinions with sun gear. Install selective thrust washer, retaining washer and bolt, with external tooth lockwasher on front end of input shaft. Shift into "P" (parking) and pry up on reverse band operating lever with a screwdriver to lock input shaft, then tighten bolt to 30-35 ft. lbs.

10) Check clearance between selective thrust washer and first turbine hub, using feeler gauges. Clearance should be .002-.009". If clearance not correct, substitute another thrust washer of proper size. Two sizes furnished for selective fitting (Part No. 1166113, .063-.060". Part No. 1166112, .070-.067").

11) Looking at front face of converter pump cover, select the three bolt holes used for pump to flywheel drive bolts (see illustration). Install a new "O" ring seal on pump cover, making sure that surfaces are clean and that seal has even tension all around and is not twisted.

12) On 1955 & 1956 Models, grease the selected thrust washer so it will adhere and place it in recess in cover, then install cover on pump so that the three marked driving bolt holes are not aligned with any hole in pump rim at which a balance weight is located. Install bolts with plain washers and special nuts in all but the three driving bolt holes, insert shank of an 11/32" drill through one bolt hole to align all bolt holes, then tighten bolts to approximately 5 ft. lbs. in numerical sequence (see illustration). Finally tighten bolts in same sequence to 25-30 ft. lbs. *NOTE - When tightening bolts, insert a wide screwdriver between flat side of bolt head and the pump to prevent a corner of the bolt from digging into casting.*

13) On 1957-60 Models, proceed as follows: Looking at front face of cover, turn converter cover so that drain holes are horizontally aligned, with seven bolt holes above a line through the drain plugs and eight bolt holes below (see illustration). In this position, the top center hole is a driving bolt hole as is the fifth hole from top in both directions. Mark these holes for later installation of flywheel-to-pump driving bolts. *NOTE - With converter in the above position, the triangular flywheel must be turned so that wide flange is down and horizontal to match converter driving bolt holes and clear drain plugs.* Install a new "O" ring seal on pump cover, making sure that seal has an even tension, is not twisted, and that all surfaces are clean. Grease selected thrust washer and install in recess in cover, then complete installation as outlined for 1955-56 models above.

ALIGNMENT

►*ALIGNMENT NOTE: Make the following alignment and runout checks if front pump is noisy, bushing and oil seal worn, or if oil leakage noted at Converter or Front Pump Body.*

Flywheel Runout: Mount a dial indicator on flywheel housing so stem of indicator rests against flat surface of flywheel at inner side of the bolt holes. Turn flywheel, making sure that crankshaft end thrust is held in one direction, and note runout of flywheel face which should not exceed .015". If runout exceeds .015", attempt to correct by tapping high side of flywheel with a mallet. If this does not correct runout, remove flywheel and check for burrs between flywheel and face of crankshaft flange, remove burrs, then recheck runout. If no burrs exist, install a new flywheel and recheck runout. If runout still exists, and is greater than .015", check runout of rear face of crankshaft flange.

Primary Pump Hub Runout: With converter primary pump and bell housing installed, mount dial indicator on bell housing so that it bears against primary pump hub. If runout exceeds .012" when flywheel turned, mark flywheel and primary pump, then remove and reinstall pump at a point 180° from first position. If pump runout still exceeds .012", install new primary pump and recheck runout. When a position is found where runout is less than .012", mark flywheel and pump with paint and align these marks when transmission is finally installed.

Bell Housing: Mount dial indicator on oil pump driving lug on rear end of converter primary pump hub *(CAUTION - Do not clamp indicator on bearing surface)* so that indicator bears against rear face of housing at 3¾" radius. Rotate flywheel while holding end thrust in one direction. Runout should not exceed .005". If runout of bell housing face exceeds .005", cement paper shims of proper thickness to rear face of crankcase to bring runout to .005" or less, with all bolts fully tightened.

Pilot Hole Runout: Mount dial indicator and Hole Attachment KMO-30-F to bear against inner edge of pilot

CONTINUED ON NEXT PAGE

DYNAFLOW DRIVE (C nt.)

hole in housing. Runout of pilot hole should not exceed .004". If runout greater, remove bell housing and remove the two dowels. Reinstall bell housing, leaving bolts just loose enough to permit shifting housing by tapping with a lead hammer. Set up dial indicator as indicated above and bring pilot hole of bell housing within .004" runout by tapping in required direction with a lead hammer. If it is not possible to move housing enough, remove housing and drill bolt holes with a ½" drill. When bell housing is placed so that runout is .004" or less, tighten all bolts securely. Ream the two dowel holes through housing and crankcase using Reamer J-2548-3 (17/32") until this reamer bottoms in hole, then finish with bottoming Reamer J-4710-6 to provide full size to bottom of hole. Remove bell housing and install oversize dowels in crankcase.

ENGINE BALANCING

►*IF VIBRATION NOTED AFTER INSTALLATION OF CRANKSHAFT, FLYWHEEL, OR OTHER ROTATING PARTS, CORRECT THIS UNBALANCED CONDITION AS FOLLOWS:*

►*CAUTION:* Procedure below will correct minor unbalance caused by replacement of individually balanced parts. Extreme vibration caused by parts abnormally out of balance, or different in weight from corresponding parts, should be corrected by replacement of these parts.

Critical Speed of Vibration - Determine speed at which vibration is most evident (use tachometer) and operate engine at this speed to check results from the following corrective procedures.

1) Remove bell housing cover and install one balance weight (.060" thick) under head of two converter pump cover bolts, and tighten bolts to 25-30 ft. lbs. *(CAUTION - Do not place a weight at a flywheel-to-converter driving bolt as these bolts are not long enough for addition of weights).*

2) Run engine at critical speed and carefully compare vibration with that obtained without the weight, then stop engine. Mark location of balance weight on converter pump, remove weight and tighten bolt to 25-30 ft. lbs. Install the weight at other converter pump cover bolts and compare vibration produced at critical speed.

3) At the point where balance weight produced greatest improvement in vibration, install weights of proper thickness to eliminate objectionable vibration. Balance weights are furnished in the following thicknesses:

Balance Weight Part Nos.

1954 Models

Thickness	Part No.
.0345"	1341420
.060"	1341419
.120"	1341418

1955-56 Models

Thickness	Part No.
.0345"	1166600
.060"	1166601
.120"	1166602

1957-60 Models

Thickness	Part No.
.009"	1178106
.018"	1178107

.060"	1178109
.120"	1178110

BUICK FLIGHT PITCH DYNAFLOW

Buick (1958-59)

►CHANGES, CAUTIONS, CORRECTIONS

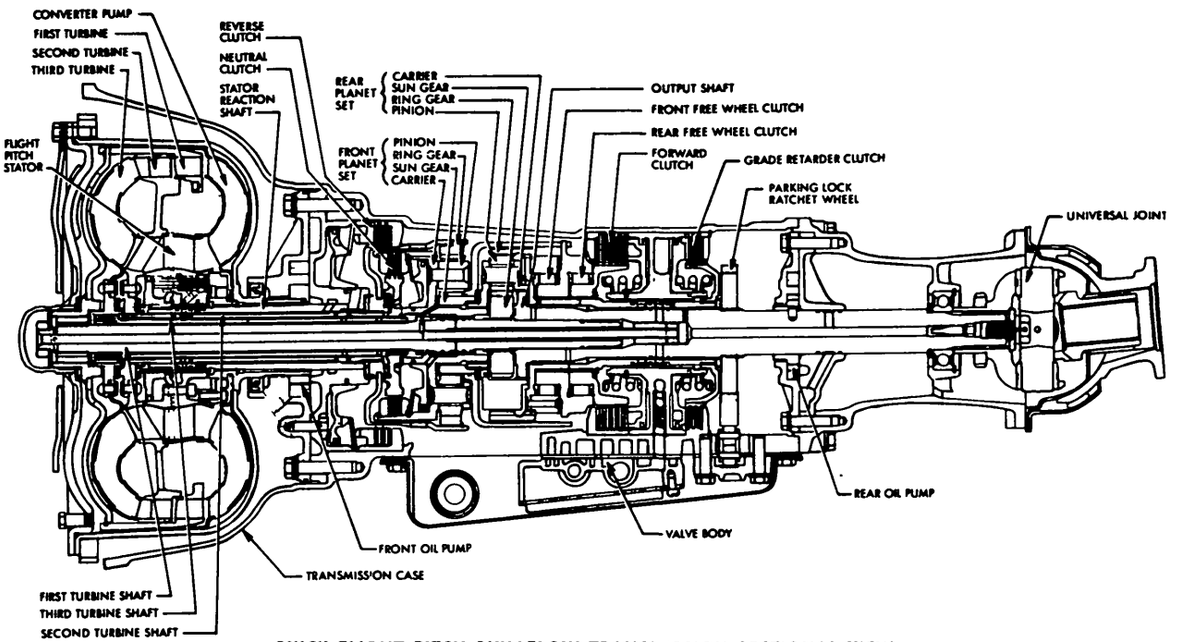
►*STARTING ENGINE BY PUSHING CAR (1958 MODELS): NOTE - 1959 models cannot be started by pushing due to limination of rear il pump.* Place control lever in "N" (Neutral) until car reaches approximately 30 MPH, then shift control lever into "G" (Grade Retard) position. Increase car speed until engine starts. After engine starts, return control lever to "N" (Neutral). *CAUTION - It is not saf to tow car to start it.*

►*TOWING FLIGHT PITCH DYNAFLOW DRIVE CARS:* With transmission selector lever in "N" (Neutral) position, the car may be towed at a speed not to exceed 35 MPH. *CAUTION - Do n t tow a Flight Pitch Dynaflow Driv car in any oth r rang .*

►*1958 REVERSE BOOSTER VALVE CHANGE (To provid a mor cushi ning ffect on reverse clutch application): Se "Overhaul" b l w.*

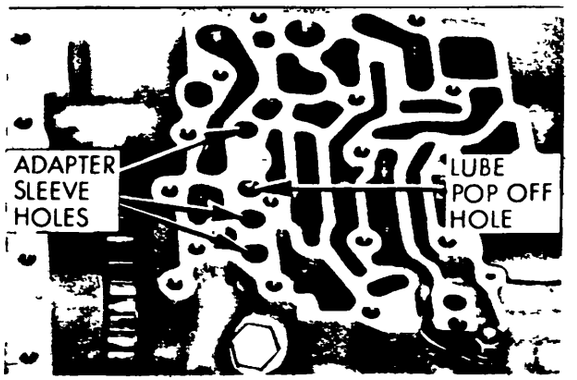
►*FILLER PIPE INTERFERENCE (Causing Vibration):* May be caused by a "Variable Pitch" Dynaflow filler pipe being installed. Check and replace with correct filler pipe if necessary.

►*1958 FLIGHT PITCH TRANSMISSION MOUNTS CHANGE:* New softer mounts, Part Nos. 1187700(right), 1187701 (left) are being used in production and for service replacement. The later type mounts are identified by the above numbers molded into the rubber, or by a daub of yellow paint. Earlier type mounts are identified by Part Nos. 1180351 (right), 1180351 molded into the rubber. *CAUTION - Do not use one early type and one lat r type m unt on the same car.*



►*1958 TRANSMISSION OIL COOLER HOSE CLAMP CHANGE (T liminat l akage):* At each connection between hose and line, two clamps will be used (one "Wittek", with copper-plated screw for identification, and one "Corbin", dyed green). Part numbers are as follows: "Wittek" (274307); "Corbin" (272846).

►*1959 TRIPLE TURBINE TRANSMISSION SUPPORT REMOVAL & INSTALLATION. CAUTION:* Before any service operation requiring the removal of transmission support is performed, the original location of the support must be marked so it can be reinstalled in exactly the same location and at the same angle. Improperly installed support will cause drive line stress and roughness.



►*1959 TRANSMISSION OUTPUT SHAFT-TO-REAR SUN GEAR NEEDLE BEARING REPLACEMENT CAUTION (TO PREVENT FAILURE OF BEARING):* When replacing the needle bearing, it must be installed with the cage inside diameter radius toward the fillet radius of the output shaft. The split line of cage halves must be away from shaft flange.

►*1959 TRANSMISSION REVERSE CLUTCH SEAL FAILURE CORRECTION:* If the reverse piston seal fails, it may be due to a roughly machined surface on sealing surface of the reaction flange. To prevent repeated failure, smooth the sealing surface on reaction flange by polishing with fine crocus cloth.

►*1959 TRANSMISSION "BUZZING" NOISE AT IDLE CORRECTION:* This condition may be caused by the lubrication pressure regulator ball vibrating on its seat and can be corrected by positioning the lubrication regulator spring retainer approximately .060" further into the output shaft support as follows: Drain oil from pan and remove pan and valve body. Insert a 5/16" steel or copper tube in lubricating circuit "pop-off" hole (see illustration for location) until it contacts lube pressure regulator spring retainer, then scribe a line on tubing flush with case. Cut tubing 1/16" longer than scribed mark and drive tube into "pop-off" hole until it is flush with case. Leave tubing in position and reassemble valve body to case using a new gasket. Check adjustment of stator valve and manual shift valve *(see "Buick Flight Pitch Dynaflow Drive" in 1958 Annual Data or later Manual edition).* Install oil pan using a new gasket and install filler tube and fill transmission with fluid. Adjust stator linkage *(see "Linkage Adjustments" below).*

BUICK FLIGHT PITCH DYNAFLOW TRANSMISSION SECTIONAL VIEW

BUZZING NOISE CORRECTION

DESCRIPTION: *NOTE - Except for elimination of rear oil pump on 1959 models, 1958 & 1959 transmissions are the same.* This transmission is an automatic non-shifting, hydraulically controlled planetary transmission with a five unit torque converter having three turbines and a variable pitch stator assembly. These units are connected through two planetary units to the output shaft. The variable pitch stator, located between third turbine exit and converter pump entrance, is infinitely variable and is controlled through a hydraulic piston by the accelerator pedal. In addition to the two planetary units, four disc type clutches are provided for Neutral, Forward, Reverse, and Grade Retarder operation. Engagement and disengagement of these clutches is accomplished only by movement of transmission range selector lever. A parking lock pawl engages a gear which is integral with output shaft when range selector lever is placed in "P" (Park) position. Transmission clutches and torque converter variable pitch stator are hydraulically controlled by pressure supplied from front and rear oil pump (1958 Models); front oil pump (1959 Models). A valve body mounted on bottom of transmission and submerged in oil contains units to regulate oil pressure, control operation of clutches and provide manual selection of the operating ranges. When transmission is in "D" (Drive) range, torque multiplication is provided by "first turbine" for starting and low speed operation. The "second turbine" is used for intermediate speeds and acceleration purposes and comes into operation after the "first turbine". The "third turbine" is used for cruising and

CONTINUED ON NEXT PAGE

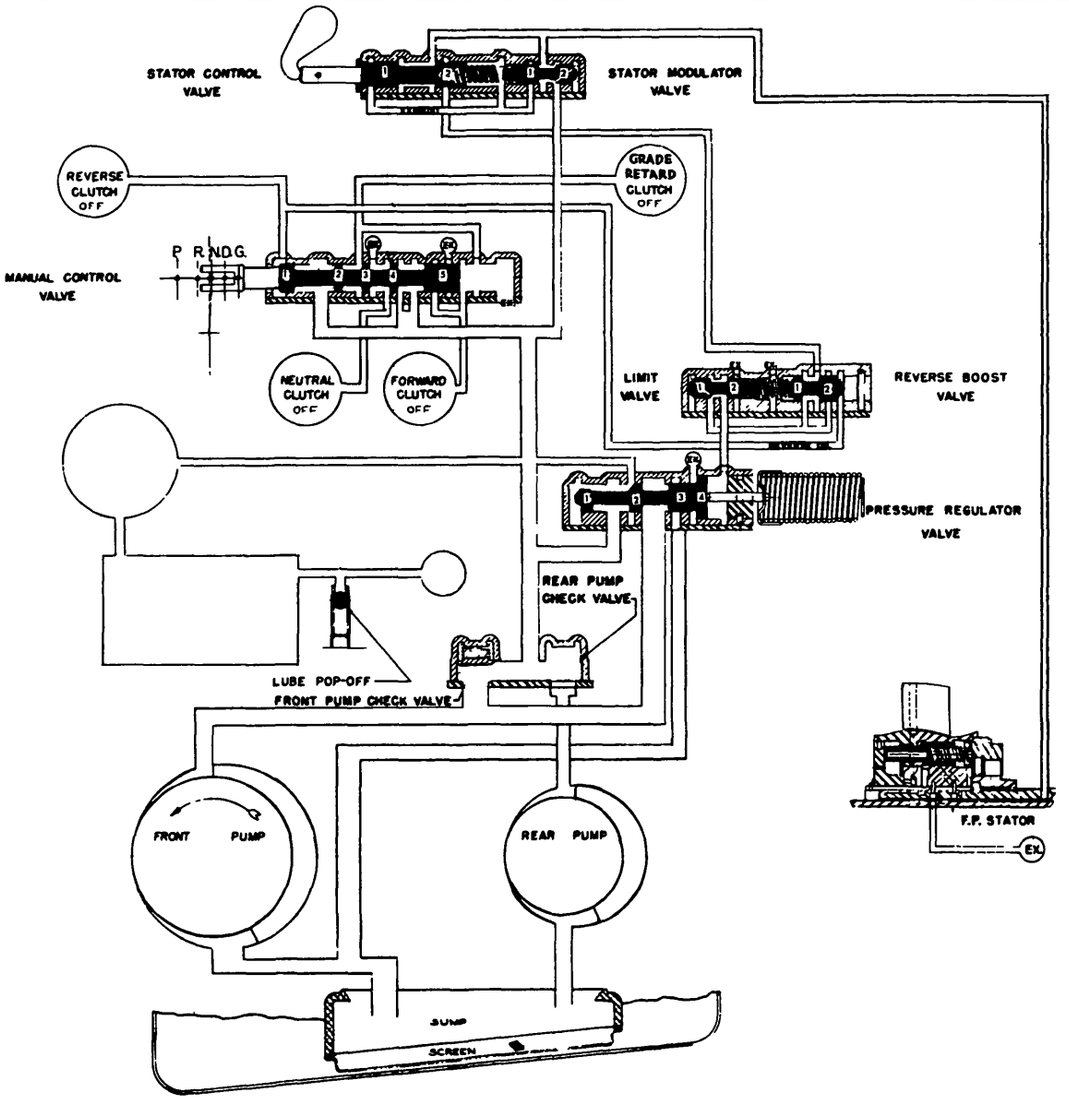
FLIGHT PITCH DYNAFLOW (C nt.)

high speed operation and comes into operation after the "second turbine". The actual point where each turbine provides torque to output shaft is dependent on car speed, engine speed, and throttle position.

OPERATION

NEUTRAL (Selector Lever in "N"): All four clutches are released and no drive is transmitted to transmission output shaft. Engine can be started in "N".

PARK (Selector Lever in "P"): All clutches are released (as in Neutral). The parking lock pawl is engaged with a gear on output shaft which prevents output shaft from rotating. Engine can be started with transmission in "P".



DRIVE (Selector Lever in "D"): Reverse clutch and grade retarder disc clutches are released. Neutral clutch and forward clutch are applied. Power transmission is through planetary units and putput shaft as indicated below. As each of the three turbines are directly connected to a component of the two planetary units, power transmission varies in relation to turbine or turbines in operation depending on engine speed and throttle position.

P wer Range: As accelerator is pressed to set car in motion, the engine drive pump starts, increasing with engine speed, and delivers nearly all of its output to first turbine. Motion of first turbine is transmitted to sun gear of rear planetary gear set, causing transmission shaft to be driven at reduced rate as the rear planetary gears are forced to "walk" around their ring gear. The ring gear cannot rotate backwards because of its one way clutch. In this phase of operation, greatest transmission torque multiplication is obtained. Transmission gear reduction is 2.86-1.

Acc leration Range: As car speed increases, angle of oil pumped by converter pump changes due to engine RPM and, because of the angle of first turbine blades, the oil starts to drive second and third turbine in a progressive and overlapping action while output of first turbine diminishes. Output of second turbine is transmitted to output shaft through the front planetary sun gear at a 1.54-1 reduction. Reduction in the front gear set is obtained by turning the ring gear which causes planet gears to "walk" around sun gear and transmit their speed to the output shaft. The sun gear is prevented from turning backwards by a one way clutch. When second turbine reaches maximum torque, the first turbine is released and freewheels in converter pump oil stream. Like the first turbine declining action, as engine speed continues to increase, less oil pressure plays on the second turbine vanes but more reacts on the third turbine. Because of its direct connection to output shaft, the third turbine is more favorable for high speed acceleration.

Cruising Range: When fluid coupling point of the torque converter is reached, the transmission is in cruising range. At this stage, work of the second turbine is completed and it is released by a clutch to freewheel in converter housing with the first turbine. All output is now from third turbine which is connected mechanically to output shaft at a 1 to 1 ratio.

Variable Pitch Stator: The above operations have occurred without reaching the half throttle position and the flight pitch stator blades have remained in the low angle "cruise" position. If accelerator pedal is depressed to the half throttle position or beyond, the stator blades will be shifted to a higher angle through the hydraulic control action. As the angle of stator blades is increased, the stall speed and torque multiplication of the converter are increased providing higher performance for rapid acceleration. Position of stator blades is infinitely variable between low angle and high angle and is entirely governed by throttle position (beyond the half throttle position). High stator blade angle is reached simultaneously with wide open throttle.

FLIGHT PITCH DYNAFLOW HYDRAULIC CIRCUITS

GRADE RETARDER: Grade Retarder clutch is applied and all other transmission clutches are released. Grade Retarder "G" range should not be entered at car speeds above 45 MPH. When grade retarder position is applied, the multiple disc clutch on rear planetary gear set ring gear is engaged and all other clutches are released. This drives the first turbine at 2.86-1 times output shaft speed, while the second and third turbines freewheel. The pumping action of the first turbine creates a turbulence in the converter which effectively brakes the car by increasing engine speed and by transferring energy into heat in the converter oil. The heat is then dissipated by engine cooling system.

CONTINUED ON NEXT PAGE

FLIGHT PITCH DYNAFLOW (C nt.)

REVERSE: The reverse multiple disc clutch holds ring gear of planetary gear set and second turbine stationary. The neutral clutch is also applied. As engine is accelerated, the first turbine moves, turning its shaft and rear planet set sun gear. This causes rear planet set pinions to revolve the ring gear opposite to pump rotation. The rear planet set ring gear freewheel clutch thus engaged rotates the front planet set sun gear freewheel clutch, and forward clutch hub opposite to pump rotation. This causes front planet pinions to turn and "walk" around the stationary ring gear, turning the planet carrier and output shaft opposite to pump rotation, and accomplishing the reverse operation.

LUBRICATION

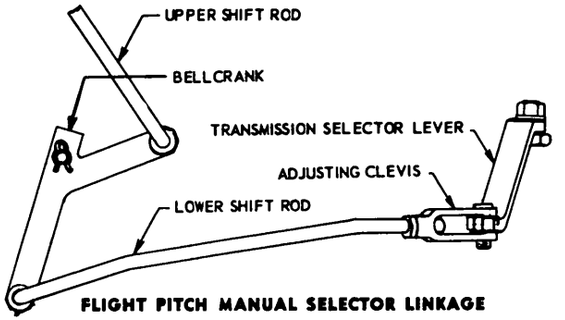
Check oil level at 1000 mile intervals, drain and refill every 25,000 miles.

Capacity - 12.5 quarts. *NOTE - A completely dry transmissi n (aft r v rhaul) will require an additional 1 1/3 pints.*

Rec mmend d Oil - Special Buick Oil for Dynaflow Drive or Automatic Transmission Fluid Type "A" bearing an AQ-ATF number embossed on the can.

Checking Fluid Lev l: With transmission at normal operating temperature, transmission selector lever in "N", oil level should be at "Full" mark on dipstick. Add oil as necessary. *CAUTION - Do not overfill.*

Draining & R filling: With transmission at normal operating temperature, engine turned off, loosen one drain plug in converter housing and rotate converter 180°, then remove the opposite drain plug and drain converter. Remove filler pipe from side of transmission oil pan (or drain plug, if so equipped), and drain oil from transmission. To refill, install drain plugs in converter and tighten securely, then install filler pipe, or drain plug, to transmission oil pan. Add four quarts of Automatic Transmission Fluid Type "A" to transmission. Raise rear wheels and with transmission in "D" (Drive) range and engine idling, add 8½ quarts more. Place transmission selector lever in "N" and lower rear wheels to ground. Check oil level and add oil as necessary to bring level to "Full" mark on dipstick.



LINKAGE ADJUSTMENT

Thr ttl Linkage: *S "Carburetor" on Car Model pages.*

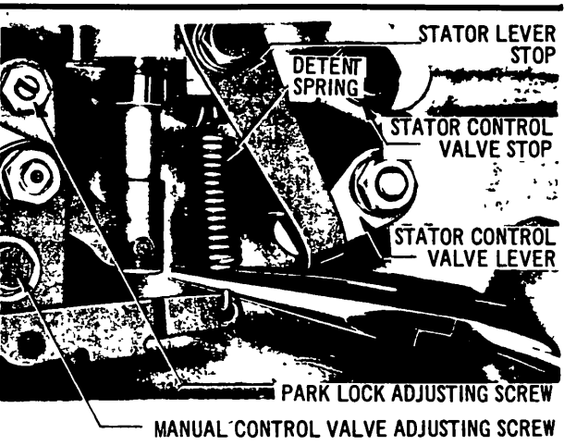
Manual Linkag : *CHECKING NOTE* - To check linkage adjustment, move manual control lever carefully until transmission is shifted into its "D" (Drive) range position (manual lever will seem to seat). Move manual lever toward "G" (Grade Retard) without lifting lever toward steering wheel, and note distance it travels before contacting the stop. Return lever to "N" (Neutral) position, then move the lever to "R" (Reverse) position and note how far it moves before it contacts stop. If movement from drive detent to stop is the same as movement from "N" (Neutral) detent to stop, manual linkage is correctly adjusted.

Adjustm nt - Loosen locknut on clevis at shift lever on transmission, then remove cotter pin, clevis pin, and spring washer. Lengthen or shorten lower shift rod by turning clevis until distance from "D" (Drive) detent to stop is the same as from "N" (Neutral) detent to stop. Check pointer on transmission selector dial; if dial is not properly adjusted, pry off dial, loosen nut and adjust pointer in Drive range. *(NOTE* - If external linkage has been checked and adjusted and transmission still does not shift properly, the transmission oil pan must be removed and internal linkage checked and adjusted).

Stator Linkage: With throttle in hot idle position, adjust upper stator rod so that ball joint at forward end will just slip freely into stator lever with both stator lever and stator rod pushed rearward. Shorten stator rod **one full turn** to provide clearance at stop inside transmission case. Reconnect ball joint to stator rod and tighten nut.

FLIGHT PITCH MANUAL SELECTOR LINKAGE

►*STATOR LINKAGE ADJUSTMENT NOTE:* If upper stator rod length cannot be adjusted to slip freely in stator lever with rod and lever pushed rearward, check to make sure that correct stator rod is installed on car.



Neutral Safety Switch Adjustment: With transmission manual control linkage in proper adjustment, place shift control lever in "N" (Neutral) position. Insert a 3/32" drill through gauging hole in operating lever and through gauging hole in switch body. *CAUTION* - Do not move shift control lever out of Neutral position. If gauging drill is now parallel with centerline of steering column jacket, neutral switch timing is correct. If gauging drill will not go through holes or is not parallel with jacket, loosen two switch mounting screws and move switch sideways until gauge is parallel, then retighten screws. To check adjustment, turn on ignition switch, place shift control lever in reverse, and make sure back-up lights are operating. Set parking brake, place selector lever in "N" (Neutral) and make sure engine will start. Place shift lever in "P" (Park) and and check to see if engine will start.

CONTROL VALVE & PARKING LOCK ADJUSTMENT

►*ADJUSTMENT NOTE: Oil pan must be removed to make the following adjustments. See "Overhaul" below.*

Stator Valve Adjustment: Swing lever stop aside and slip a .040" feeler gauge into position between valve body and valve stop. Press stator valve stop toward valve body and hold in this position by tightening valve body bolt.

Stat r C ntr l L v r St p Adjustm nt: Position lever stop over stator control lever, then place a .005" feeler gauge between end of stator valve and lever. Hold lever "out" and lever stop against lever. Tighten lever stop clamp bolt in this position, then install detent spring.

CONTROL VALVE & PARK LOCK ADJUSTMENT LOCATIONS

Manual Shift Valve Adjustment: With transmission in "Park" position (detent plate rotated rearward to last notch), loosen manual control valve adjusting bolt and insert a 9/64" drill between inner edge of first land of manual valve and valve body. Hold valve "in" toward valve body, with drill in position, and at same time hold detent lever solidly in notch, tighten adjusting nut.

Parking Lock Adjustment: With transmission in "Park" position, loosen parking lock adjusting screw and insert a .015" feeler gauge between parking lock roller and slide cover. Turn eccentric screw to give .015" clearance between roller and slide cover. Hold screw in this position and tighten nut.

TROUBLE SHOOTING

TRANSMISSION OIL FOAMS AND RUNS OUT OF BREATHER OR FILLER PIPE: Transmission overfilled. Check the following:

1) Check for blackened condition of oil, indicating leakage of rear axle lubricant into transmission due to a defective propeller shaft seal. Correct cause of leakage and completely drain and refill transmission. Check for low oil level in rear axle housing.

2) If transmission oil is caramel colored, water in transmission is indicated and is caused by leakage in the oil cooler. Oil in top of radiator tank will also be noted. Correct cause of water leakage and completely drain and refill transmission.

CAR WILL NOT MOVE IN ANY RANGE (REAR WHEELS FREE):

1) Linkage incorrectly adjusted.

2) Low or no front pump pressure due to one or more of the following: Low oil level. Oil screen clogged. Worn or scored front pump and/or reaction flange. Case and/or valve body gaskets not sealing and allowing air to enter hydraulic circuits. Pressure regulator valve binding and hung up.

CAR WILL NOT MOVE FOR SEVERAL SECONDS AFTER STANDING OVERNIGHT (BEGINS TO MOVE SUDDENLY):

1) Front pump loses prime. Check pump clearances and examine pump body and gears for scoring. *S "Oil*

CONTINUED ON NEXT PAGE

FLIGHT PITCH DYNAFLOW (C nt.)

Pump Ov rhaul" below. If pump not within limits, replace pump.

CAR WILL MOVE ONLY SLOWLY FOR SEVERAL SECONDS AFTER STANDING OVER NIGHT (GRADUALLY BEGINS TO OPERATE NORMALLY):

1) Converter leakage or leak down. Check clearance between first turbine shaft-to-hub. This clearance should be .002-.009". Surface of first turbine hub where anti-leak down valve seats should be smooth to allow valve to seat properly. To check sealing of anti-leak down valve, assemble valve and spring into hub and set hub on bench to hold valve in position. Pour kerosene in any one of the four holes until level is visible, then note if level falls. Kerosene should be retained several minutes.

2) Check stator valve spring retainer which should fit tightly in bore of stator rear carrier. If a retainer can be forced down into bore with thumb pressure, it is too loose and should be replaced.

CAR WILL NOT MOVE IN ANY FORWARD RANGE:

1) Forward and neutral clutches not operating.
2) Rear sprag and neutral clutches not operating.
3) Reverse clutch stuck in applied position.

CAR WILL NOT MOVE IN REVERSE RANGE:

1) Reverse clutch not operating.
2) Forward clutch stuck in applied position.
3) Grade retard clutch stuck in applied position.
4) Front sprag not operating.

NO GRADE RETARD OPERATION:

1) Grade retard clutch not operating.
2) Will not shift into GR detent because of binding in parking pawl slide and roller.

EXCESS SLIPPAGE IN FORWARD AND REVERSE:

1) Low oil level or linkage not adjusted properly.
2) Forward and neutral clutches slipping, or low front pump pressure.
3) Front sprag not operating properly. Rear sprag not operating properly.
4) Stator control valve linkage not properly adjusted.
5) Converter drain check valve not operating properly (or missing), or pressure regulator valve stuck in bypass position.

EXCESS SLIPPAGE AT HIGH THROTTLE AND NO TOP SPEED IN FORWARD RANGE:

1) Neutral clutch not applying or neutral clutches slipping.
2) Stator control valve linkage not adjusted properly.

CAR CREEPS FORWARD IN NEUTRAL:

1) Linkage not properly adjusted.
2) Neutral clutch and/or forward clutch not releasing or not assembled properly.
3) Grade retard clutch not releasing or not assembled properly.

CAR WILL NOT HOLD IN PARK OR WILL NOT GO INTO PARK:

1) Linkage not properly adjusted.
2) Parking pawl slide and roller binding, or parking pawl broken.
3) Grade retard backing plate retainer ring not in groove or missing.

FORWARD CLUTCH DOES NOT OPERATE PROPERLY:

1) Low apply pressure due to: Valve body and/or case gaskets not sealing. "0" rings on adaptor sleeve damaged or missing. Piston outer seal and/or inner oil ring damaged or missing. Porous output shaft support. Modulator valve and/or limit valve hanging up due to burrs or dirt. Neutral clutch apply circuit has excessive leak.
2) Piston and/or output shaft support damaged or burred causing piston not to apply or release.
3) Piston outer seal lip turned over causing piston to hang.
4) Clutch plates warped, worn, or not properly installed.

NEUTRAL CLUTCH DOES NOT OPERATE PROPERLY:

1) Low or no apply pressure due to: Valve body and/or case gaskets not sealing. "0" rings on adaptor sleeve damaged or missing. The two rear oil rings on grade retard reaction shaft damaged or missing. The two front oil rings on output shaft damaged or missing. Any one of, or all, of first turbine shaft oil rings damaged or missing. Piston outer seal and/or inner oil ring damaged or missing. Forward clutch apply circuit has excessive leak.
2) Piston and/or front carrier damaged or burred causing piston not to apply or release.
3) Piston outer seal lip turned over causing piston to hang.
4) Clutch plates warped, worn, or clutch backing plate retaining ring not properly installed or missing.

REVERSE CLUTCH DOES NOT OPERATE PROPERLY:

1) Low or no oil supply due to: Valve body and/or case gaskets not sealing. Porous apply channel in case. Reaction flange gasket not sealing. Reaction flange and/or case mating surfaces irregular. Piston outer seal and/or inner oil ring damaged or missing. Reverse boost valve hanging up because of burrs or dirt.
2) Piston and/or reaction flange damaged causing piston to hang.
3) Piston outer seal lip turned over causing piston to hang.
4) Clutch plates warped, worn, or not properly installed.
5) Clutch pressure plate not properly installed.

GRADE RETARD CLUTCH DOES NOT OPERATE PROPERLY:

1) Low or no apply pressure due to: Valve body and/or case gaskets not sealing. Adapter sleeve "O" rings damaged or missing. Piston outer seal and/or inner oil ring damaged or missing. Porous output shaft support.
2) Piston and/or output shaft support damaged causing piston to hang up.
3) Piston outer seal lip turned over causing piston to hang.
4) Clutch backing plate retaining ring not properly installed or missing.
5) Clutch plates warped, worn, or not properly installed.

STATOR DOES NOT OPERATE PROPERLY:

1) Low or no apply pressure due to: Valve body and/or case gaskets not sealing. Porous apply channel in case. Reaction flange gasket not sealing, or flange and mating surfaces irregular. Second turbine shaft rear oil ring damaged or missing. The two front oil rings on second turbine shaft damaged or missing. Any one of three oil rings on reaction shaft damaged or missing. One or both of the front oil rings on second turbine shaft damaged or missing. Stator modulator valve or limit valve hanging up.
2) Stator piston ring damaged or missing or incorrect ring and gap.
3) Stator blades not rotating freely due to: Piston bound up in bore or carriers because of burrs or dirt. Stator blade ring damaged or stator blades damaged. Front and/or rear carrier damaged or dirty.
4) Stator piston retaining ring improperly installed or missing.
5) Stator piston control valve not gauged properly or shims below spring not lying flat in bore.
6) Stator piston control valve hanging up in either position due to roughness of rear carrier bore, burrs, or dirt.
7) Stator piston control valve retainer not in proper position or missing.
8) Stator free wheel rollers not properly installed or roller spring damaged or missing.
9) Linkage improperly adjusted or incorrect upper stator control operating rod.

TESTING

►*TESTING CAUTION: Before testing transmissi n, ch ck oil level and bring it to the full mark n dipstick (s LUBRICATION above).*

PRESSURE TEST: With engine and transmission at normal operating temperature, support car in a safe manner with wheels off the floor, and brakes off. Connect pressure gauge at point to be checked (see pressure test point illustration). Disconnect stator lever linkage to allow stator lever position to be changed without moving throttle. Connect a tachometer to engine, then with

Reverse	1000	High Angle	80-90	② 170-180	0	0	② 170-180	5-45

① - Hot

② -190-210 lbs. on first cars without T-061 Reverse Boost Valve Spacer.

FLIGHT PITCH DYNAFLOW (C nt.)

engine running at the correct speed, take pressure reading (s "Pressur T st Sp cifications"

►*CAUTION: D n t driv car on road with stator linkage disc nn cted.*

STATOR OPERATION TEST: With engine and transmission at normal operating temperature, make sure stator linkage is properly adjusted, then connect a tachometer and start engine. Place transmission in "P" (Park) range and set engine idle speed at exactly 1500 RPM (high step of fast idle cam). Adjust fast idle if necessary. Block wheels, then have a helper firmly apply brakes and shift transmission to "D" (Drive) range. Engine speed should decrease to 1000 RPM ± 60 RPM. If engine speed does not decrease sufficiently, the stator blades are in high angle position or not fully in low angle position. If engine speed decreases to 1000 RPM, stator blades are in low angle position. Move stator control lever on carburetor forward to high angle position without disturbing throttle setting. In a few seconds, engine speed should increase approximately 150 RPM. If engine does not increase approximately 150 RPM, it is an indication that stator blades are not shifting fully to high angle position. If engine speed increases 150 RPM or more, stator blades are making a full shift from low to high angle.

REMOVAL.

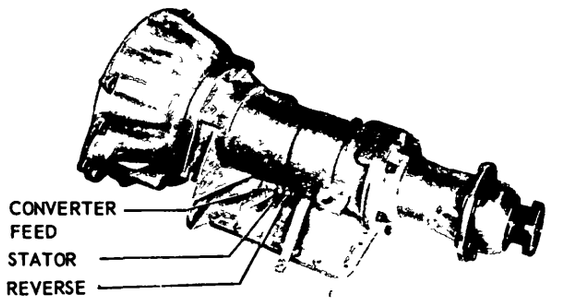
Transmission and torque converter are removed as an assembly as follows:

1) On coil spring cars, raise car at front and rear and place jack stands under frame side rails so frame is approximately 20" off floor. Disconnect torque tube from torque ball and move rear axle back to disengage propeller shaft from universal joint.

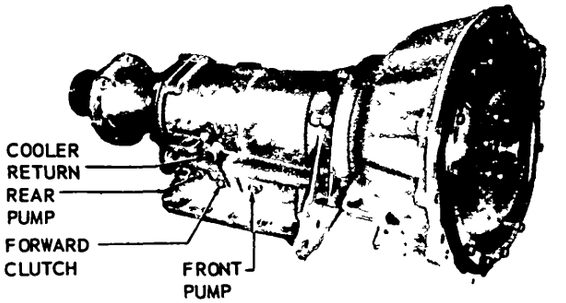
2) On cars with Air Suspension, raise car by operating manual over-ride valve on instrument panel. Raise car at front and rear, solidly supporting front suspension and rear of frame. Support rear axle housing with a floor jack. Carefully and slowly loosen air lines from rear air springs to allow air in springs to discharge, then remove plungers from air springs. Disconnect rear height control valve links at torque tube radius rods, then disconnect stabilizer bar at axle end. Disconnect lower ends of rear shock absorbers. Disconnect parking brake cable at rear axle sheave and at bracket on torque tube. Disconnect brake hose from pipe at frame X member and remove yoke (cover hose and pipe ends). Install 3" guide pins in alternate bolt holes in torque ball, then remove remaining two torque tube flange bolts. Lower axle assembly and push back to clear torque ball.

3) On all cars, disconnect exhaust pipes at manifold and loosen pipe to muffler joint, then remove converter housing cover.

4) Turn flywheel until one converter drain plug can be loosened to provide an air vent, then turn flywheel until opposite drain plug is down. Remove this plug and drain oil from converter. Remove filler pipe from transmission and allow oil to drain from transmission.



5) Remove converter to flywheel bolts, disconnect oil cooler pipes, and disconnect speedometer cable. Disconnect stator control rod at transmission lever, then disconnect lower shift rod at transmission lever and upper shift rod at idler lever. Leave lower rod, idler lever and bracket attached to crossmember.



6) Support transmission securely and use jack to safely support engine. Remove two nuts and four bolts and nuts holding mounts to support then raise engine and transmission just enough to relieve strain on support. Remove eight attaching bolts and nuts and remove transmission support. *NOTE - If shims are found at support, note number and location so they may be installed in original position.* Lower transmission sufficiently to remove six transmission case to crankcase bolts.

7) With engine separately supported, move transmission to rear to disengage converter pump cover from crankshaft. Lower transmission and remove from car. *CAUTION - Do not tilt transmission forward as weight of converter may damage bushings in front planet carrier, and oil rings n first turbine shaft.*

1958 OIL PRESSURE TEST POINTS

1959 OIL PRESSURE TEST POINTS

OVERHAUL

►*1958-59 TRANSMISSION OVERHAUL NOTE: Overhaul pr c dures f r 1958 and 1959 are the same exc pt for references made to rear oil pump. A rear oil pump is not used on 1959 models.*

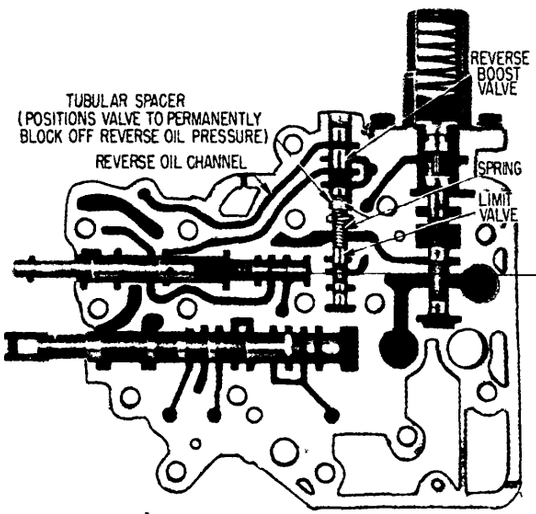
►*CONVERTER CLEARANCE GAUGE (TOOL J-5899) REWORK FOR USE WITH FLIGHT PITCH TRANSMISSION TORQUE CONVERTER:* This gauge, designed for "Variable Pitch" and earlier Dynaflow transmissions can be reworked for use on "Flight Pitch" transmissions as follows: *CAUTION - Because of finish grinding and close tolerances of gauge plunger, it is very important that both the gauge body and plunger be marked to insure that it will be replaced in body in same position.* Remove plunger from gauge body and decrease outside diameter of one end of plunger to 2 3/8" ± 1/64" for a distance of 3/8".

►*TRANSMISSION HOLDING TOOL (J-7009) CAUTION:* To prevent case distortion and damage, tighten only two transmission attaching bolts on one side, leaving the other two bolts finger tight.

►*1958 REVERSE BOOSTER VALVE CHANGE (To provide a more cushioning effect on reverse clutch application):* A new Reverse Boost Valve Spacer, Part No. 1186397, is being used in production beginning with Transmission Code No. T061, and is recommended for installation on earlier transmissions. The purpose of this spacer is to provide a cushioning effect on reverse clutch application. See illustration for location of spacer. After installation of spacer, indicate the change by stamping an "X" near code number

►*1958 FIRST TURBINE HUB & SHAFT PRODUCTION CHANGE & SPECIAL TOOL NOTE:* Two changes have been made in production as follows· The first

CONTINUED ON NEXT PAGE



FLIGHT PITCH DYNAFLOW (C nt.)

change resulted in a reduction of clearance between turbine hub splines and splines of turbine shaft. The above reduction should provide a slip fit, however, an assembly may be found requiring force to disassemble and reassemble. The second change resulted in a definite press fit between turbine hub splines and splines of turbine shaft. Turbine shaft splines have been increased in size for the last 3/16" on shaft which means that turbine shaft should slip on hub until it reaches oversize spline and then it will have to be pressed into place. To disassemble, it will be necessary to pull disc and hub assembly from shaft using Tool J-7392. Assembly of these parts will require use of Tool J-7392-1 and J-7392-2.

►*1958 STATOR NEEDLE THRUST BEARING (STATOR CAM-TO-CONVERTER PUMP HUB) PRODUCTION CHANGE & REPLACEMENT PARTS CAUTION:* Approximately 500 cars at start of production were built with needle thrust bearings (stator cam to converter hub) having smaller diameter needles than on later production. Early production needle thrust bearings were matched with a bearing race .100" thick. Later thrust bearings, Part No. 1182993, are used with a thinner race. Part No. 1182992 which is .061" thick. Only later type bearings are available for service replacement and must be installed in sets.

►*1958 NEUTRAL CLUTCH FAILURE CORRECTION:* In cases of failure of neutral clutch, examine neutral clutch, backing plate retaining groove to determine if the groove is square. If groove is not square, retaining snap ring will be allowed to work out when pressure is applied, resulting in clutch slippage. If this condition exists, it will be necessary to replace Front Planet Carrier and Reverse Clutch Spring.

►*1958 STATOR REAR CARRIER CHANGE (To prevent stator pist n contr l valve sticking in bore):* Beginning Transmission No. V020 & T129, stator piston control valve bore in rear carrier has been changed to include an undercut at front side of bore. The undercut on stator piston control valve was eliminated when above change made *CAUTION - When replacing stator piston control valve, care must be taken to install the same type as removed. First type Stator Piston Control Valve, Part No. 1181096 (with undercut); later type Stator Piston Control Valve 1186407 (without undercut).*

FLIGHT PITCH DYNAFL W REVERSE B STER VALVE CHANGE

►*1958 TRANSMISSION BUSHING REPLACEMENT NOTE: Front Pump Bushing, Front Planet Carrier Bushing, and Output Shaft Support Bushing CANNOT BE REPLACED in transmission, due to being machined after assembly. All other bushings can be replaced*

►*1959 TWIN TURBINE TRANSMISSION PRODUCTION CHANGES:* The following changes have been made since the start of 1959 production:

Neutral Clutch Inner Seal - Beginning with transmission code number Z-021, the cast iron oil seal ring which is assembled to front planet carrier, Part No. 1388305, and acts as an inner seal for neutral clutch piston, Part No. 1180144, has been changed to a rubber type seal, Part No. 1182642. This seal is not interchangeable with earlier cast iron seal except when the following parts are also used.

Front Planet Carrier - A new carrier, Part No. 1185643 is being used to accommodate the later type rubber seal and is interchangeable with the previous type when used with the new seal (see above).

Neutral Clutch Piston - A new piston, Part No. 1180144 replaces the earlier type and can be used with either the cast iron seal or rubber seal.

Grade Retard Brake Piston Inner Seal - Beginning with transmission code number Z-011, the cast iron seal ring, Part No. 1180176, which is assembled to the center hub on each side of output shaft support and acts as an inner seal for forward piston and grade retard brake piston has been changed to a rubber oil seal ring, Part No. 1182640. The new seal is not interchangeable with previous cast iron seal.

Output Shaft Support - A new support, Part No. 1185645, is being used in production to accommodate the later type rubber seal ring (see above). This new support is interchangeable on earlier cars when used with the new rubber seal ring, Part No. 1182640.

Reverse Piston Inner Oil Seal - Beginning with transmission code number Z-021, the cast iron seal ring Part No. 1180178, (which is assembled on hub on back side of converter reaction shaft and acts as an inner seal for the reverse piston) has been changed to a rubber seal ring, Part No. 1182641. The later type rubber oil seal ring is not interchangeable with the cast iron ring except when installed with the new converter reaction shaft (see below).

Converter Reaction Shaft - A new converter reaction shaft, Part No. 1182616, is being used in production to accommodate the later type rubber seal ring (see above). The later type shaft is interchangeable on previous transmissions when used with the later type rubber seal ring.

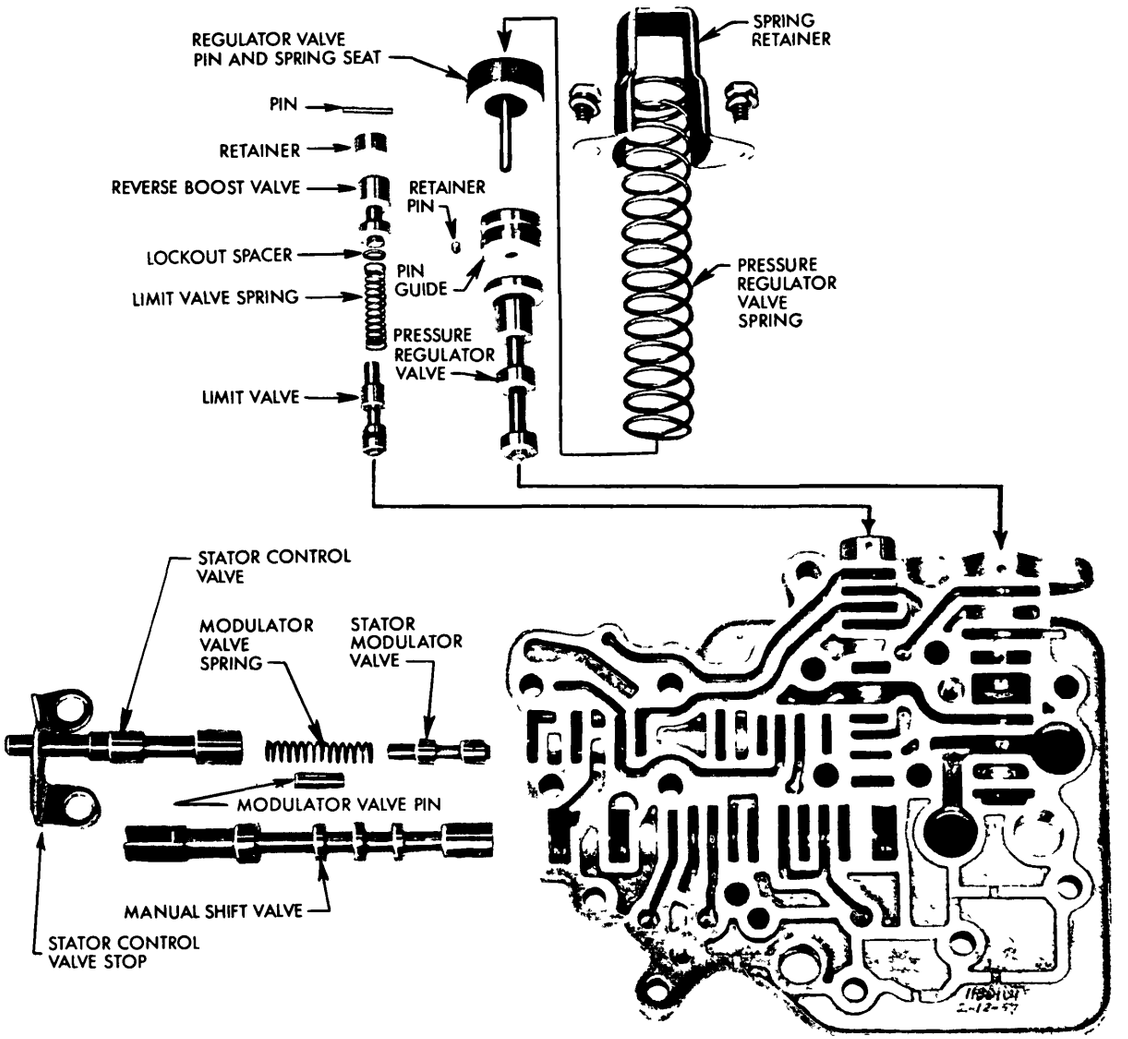
TORQUE CONVERTER REMOVAL & OVERHAUL

R moval (Fr m Transmissi n): *NOTE - S e "First Turbin Hub and Shaft Production Chang & Special Tool N te" above, then proceed as follows:* With transmission installed in Holding Fixture, Tool J-7009 *(s "Holding Tool Caution" above),* remove twelve converter cover bolts. *NOTE - Converter pump and c v r ar a balanced assembly and parts must b reass mbled in sam position. A 1/8" drilled h l in bolting flang s rves as locating mark.* Pry up converter pump cover and remove it along with "O" ring (discard "O" ring). Remove select fit bearing races and needle thrust bearing (located between bearing hub and pump cover), then loosen first turbine shaft nut. *NOTE - Us a "U" typ holder between bolt hole in convert r bolting flange and hole in bell housing to hold c nv rt r fr m turning.* Remove nut and special washer and discard washer. Use two screwdrivers or other suitable tool to lift complete first, second, and third turbine assembly from converter pump. Lift converter pump until stator race is clear of splines on reaction shaft (approximately 2½"), then lower converter pump and remove stator. Remove needle thrust bearing and bearing race (stator cam to converter pump hub), then remove converter pump. *NOTE - If captive thrust b aring rac in converter hub is worn or scored, it should b r placed (it is not necessary to replace c nv rt r pump).*

Turbine Disassembly & Insp cti n: Remove needle bearing flanged bearing race, needle bearing, and .050" plain bearing race from second turbine hub *(NOTE - These parts may have remained on top of stat r).* Before disassembling first turbine disc and hub from first turbine, mark the turbine, disc, and hubs so they may be reassembled in same position. *CAUTION - It is important these parts be prop rly mark d as they are a balanced assembly. Servic parts of thes tw items are held to close balanc tol rance, making it unnecessary to replace both parts if on r the th r r - quire replacement.* Set assembly shafts down through hole in bench, then remove first turbine-to-disc and hub retainer ring using a thin bladed screwdriver at inner edge of ring to raise edge of ring. Press on outer edge of ring to slide ring up slope of screwdriver over step of first turbine disc and hub. Remove first turbine disc, hub, and .080" lead coated thrust washer (washer is located on third turbine hub). Lift out third turbine, flanged bearing race, needle bearing, and plain .050" bearing race. Examine third turbine front bushing and if worn or scored, cut out bushing with a chisel. Install new third turbine front bushing using Tools J-7013-1 and J-7273-25. Replace rear bushing in same manner if necessary. Lift out second turbine. Inspect and if necessary to replace oil rings, unhook and expand, then remove three second turbine shaft hooked oil rings. Inspect front and rear second turbine bushings and, if necessary, remove with a chisel. Install front bushing using Tools J-7013-1 (handle), J-7273-26 and J-7273-6 (with counterbore on J-7273-6 toward handle). Install rear bushing with Tools J-7013-1 (handle) and J-7273-26. Expand and install new hooked oil rings on second turbine shaft. Hook ends of rings by holding one end firmly in groove and working other end around to

CONTINUED ON NEXT PAGE

FLIGHT PITCH DYNAFLOW (C nt.)



hook. *NOTE - S cond turbin shaft il rings ar slightly smaller (.050") than tw rings used on output shaft. DO NOT interchang th s rings.*

Turbin R ass mbly: With first turbine on bench, install second turbine (with oil rings in place) through hole in bench so it rests on first turbine. Inspect and, if necessary, install new flanged needle bearing race (flange upward), needle thrust bearing (1¾"x2½"), and plain bearing race (.050") on third turbine hub. Retain in place with heavy lubricant. *NOTE - Always measure n dl b arings and races. Some are within .010" thickn ss and 1/16" diameter of each other and can asily b ass mbl d incorrectly.* Insert third turbine shaft into second turbine shaft and lower into position. Inspect and, if necessary, place new .080" lead coated bronze thrust washer on hub of third turbine, and position first turbine disc and hub with tangs in slots of first turbine. Install first turbine disc and hub retaining ring so high edge will engage groove in first turbine and the inner lower edge forces down on first turbine disc and hub. Tap solidly into groove and check for proper installation. With assembly on bench (shafts up), inspect, and if necessary, install new flanged needle bearing race (flange up) on second turbine hub, then install needle bearing (1¾"x2½"), and .050" bearing race. *NOTE - If further work is being done on transmissi n, s t compl te turbine assembly aside. If c nv rt r is to be r assembled, refer to "Transmissi n Reass mbly" below.*

Flight Pitch Stat r Disassembly & Inspection: With stator removed from converter assembly, pull out freewheel race by rotating clockwise. Remove three special clutch head screws from stator cam-to-stator carrier using Tool 10-167-1, then pry up on freewheel and bronze washer with screwdriver using care to avoid damage to washer. Remove cam and washer. Remove five clutch head front-to-rear carrier screws using Tool 10-167-3. Invert assembly, expand and remove stator piston retaining ring from rear carrier-to-stator piston. Invert assembly and rotate all stator blades to extreme high angle position and remove stator rear carrier assembly from front carrier. Remove blades and stator blade ring from stator front carrier and piston assembly. Inspect stator rear carrier bushing. If worn or scored, remove bushing using Tool J-7013-1 (handle) and J-7273-12. To install new bushing, support carrier on a steel sleeve, then install bushing using Tools J-7013-1 (handle), J-7273-6 and J-7273-12 (counterbore on Tool J-7273-6 should be toward handle). Remove stator piston and ring from front carrier, then expand and remove ring from stator piston with snap ring pliers. If stator piston control valve is sticking or spring is weak, remove valve by supporting rear carrier, then rap sharply on valve with a plastic hammer.

►*1958 STATOR REAR CARRIER PRODUCTION CHANGE (T pr v nt stator piston control valve sticking in bore): S "Stat r R ar Carrier Production Change" above.*

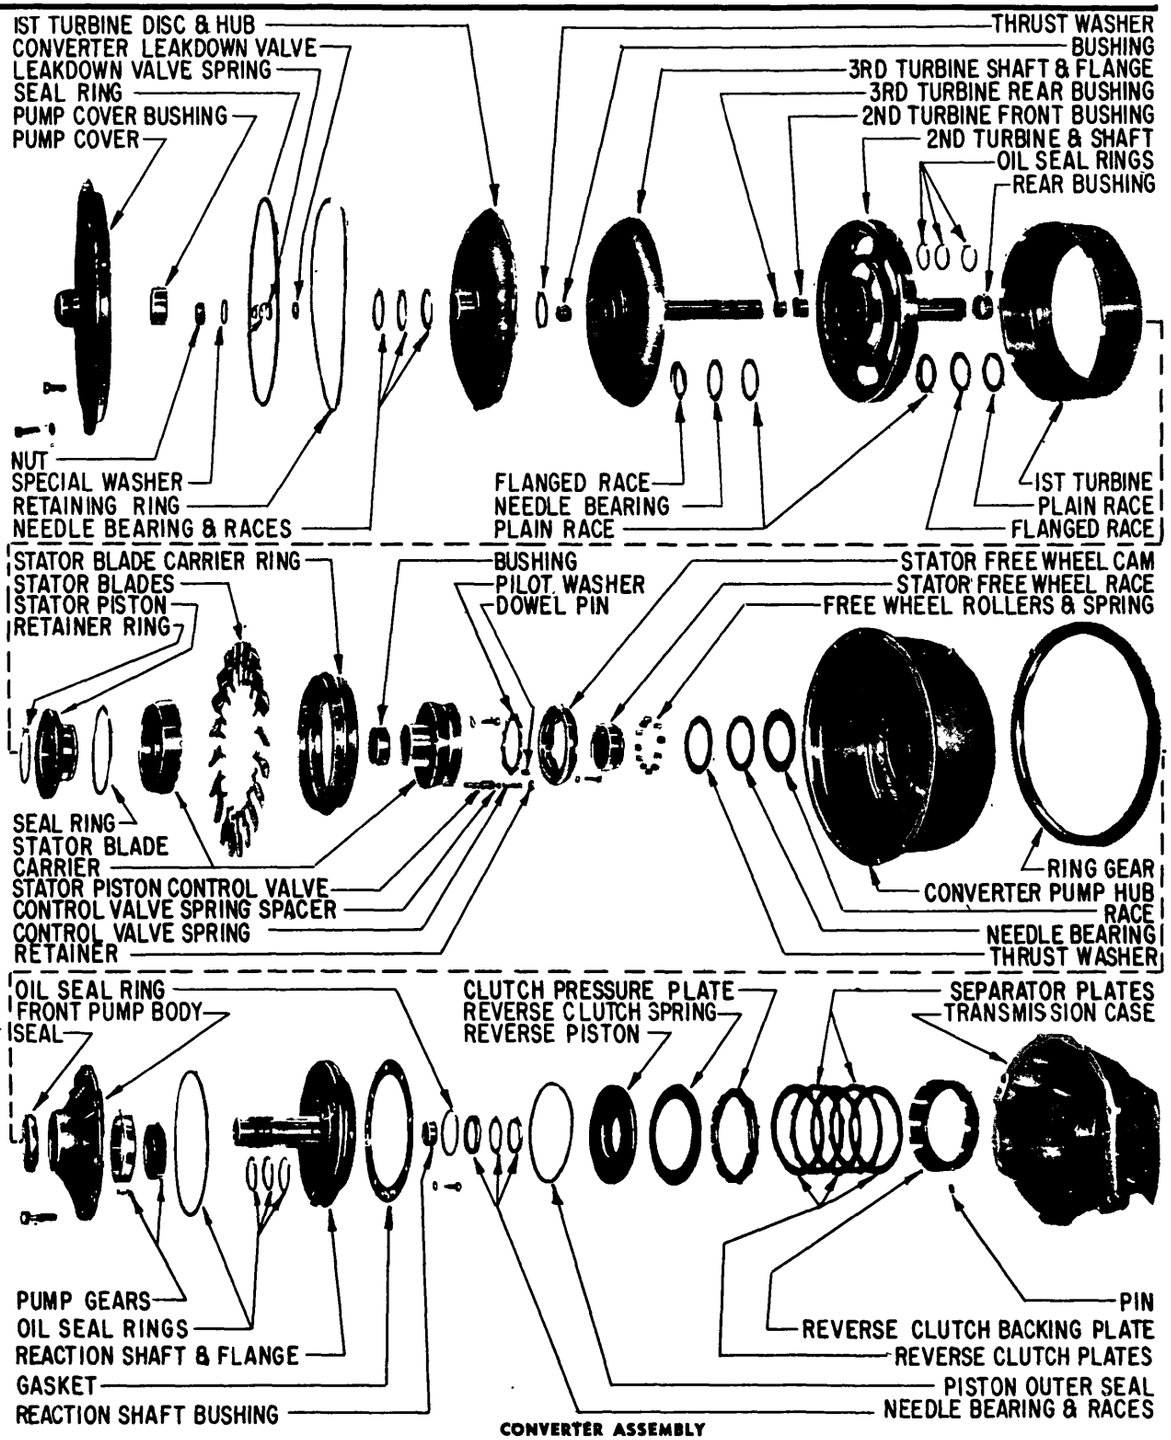
Flight Pitch Stat r R ass mbly: If stator piston control valve was removed because of a sticking or weak spring, gauge position of valve as follows: Assemble stator piston (shoulder up), to rear carrier and press together, then insert valve in bore of rear carrier. Insert Gauge J-7116 in stator control valve. With piston held against carrier and tool in place, top of tool should be flush with boss of stator rear carrier. If gauge is below surface of rear carrier, add shims to bring gauge as close to flush with surface as possible (shims are available in .007" and .021" thicknesses). Total thickness of shims used should not exceed .042". If thicker shims required, rear carrier, piston, or stator valve may require replacement. After stator valve has been checked and shims added if necessary, assemble valve, **new service spring** and retainer to stator rear carrier. *NOTE - If it was necessary to add or remove ld shims, discard ld spring and r place with a new SERVICE SPRING, Part N . 1185532. N v r use old spring when shims ar to b add d or removed.* Make sure shims are lying flat, then tap valve retainer into stator carrier squarely and flush with carrier surface (not to exceed .010" below surface). Use a flat tool for driving retainer to prevent cocking. Insert stator piston ring in bore of stator front carrier (gap should be .090" ± .010"). *NOTE - This gap serves as a pist n bleed hole for stator piston.* Expand and install stator piston ring, then install piston and ring into front carrier by tilting and inserting gap side of ring first, then pressing in. Place stator front carrier assembly and piston on stator free wheel cam an pilot washer assembly to hold piston "in". Support edge of stator blade ring and insert blades into carrier and piston assembly. *NOTE - H l s in ut r stator blad ring must be d wn when blades install d.* To install last blade, crowd several adjacent blades together to make suf-

VALVE BODY ASSEMBLY

CONTINUED ON NEXT PAGE

FLIGHT PITCH DYNAFLOW (C nt.)

ficient room. With stator blades at extreme high angle (blades lying nearly flat), assemble rear stator carrier assembly to front assembly, noting position of dowels and dowel holes. Install five clutch head screws and lock washers and tighten to 10-12 ft. lbs., using Tool 10-167-3. Install stator piston retaining ring on stator rear carrier sleeve with tangs on retaining ring entering slots in sleeve. Move stator blades from high to low angle several times and check for free operation. If necessary to replace pilot washer on stator free wheel cam, support cam and drive washer out with a drift punch. Install new pilot washer using a plastic hammer and make sure washer is seated in bore of cam. Assemble free wheel cam and pilot washer assembly to stator rear carrier with three clutch head screws and tighten to 10-12 ft. lbs. using Tool 10-167-1. Note position of dowels and dowel holes. Insert stator free wheel clutch inner race (small diameter end up) into pilot washer and make sure inner race rotates freely in washer. Install free wheel clutch rollers and springs (roller toward narrow end of cam opening and spring at wide end). Check to see that inner race rotates freely in clockwise direction, and locks on counterclockwise rotation. Apply a heavy lubricant and install bearing race and needle thrust bearing (2¼" I.D. x 3" O.D.) on stator free wheel race (race next to free wheel rollers and spring). *CAUTION - Always assemble needle bearing race with same face toward rollers as when disassembled.*



►*NOTE: If further work is being done on transmission, set complete stator assembly aside. If converter is to reassembled, refer to "Transmission Reassembly" below.*

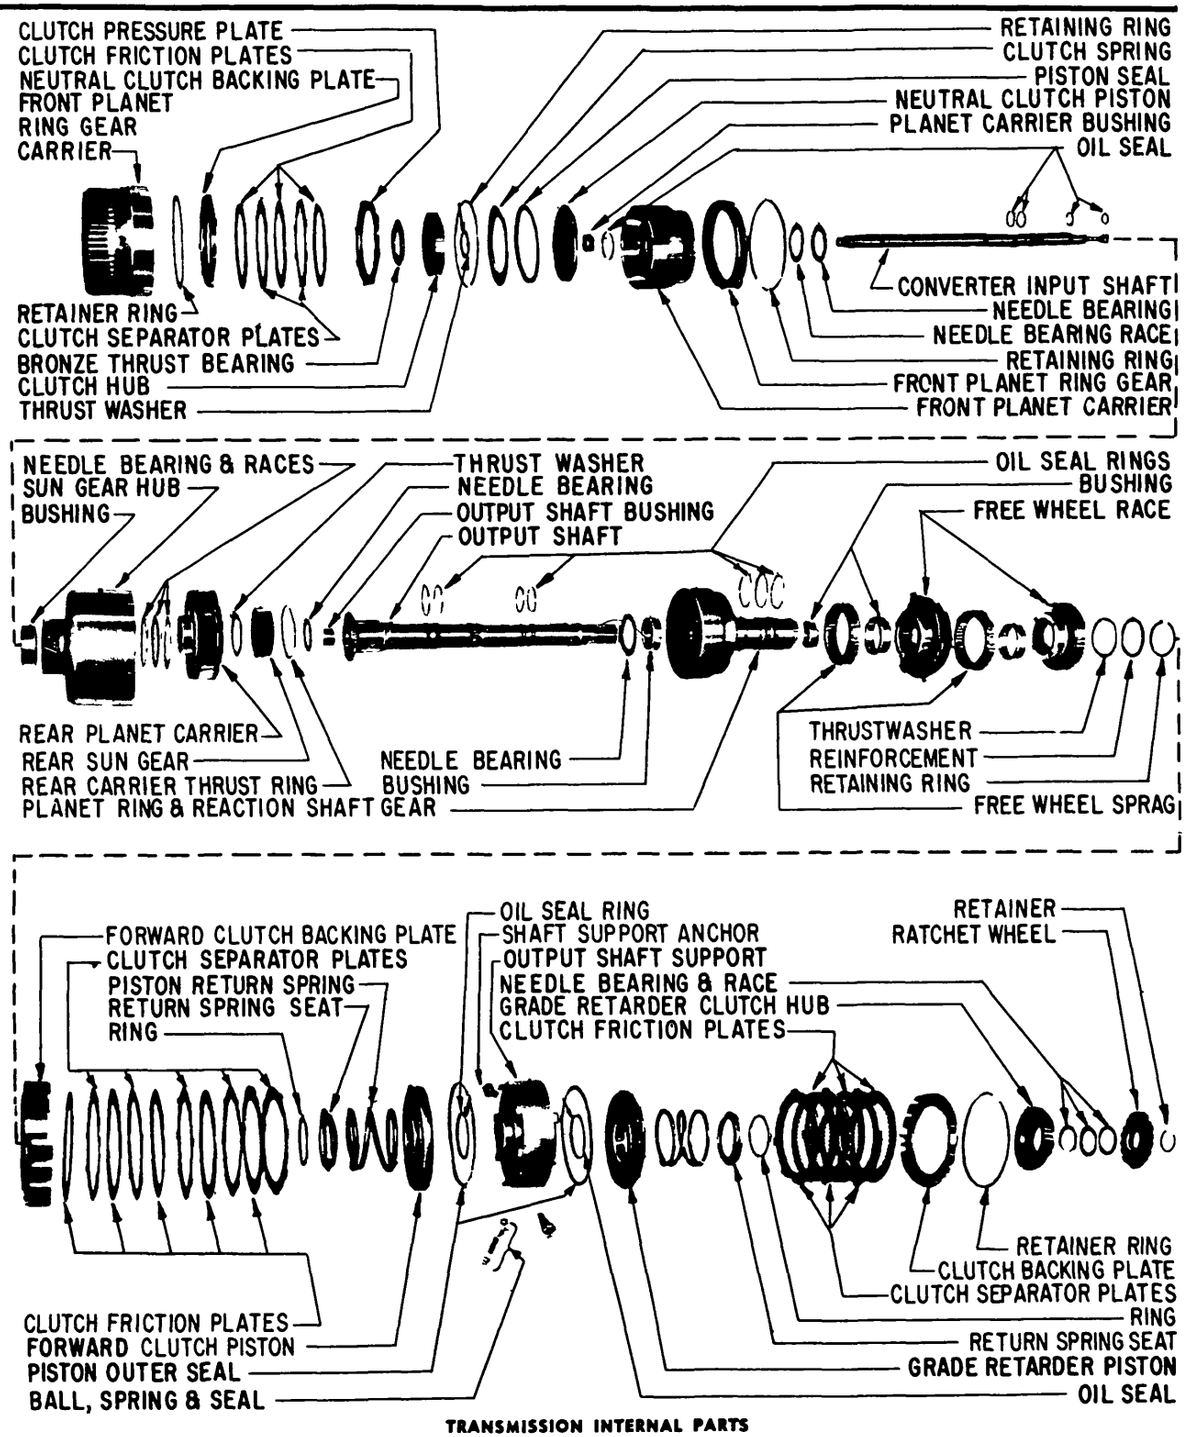
TRANSMISSION DISASSEMBLY

FRONT PUMP: Removal - With torque converter removed and transmission horizontal, remove front pump seal using slide hammer and Tool J-7005 (thread tool into seal until threads are engaged with sheet metal portion of seal). *NOTE - To install a new seal at this point, use Tool J-7006. It is not necessary to remove planet sets, first turbine shaft, and output shaft assembly to remove and install front pump seal or complete front pump-reverse piston assembly.* Remove front pump-to-case bolts, then with transmission in vertical position, install two slide hammers (Tool J-7004) in tapped holes of pump body and hammer evenly to remove pump, stator reaction shaft and flange, and reverse clutch piston assembly. Remove slide hammers.

Disassembly & Inspection: Remove needle thrust bearing and flanged rear thrust bearing race (between reaction shaft and front planet ring gear assembly). Remove reaction flange to case gasket. *NOTE - This bearing and rear race may have stuck to front planet ring gear carrier.* Remove reverse clutch piston, using pliers to grip ribs of piston if piston sticks in bore, then remove piston seal. Inspect reverse piston oil ring and if necessary to replace, assemble Tool J-7100 on ring so ring is forced solidly in groove and movable arm of tool contacts ring approximately ¼" from end. Press in on movable arm and pry up on free end of ring with small screwdriver, then release arm. With ring un-

CONTINUED ON NEXT PAGE

CONVERTER ASSEMBLY



FLIGHT PITCH DYNAFLOW (C nt.)

hooked, expand ring and remove from flange hub. *NOTE - To install new ring, rev rs r m val pro- c dur .* Remove front pump body-to-case sealing ring (square section). Inspect flanged needle thrust bearing race (between stator reaction shaft and front planet ring gear assembly). *NOTE - Bearing race is hardened and v ry brittl . Us y protection if removing with a chis l.* To install new race, use Tools J-7013-1 (handle), and J-7013-21 (installer). Remove reaction flange-to-pump body bolts and separate pump body from reaction flange by tapping assembly on bench, shaft down. Inspect, and if necessary to replace, unhook and expand the three reaction shaft oil rings, then remove from shaft. Inspect second turbine shaft-to-reaction flange bushing. If worn or scored, collapse bushing with a chisel and remove. Install new bushing with Tools J-7013-1 (handle), and J-7013-22 (installer). Using snap ring pliers, carefully expand and install new reaction shaft oil rings in grooves. *NOTE - Hold one nd f hook d ring firmly in groove and work other end of ring into position. Rotate ring in groove to check for burrs or dirt that may b present.* Check pump gear end clearance using dial indicator. Pump gears should be .001-.0025" below face of pump body. Hold drive gear away from crescent and check gap between gear and crescent with a .009" feeler gauge and then a .017" feeler gauge. The .009" gauge should "go", and the .017" gauge should "not go". If clearance not within limits (.010" - .016"), replace pump. Hold pump driven gear away from crescent and check gap between gear and crescent with a .004" feeler gauge, then with a .010" feeler gauge. The .004" gauge should "go", the .010" gauge should "not go". If clearance not within limits (.005" - .009"), replace pump. Remove pump gears by lifting straight up. *CAUTION - Protect gears against nicks, burrs, and dirt. Check front pump bushing, and if badly w rn or scored, complete pump as- s mbly must b r plac d.*

►*FRONT PUMP SEAL NOTE:* If seal is to be replaced at this point, support pump body and drive seal out.

R ass mbly: Clean and lubricate pump gears and install in body by lowering straight down. Do not use force. *NOTE - Pump drive gear must be installed with notched driving flang up, and counterbored side toward front pump s al. If new pump being installed, check driv gear on converter to be sure of proper fit.* Lubricate with Dynaflow oil and carefully assemble pump assembly to reaction shaft flange assembly. Note position of dowel pins in pump body and holes in reaction shaft flange. Install reaction shaft flange-to-pump body bolts and tighten alternately and evenly to 14-18 ft. lbs. If necessary to install new front pump seal, support assembly and drive seal into body using Tool J-7006. Install new reverse piston seal with lip away from ribbed side of piston. Lubricate reverse piston seal and install piston assembly in bore of reaction flange by running a smooth edged feeler gauge around reverse piston to keep lip of seal down. Use care to prevent damage to seal. Install new front pump body-to-case sealing ring squarely in groove of pump body. *NOTE - If further work is b ing don on transmis-*

CONTINUED ON NEXT PAGE

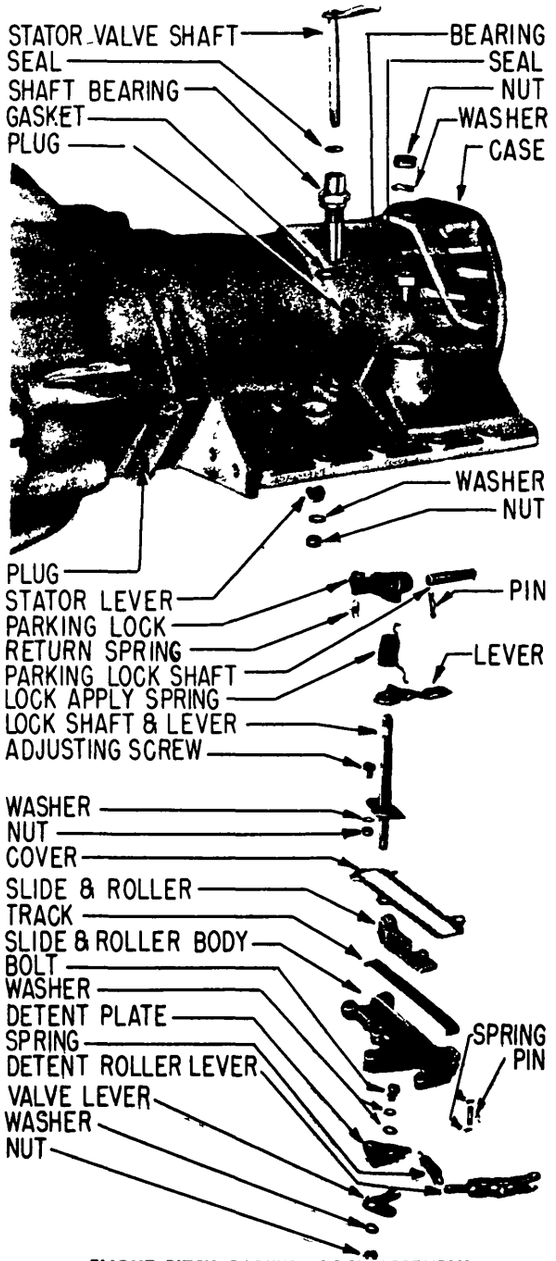
TRANSMISSION INTERNAL PARTS

FLIGHT PITCH DYNAFLOW (C nt.)

sion s t compl te pump ass mbly asid . If transmission is b ing r ass mbl d, r f r to "Transmission Reassembly" below.

VALVE BODY: Removal - With transmission upside down, remove oil pan bolts, flange reinforcement, and oil pan. Remove five oil screen screws and remove screen. Remove detent spring with needle nosed pliers, then remove sixteen valve body bolts and lock washers. *NOTE - A special washer is used on stator control stop bolt.* Remove valve body assembly and gasket carefully to avoid dropping valves.

Disassembly: Remove pressure regulator valve spring retainer and spring seat and pin using Tool J-7007. Remove manual shift valve, then remove stator control valve and stop assembly. Remove stator modulator valve and springs by rapping valve body against hand. Remove two valve body cover plate screws with a Phillips screwdriver and remove plate and gasket. Remove front and rear pump check valves and springs. Remove pressure regulator guide retaining pin by rapping valve body against hand, then remove regulator valve pin guide in same manner. Slide pressure regulator valve out of body. While holding in on retainer, remove reverse boost valve retainer pin with needle nose pliers. *NOTE - Retainer and valve will pop out when pin is r moved. Catch valve and retainer to prevent damage.* Remove reverse boost valve retainer, then remove reverse boost valve, spring, and limit valve by rapping valve body against hand. Clean all parts thoroughly and inspect for wear, scores or burrs. Pay particular attention to small holes in limit, stator modulator, and pressure regulator valve.



R assembly: Install limit valve with grooved land first, then shake valve body to seat limit valve in proper position. *NOTE - Limit valve and stator modulator valves are the same length and are interchangeable.* Install reverse booster valve spring (longer than stator modulator valve spring), then install reverse booster valve (narrow land first). Insert reverse booster valve retainer, then depress against spring tension and install reverse booster valve retainer pin flush with surface of valve body. Insert pressure regulator valve into valve body (small end first), then insert pressure regulator valve pin guide so end is flush with edge of valve body. Install pressure regulator valve pin guide retaining pin into valve body and groove of pin guide. Insert stator modulator valve into valve body (grooved land first), then shake valve body to seat valve in proper position. Install stator modulator valve springs into valve body (shorter than reverse booster spring), then install stator control valve and stop assembly. Install shift control valve (slotted end out), and insert pressure regulator valve pin and spring seat into pin guide. Install pressure regulator valve spring and spring retainer using Tool J-7007. Before tightening retainer bolts, check clearance between spring seat and retainer with a .010" feeler gauge. Spring and seat must rotate and move in retainer without touching retainer. Install check valve springs and check valves (step sides of valves toward springs). Make sure surface of valve body is clean and there are no burrs, then install new valve body plate-to-valve body gasket. *CAUTION - Mak sure pr ssur r gulator valv pin guid retaining pin is in plac .* Install valve body plate with two Phillips head screws, making sure that check valves are correctly positioned and operate freely. Check to see that valve body plate gasket lines up with holes in valve body. Pour a small amount of solvent on check valves. If valve leaks, it is burred or worn and should be replaced. *NOTE - If further work is being done on transmission, set valve body aside. If transmission is being reassembled, refer to "Transmission Reassembly" below.*

TORQUE BALL & UNIVERSAL JOINT: Removal - Remove torque ball retainer bolts, then remove outer torque ball retainer and remove torque ball. Remove sealing ring from outside of inner torque ball retainer, then remove inner retainer. Remove sealing ring from inside of retainer. Engage parking lock pawl and, using a ¾" thin wall socket, remove special drilled U-joint bolt, lockwasher, and plain washer. Remove U-joint and speedometer gear assembly.

MANUAL CONTROL & PARKING LOCK: Removal - Remove transmission lever shaft nut and remove lever. *CAUTION - Hold lever with hand while loosening or tightening nut to prevent damage to internal parts.* Remove parking lock pawl return spring using needle nose pliers, then remove parking lock and detent assembly bolts and remove the assembly. Pry selector shaft seal out of transmission housing.

Disassembly & Inspection: Parking Lock & Detent - Remove slide and roller with slide and roller cover, then remove slide and roller track. Remove manual control shaft lower nut and remove bolt holding detent plate to manual control valve operating lever. Remove shaft and parking lock lever assembly from parking lock slide body. Remove hair pin retainer from detent roller lever pin and remove pin and roller lever. Clamp lower flats of parking lock lever shaft in a vise, then rotate lever against spring tension and remove nut from parking lock lever adjusting screw. Remove screw. Rotate lever to release spring tension and pull pin from shaft. Remove spring and parking lock apply lever.

Reassembly: Parking Lock & Detent - Assemble spring on shaft with parking lock release lever positioned next to parking lock apply lever (offset of release lever should be toward apply lever), then install roll pin (hold shaft in soft jawed vise). Clamp lower flats (short end of shaft) in a vise, then raise and rotate release lever against spring tnesion and install parking lock lever adjusting screw, lockwasher, and nut (do not tighten). Assemble roller lever to slide body with pin and hairpin retainer. Assemble parking lock and shaft lever assembly to parking lock slide body. Assemble manual valve operating lever, then detent plate and shaft (bolt hole slot in detent lever must be closest to left side of detent plate). Install bolt, flat washer, and lockwasher (detent plate-to-manual control valve operating lever). Install lower nut and lockwasher on manual control shaft. Install slide and roller track in groove in slide body, then install slide and roller cover into slide body. Rotate shaft and move slide and roller so slot in lever engages pin of slide and roller. *NOTE - If furth r work is to b don on transmissi n, s t this ass mbly asid . If transmission is b ing r assembled, refer to "Transmission R ass mbly" below.*

FLIGHT PITCH PARKIN LOCK ASSEMBLY

assembled, refer to "Transmission R ass mbly" below.

►*PARKING LOCK PAWL & SHAFT NOTE:* If these parts require replacement, remove spring pin from parking lock pawl shaft and slide shaft rearward, then remove pawl.

CONTINUED ON NEXT PAGE

Form 60 A

FLIGHT PITCH DYNAFLOW (C nt.)

REAR BEARING RETAINER & REAR OIL PUMP: R - moval - Remove bolts retaining rear bearing retainer to transmission case. *CAUTION - A spacer and shim forward f r ar b aring ride on a shoulder of output shaft. This spac r and shim will fall off output shaft and lodg in r ar b aring r tainer between rear bearing ahd r ar oil pump if L ading Tool J-7012 is not used.* Insert Loading Tool J-7012 in end of output shaft and hold tool forward while sliding rear bearing retainer and rear oil pump assembly away from case. *NOTE - Shim and spac r will b transferred from output shaft to l ading tool in r ar b aring retainer.* Remove gasket. If rear bearing retainer and/or rear oil pump are not to be inspected or repaired, leave loading tool in place and set assembly aside.

Disass mbly: Remove rear oil pump to bearing retainer bolts, then remove Loading Tool J-7012 from bearing retainer assembly. Separate oil pump body from bearing retainer by supporting assembly by oil pump and striking rear flange of rear bearing retainer (do not strike gasket surface). Remove pump and gasket. *CAUTION - Fr nt face f r ar b aring retainer is a highly sensitive gask t surfac and must be carefully protected from nicks or scratch s.* Remove oil pump cover-to-body bolts and separate pump cover from body (rap two dowels with a drift if necessary), then lift pump gears straight out. Check all parts for wear, scores, or nicks. If rear pump body bushing is worn or scored, drive bushing out using Tool J-7013-1 (handle), and J-7273-8 (remover). Install new bushing in body using J-7013-1 (handle), and J-7273-6 and 11 (installer). Counterbore on J-7273-6 should be toward handle. Check rear pump end clearance with a dial indicator. Gears should be .001-.002" below surface of pump face. Use a feeler gauge and check clearance between crescent and gears. Clearance for drive gear should not be more than .006-.012"; and for driven gear, not more than .0045-.012". Replace pump if necessary. *NOTE - Reinstall g ars in pump body, align dowel holes and pins and ass mbl body to cov r. Tighten bolts to 20 ft. lbs.* Remove select fit shims and spacer from rear bearing retainer. Check rear bearing. If replacement required, pry out bearing lock, support bearing retainer web with chamfered edge of Tool J-7077 and drive out bearing with a hammer and drift (drive from front to rear). *CAUTION - R ar bearing races will be damaged during r moval and b aring must not be reused.* Install new bearing with Tool J-7013-1 (handle) and J-7013-24 (installer). Install rear lock by prying in on one end of ring in drain slot and forcing ring down into groove with another screwdriver. *NOTE - Do not install r ar oil pump until output shaft endplay has been ch ck d and adjust d within limits.*

►*REAR BEARING RETAINER REASSEMBLY NOTE: S "Transmission R assembly" below.*

MAIN DRIVE ASSEMBLY: Removal - Remove rear oil pump drive pin and if worn or damaged, discard it. Remove three adapter sleeves from control valve assembly mounting using Adapter Sleeve Tool J-6586 (retaining rings and "O" rings should be removed with adapter sleeves). Remove fourth adapter sleeve with "O" rings at cooler return pipe location next to anchor bolt location. *NOTE - Th r is n r taining ring on this adapt r.* Remove one output shaft support anchor bolt (forward of right machine locating pad on outside of case), then remove the other anchor bolt located forward of ratchet wheel inside of case. Remove retaining ring behind grade retard clutch backing plate using a screwdriver to pry ring out of groove in transmission case. To aid in removal, carefully pry front sun gear hub from front planet ring gear and carrier assembly. Install Slide Hammer, Tool J-2619-A, and Adapter, Tool J-8117, in rear end of output shaft and hammer sharply to start grade retard clutch, output shaft support, forward clutch, free wheel clutches, rear planet set and front sun gear out of transmission case. After assembly has been moved part way with slide hammer, remove slide hammer and lift from case. Remove first turbine shaft and front planet assembly (neutral clutch assembly). Remove needle thrust bearing and cupped race (front planet ring gear carrier-to-reaction flange hub). *NOTE - This bearing and race may have been removed with front pump assembly, and first turbine shaft may have been removed with output shaft.* Remove reverse clutch spring, pressure plate, and clutch plates. *CAUTION - Reverse clutch backing plate cannot be satisfactorily removed.*

Disassembly: Neutral Clutch & Front Planet Set - Slide first turbine shaft rearward out of neutral clutch and front planet set assembly (if it was not removed with output shaft). Examine, and if necessary, remove and replace four new oil rings (two butt type rings and two hooked rings) on first turbine shaft. *NOTE - The two butt type rings at rear of first turbine shaft, on early production cars, have been changed to hooked type rings on later cars. To prevent possibility of the cast iron sealing rings breaking during assembly on cars with early type input shaft, a locator ring, Part No. 1186536 has been released. This ring centralizes sealing rings in groove by not allowing them to drop down and catch during installation. Install rings in both grooves at rear end of shaft.* Remove front planet set ring gear retaining ring from groove in front ring gear carrier, then remove ring gear from carrier. Invert assembly and remove ring gear carrier from neutral clutch and front planet set assembly. Check clearance in neutral clutch pack using a dial indicator with Support, Tool J-1013, resting on hub. Set plunger of dial indicator on backing plate, then force plate down with fingers and note reading. Force plate pack up with screwdriver between neutral clutch spring snap ring and pressure plate and note clearance which should be .010-.060". Remove neutral clutch hub, needle thrust bearing assembly and tanged bronze thrust washer from neutral clutch and front planet assembly. If necessary to replace needle bearing assembly, pry out with a small screwdriver. To install a new needle bearing, use Tool J-7013-1 (handle), and J-7013-23 (installer). *CAUTION - Be sure thrust bearing is installed squarely and that it operates freely.* Remove retaining ring from neutral clutch backing plate-to-front planet set carrier by prying ring out of groove in carrier. Remove neutral clutch backing plate, clutch plates and pressure plate from planet set carrier. Remove retaining ring (neutral clutch-to-carrier) by prying it out of groove. *NOTE - This ring is th sam as neutral clutch backing plat r taining ring.* Remove neutral clutch spring from front planet carrier, then remove neutral clutch piston and seal assembly, and clutch piston rubber sealing ring. Check neutral clutch piston inner oil ring and replace if necessary. Remove needle thrust bearing and race from rear of front planet carrier. Check front carrier bushing, and if worn or scored, drive bushing out with Tool J-7013-1 (handle), and J-7273-13 (remover). Install new bushing using Tools J-7013-1 (handle), J-7273-6 (counterbore toward handle), and J-7273-14 (installer). Drive bushing out toward rear. To install, drive through front of carrier. If necessary to replace neutral clutch piston inner oil sealing ring, expand and install ring on hub of planet carrier. *NOTE - Front planet carrier and pinion assembly are servic d only as a complete unit.* Check pinions and bearings. If parts are worn or damaged, the complete unit will have to be replaced.

Reassembly: Neutral Clutch & Front Planet Set - Install new neutral clutch piston sealing ring with lip away from hub. Lubricate and install neutral clutch piston and seal in bore of front carrier using a smooth feeler gauge to aid entry of seal lip. Be careful not to damage seal during installation. Install neutral clutch spring on top of piston with outer "high" edge upward, then install clutch spring retaining ring by starting one end into groove (use plastic hammer and drift to force remainder of ring into groove). Install clutch plate pack with rounded face of pressure plate toward spring, then lubricate and install friction plate, separator plate, etc., until the three friction plates and two separator plates are installed, then install chamfered face of clutch backing plate "up" and on top. *NOTE - New clutch friction plates are .083-.087" thick.* After sticking bronze thrust washer to hub and needle bearing assembly with a heavy lubricant, line up grooves of friction plates and install hub in bore of front carrier (needle bearing up). When neutral clutch hub is correctly installed it will be below chamfered edge of neutral clutch backing plate. Install neutral clutch retaining ring in groove in front planet set carrier above backing plate, tapping it solidly into groove with a drift. Check clearance in neutral clutch pack by using a dial indicator with Support, Tool J-1013, resting on hub. Set plunger of dial indicator on backing plate, then force plate down with fingers and note reading. Force plate back up with screwdriver between neutral clutch spring snap ring and pressure plate, and note reading. Difference between the two readings should be between .010" and .060". Install front ring gear carrier over neutral clutch and carrier assembly, then invert the complete assembly. Mesh ring gear with carrier and install in carrier with tangs up. Install ring gear retaining ring and tap into groove of ring gear carrier. Apply a heavy lubricant to needle bearing race and needle bearing (1¾" I.D. x 2 7/16" O.D.) and insert race, then bearing into bore of front planet set. Press down to seat. *NOTE - There is no race on top of needle b aring as front sun g ar acts as rac .* Invert the assembly, then examine and if necessary, apply heavy lubricant to new cupped needle bearing race and install on front planet ring gear carrier. *NOTE - This*

CONTINUED ON NEXT PAGE

Form 50 B

FLIGHT PITCH DYNAFLOW (C nt.)

rac may hav r mained on r ar f stator ass mbly when transmission disassembled.

Disassembly: Output Shaft Assembly - Expand and remove parking lock ratchet wheel retaining ring, then slide grade retard clutch backing plate and clutch pack off clutch hub and output shaft. Remove parking lock ratchet wheel and grade retard clutch hub (needle thrust bearing and two bearing races will come off output shaft with grade retard hub). Slide output shaft support, forward clutch piston and grace retard piston assembly off output shaft. Slide forward clutch backing plate and clutch pack off forward clutch hub and output shaft, then separate front planet set sun gear and hub from tangs of front inner and rear outer free wheel race by prying with a screwdriver. Remove sun gear and hub. Remove needle thrust bearing (between rear sun gear and output shaft). *NOTE - Separate bearing races are not used at this point.* Slide output shaft forward through grade retard reaction shaft and remove needle thrust bearing. *NOTE - Separate bearing races not used at this point.* Inspect output shaft bushing and if worn or scored, pull bushing using Tool J-7373-15. Place output shaft in a vise with soft jaws, then slip puller into position in shaft and expand puller by holding shaft with ½" wrench and turning 5/8" nut on tool. Turn 1¼" nut on tool to pull bushing. To install new bushing, use Tool J-7013-1 (handle), and J-7273-19 (installer). If necessary to replace oil rings on shaft, unhook, then expand rings and remove. Install new rings in shaft grooves by expanding the rings. Blow compressed air through rear end of shaft to clean out small oil bleed hole and screen in shaft. If necessary to install needle thrust bearing (output shaft-to-grade retard reaction shaft), coat new bearing (1¾" I.D. x 2½" O.D.) with heavy lubricant and install on shaft.

Disassembly: Output Shaft Support - Use Tools J-2590-12 and J-2590-14 to compress forward clutch spring, then from side of output shaft support having eight lugs, remove forward clutch piston spring retainer ring with snap ring pliers. Remove tools, retainer ring, spring seat, and forward clutch piston from support. Remove rubber outer seal ring from forward clutch piston. Reinstall Tools J-2590-12 and J-2590-14 and compress spring. From side of output support having four lugs, remove grade retard spring retainer ring using snap ring pliers. Remove tools, retainer ring spring seat, spring, and grade retard piston. *NOTE - A wide chamfer in I.D. of forward clutch piston and no chamfer in I.D. of grade retard piston will identify these two parts at reassembly.* Remove rubber oil seal ring from grade retard piston. If necessary to replace forward clutch inner oil ring, assemble Tool J-7086 so forward clutch inner oil ring is forced solidly into groove. Press down movable arm of tool and pry free end of hooked oil ring out with screwdriver. Release movable arm of tool, then expand and remove oil ring from output shaft support. Install new oil ring using same tool as for removal. If inner oil ring in grade retard clutch piston must be replaced, use same procedure as for forward clutch piston. Use a hook made of stiff wire and pull lubrication pressure regulator spring retainer, spring, and ball from output shaft support. *NOTE - If output shaft bushing is xcessiv ly w rn r sc red, it will be nec ssary t replac th utput shaft supp rt ass mbly.*

Reassembly: Output Shaft Support - Inspect lubricating pressure regulator ball and replace if worn or scored. Install ball, spring, retainer (with small hole down) in hole of output shaft support. Drive retainer flush with surface of support to .010" below, with plastic hammer. Install new rubber sealing ring on forward clutch piston (piston has a wide chamfer in bore), then lubricate and use a smooth feeler gauge to hold lip of rubber ring down while inserting piston into support. Install a new rubber sealing ring on grade retard piston, then install piston in same manner as for forward forward clutch piston (above). Install forward clutch spring, retainer, and snap ring using Tool J-2590-12 and J-2590-14, and snap ring pliers. *NOTE - Grade retard retainer and snap ring are interchangeable with forward clutch spring, retainer, and snap ring.* Install grade retard clutch spring, retainer and snap ring in same manner.

►*FRONT PLANET SET SUN GEAR HUB BUSHING REPLACEMENT:* Remove and install bushing in hub with Tools J-7013-1 (handle), and J-7273-10 (remover). Counterbore on Tool J-7013-6 must be toward handle.

Disassembly: Rear Planet Set - Remove planet set carrier needle thrust bearing and bearing races from hub of carriers. Grasp carrier and slide carrier and planet assembly out of rear planet set ring gear. *NOTE - It may be necessary to pry assembly apart.* Pry rear carrier thrust ring out of groove in carrier and remove ring. Remove rear planet set sun gear and tanged bronze thrust washer (between rear sun gear and rear planet carrier). *NOTE - Rear planet carrier and pinion assembly is serviced only as a complete assembly.* Check planet pinions for scoring or chipping. Check planet pinion bearings for smooth operation. If gears or bearings are not serviceable, replace rear planet carrier assembly.

Reassembly: Rear Planet Set - Inspect and if necessary, replace planet set sun gear thrust washer. Apply heavy lubricant to thrust washer and position in carrier with tangs down into holes in carrier. Install sun gear with either end up, then install thrust ring solidly in groove above sun gear.

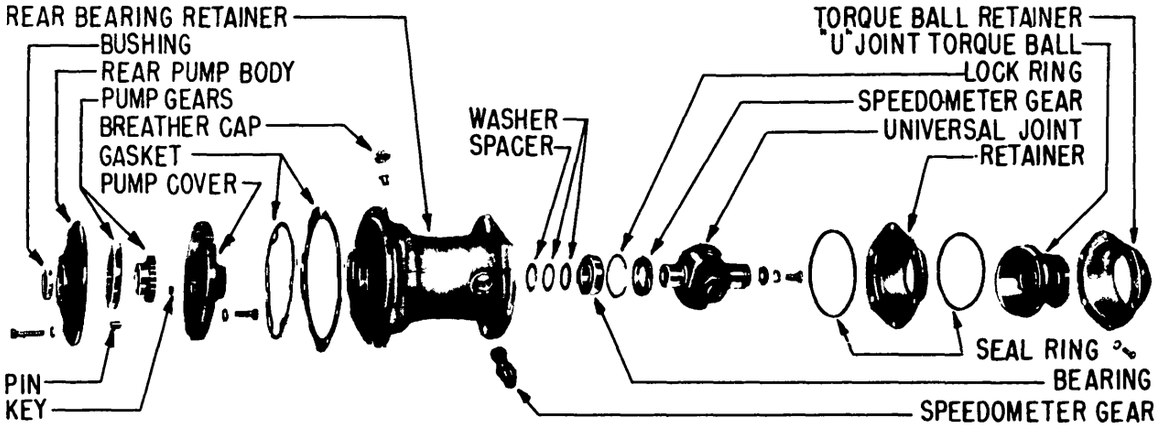
Disassembly: Free Wheel Clutch & Reaction Shaft - Expand and remove rear free wheel inner race-to-grade retard reaction shaft retaining ring, then remove rear free wheel clutch inner race thrust washer and spacer (between rear free wheel race and retaining ring). Rotate race clockwise and slide sprag and race out of rear free wheel outer race. Remove and inspect sprag. Inspect rear free wheel clutch inner race bushing and if worn or scored, drive bushing out using Tool J-7013-1 (handle), and J-7273-4 (remover). Install new bushing, using Tool J-7013-1 (handle), J-7273-5 and J-7273-6 (counterbore on J-7273-6 toward handle). Rotate front inner and rear outer free wheel clutch race clockwise and slide race and sprag out of rear planet ring gear (front free wheel clutch outer race). Remove and inspect sprag. *NOTE - Front wh l sprag has an inn r cag 1/32" long r than ut r cag and is n t int rchangeabl with r ar sprag.* Inspect front inner and rear outer free wheel clutch race bushing. If worn or scored, drive bushing out with Tool J-7013-1 (handle), and J-7273-4 (remover). Install new bushing with Tool J-7013-1 (handle), J-7273-4 and J-7273-6 (counterbore on J-7273-6 toward handle). If necessary to replace the three oil rings on grade retard reaction shaft, expand and remove rings, then install new rings in grooves and hook the ends. Inspect front grade retard reaction shaft bushing. If worn or scored, assemble Tool J-7003-1 (guide pin) to J-7273-9 (remover), then tilt tool and insert behind front bushing, using Tool J-7003-1 as a handle to hold Tool J-7273-9 in place across bushing. Insert J-7013-1 (handle) through rear of reaction shaft to enter J-7273-9 (remover) and drive out bushing. Install new bushing with Tool J-7013-1 (handle), J-7273-6 and J-7273-8 (counterbore on J-7273-6 toward handle). If rear bushing in grade retard reaction shaft is to be replaced, drive out bushing using Tool J-7013-1 (handle) and J-7273-7 (remover). Install new bushing with Tool J-7013-1 (handle), J-7273-6 and J-7273-7 (counterbore on J-7273-6 toward handle).

Reassembly: Free Wheel Clutch & Reacti n Shaft - Slip front sprag into front free wheel clutch outer race with shoulder of sprag up toward reaction shaft. *NOTE - Front free wheel clutch sprag has an inn r cag 1/32" longer than outer cage and n bronz drag strips. B careful not to interchang with rear sprag.* Insert front free wheel clutch inner race into sprag while rotating clockwise. Race must rotate freely on clockwise rotation and lock on counterclockwise rotation. When correctly installed, front inner free wheel race will be approximately 1/16" from front outer race. Insert rear free wheel clutch sprag into rear outer race with shoulder on sprag up toward reaction shaft. *NOTE - Rear free wheel clutch sprag has three bronz drag strips at lower edge.* Insert rear free wheel clutch inner race (forward clutch hub) into sprag while rotating clockwise. Inner race must rotate freely on clockwise rotation and lock on counterclockwise rotation. When correctly installed, rear free wheel inner race should contact front inner (rear outer) race. *CAUTION - If approximately 1/8" clearanc xists, r ar inn r rac may be hanging up on bronz strip at bott m f sprag assembly.* Assemble new free wheel clutch inner race thrust washer first, then reinforcement and retainer ring on grade retard reaction shaft. Expand and install retaining ring solidly in groove of reaction shaft.

Reassembly: Output Shaft Ass mbly - With needle thrust bearing in place on output shaft, slide free wheel clutch assembly over output shaft and into position against needle thrust bearing. *NOTE - Rac s n t us d at this location.* Apply heavy lubricant to output shaft-to-rear planet sun gear needle thrust bearing (1 3/16" I.D. x 1 7/8" O.D.) and set on forward end of output shaft. *NOTE - Races not us d at this l cation.* Insert rear planet sun gear assembly into rear planet ring gear assembly. Apply heavy lubricant to rear planet-to-front sun gear needle bearing and two bearing races and position on hub of carrier. Install front planet set sun gear and hub over front of rear planet set and free wheel clutch assembly. *CAUTION - D not lift ass mbly by nd f utput shaft as thrust washer and oth r parts may fall out of position. Mak this instal-*

CONTINUED ON NEXT PAGE

FLIGHT PITCH DYNAFLOW (C nt.)



lation with ass mbly in horizontal position. Make sure front planet set sun gear hub extends beyond front inner (rear outer) free wheel clutch race tangs. *NOTE- Tangs f front inn r (r ar outer) race do not seat in b tt m f sl ts in sun g ar hub.* Install forward clutch backing plate over rear free wheel clutch inner race, then lubricate a friction plate with Dynaflow oil and install it next to backing plate. Engage tangs of separator plate in narrow slots of backing plate and continue to build-up by alternately assembling a friction plate and a separator plate. *NOTE - Align notches of tangs on s parator plat s in same NARROW slot of backing plat . N tch s must all be in same slot and must all be n sam sid f same sl t in backing plate.* Lubricate and install output shaft support assembly on output shaft (eight lugs down, and four lugs toward end of output shaft). Engage eight lugs in wide slots of forward clutch backing plate. Install grade retard clutch hub, needle thrust bearing (1½" I.D. x 2 3/16" O.D.) and two thrust bearing races (one on each side of needle thrust bearing). Slip on parking lock ratchet wheel and install retaining ring solidly in groove of output shaft.

TRANSMISSION REASSEMBLY

MAIN DRIVE ASSEMBLY: Reverse Clutch Pack - Check for direction of "dish" on both clutch separator plates. *NOTE - Friction plat s are .098" to .102" thick when new.* With transmission front end up, lubricate and install a reverse clutch friction plate in reverse clutch backing plate, then a separator plate (with "dish" in either direction), then another friction plate, followed by a separator plate (with "dish" in same direction as first separator plate), then install last friction plate. Install reverse clutch pressure plate (rounded edge up) and reverse clutch spring (with center high edge up).

Fr nt Pump (R action Shaft): Install new front pump-to-case gasket in transmission case, making sure that gasket holes line up properly. Install two 3/8"-16 Guide Pins, Tool J-7003 in transmission case, then lubricate rubber seal on front pump assembly with a heavy lubricant and slip front pump and reverse clutch piston assembly into transmission case so that the three closely spaced holes are at bottom of case. Tap assembly evenly and solidly into position with a brass drift and a plastic hammer. *CAUTION - Do not attempt to draw front pump assembly into position with front pump bolts as transmission case threads will almost certainly b stripped.* On early cars, install lockwasher, flat washer, and sealing washer on front pump-to-case bolts. *NOTE - On lat r cars, front pump bolts are equipped with captiv sealing lockwashers.* Install at least two front pump-to-case bolts and check reverse clutch pack clearance with feeler gauge between any two plates. Clearance should be .007-.055". If more than .055", friction plates should be replaced. Remove guide pins and install all bolts to 30-35 ft. lbs. after preliminary tightening by criss-crossing from one bolt to another.

N utral Clutch Ass mbly: With transmission upside down, apply a heavy lubricant and install needle thrust bearing (1¾" I.D. x 2½" O.D.) in cupped bearing race at rear of stator reaction shaft. Install neutral clutch assembly into case being certain cupped bearing race is in position on hub of front planet set ring gear carrier (front of neutral clutch assembly). *CAUTION - When installing neutral clutch assembly into reverse clutch pack, rotate neutral clutch assembly to line up splines and allow front planet ring gear carrier assembly hub to seat against needle thrust bearing. Hole in front ring gear carrier will be nearly even with edge of opening in transmission case when assembly is seated against needle thrust bearing.*

FLIGHT PITCH DYNAFLOW REAR BEARING RETAINER & TORQUE BALL ASSEMBLY

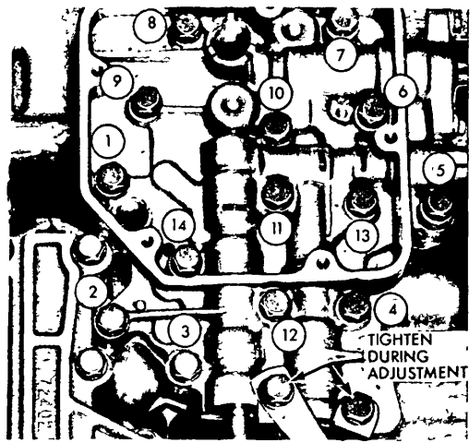
►*PARKING LOCK PAWL NOTE:* If parking lock pawl and shaft were removed, install these parts and retain in place with hairpin clip.

Output Shaft Assembly: Lubricate oil rings on first turbine shaft, then rotate shaft to line up splines and insert in output shaft assembly until last oil ring is inside front planet set sun gear. Start first turbine shaft and output shaft assembly (first turbine shaft first) into rear of transmission case. Guide front of first turbine shaft through neutral clutch assembly, then push into case until forward clutch backing plate is just entering rear of case. *NOTE - Check forward clutch backing plate to be certain it is in contact with output shaft support, and that clutch plates are properly positioned in slots of backing plate and that oil sleeve holes in support are lined up.* Check three grade retard clutch separator plates for "dish". *NOTE - Separator plates may be installed with "dish" in either direction but all must be installed the same way.* Install separator next to grade retard piston with center tang (of three tangs) between lugs of support, then friction plate, separator plate, and continue until three separator plates and three friction plates are installed. *NOTE - Grade retard clutch friction plates are .075-.080" thick when new.* Lubricate plates with Dynaflow oil, then install grade retard clutch backing plate with tangs of separator plates in NARROW slots and tangs of output shaft support in WIDE slots. Hold backing plate firmly in contact with output shaft support and slide assembly into position. *CAUTION - Maintain hand pr ssur forward on grad retard clutch backing plat at all times until assembly is correctly position d in cas and backing plate r tainer ring is install d. If backing plat is allowed to separate from support, clutch pack will fall out of position and complete assembly must be removed from case and reassembled.* While installing the assembly, it may be necessary to rotate front planet set ring gear or carrier with screwdriver to line up teeth on sun gear with front planet pinions. *NOTE - It is not necessary to force assembly into place. Assembly is correctly positioned in case when grade retard clutch backing plate retaining ring can be installed in groov in transmission case.* Install grade retard clutch backing plate retainer ring solidly in groove in case. Use a smooth punch inserted in anchor bolt hole to line up oil sleeve adaptor holes in support with holes in case. Do not use oil adaptor sleeves for this purpose. Lubricate and install three adaptor sleeves with new "O" rings into valve body portion of transmission case using Tool J-6586. Push down firmly to seat adaptor sleeves in output shaft support. Install retainer rings above the "O" ring sleeve assemblies using a screwdriver to seat retainer rings against sleeve assemblies. *NOTE - Center adaptor sleeve does not enter case as far as outer two.* Lubricate and install fourth adaptor sleeve with new "O" rings at oil cooler return line location using Tool J-6586 (sleeve retainer not used at this location). Install outer and inner anchor bolts and tighten to 35-40 ft. lbs., then install rear pump drive pin in output shaft.

Rear Bearing Retainer Reassembly: *NOTE - If rear oil pump was not removed from rear bearing retainer and loading tool was left in retainer, see "Rear Bearing Retainer" below.* If rear oil pump and loading tool were removed from rear bearing retainer, install .120" spacer on output shaft along with shims removed from output shaft when transmission was disassembled. Install two 3/8"-16 Guide Pins, J-7003, gasket, and rear bearing retainer (without oil pump). Check output shaft end clearance with rear bearing retainer bolted to case with at least two bolts and transmission upside down. Tap several times on output shaft to squeeze lubricant out of thrust bearings. Use Dial Indicator J-8001-3, Tool J-5804 threaded into output shaft and Tool J-5808 threaded into rear bearing retainer. Use a pry bar under

CONTINUED ON NEXT PAGE

FLIGHT PITCH DYNAFLOW (C nt.)



edge of Tool J-5804 to move output shaft. Endplay should be .015-.035". If less than .015", remove rear bearing retainer and install a thinner shim on output shaft. If more than .035", install a thicker shim. With endplay within limits, remove tools and rear bearing retainer from case. Insert Loading Tool J-7012 in rear of rear bearing retainer through retainer. Install two 5/16"-18 Guide Pins, Tool J-7001 in rear bearing retainer, then install new oil pump-to-bearing retainer gasket. Install oil pump, noting openings in pump and in rear bearing retainer, then install oil pump attaching bolts and tighten to 15-20 ft. lbs. *NOTE - Inspect front face of rear bearing retainer and mating surface at rear of transmission case carefully. Be sure there are no nicks or burrs that would prevent a good seal at this point.*

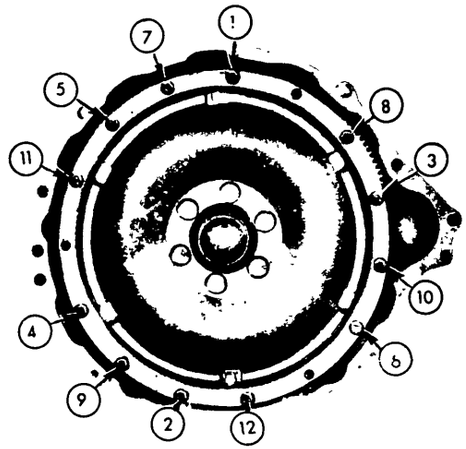
Rear Bearing Retainer: *NOTE - If rear oil pump was not removed from rear bearing retainer and loading tool was left in retainer, install retainer (see below), using two bolts, and check output shaft endplay (see "Rear Bearing Retainer Reassembly" above). If within limits, complete installation. If adjustment required, follow instructions outlined in "Rear Bearing Retainer Reassembly" above.* To install retainer assembly, install a new retainer-to-case gasket and assemble retainer to case making sure that slot in oil drive gear and driving pin in output shaft is lined up. *NOTE - If necessary to turn output shaft to line pin up with oil pump drive gear, turn parking lock ratchet wheel.* Hold loading tool forward while sliding bearing retainer onto output shaft to transfer spacer and shims onto shaft. Remove loading tool and install rear bearing-to-case bolts. Tighten alternately and evenly to 25-30 ft. lbs.

Parking Lock: Install properly assembled parking lock assembly to case with four bolts and tighten to 15-20 ft. lbs. then install parking lockpawl return spring.

T rque Ball & Universal Joint: Engage parking lock pawl and install universal joint and speedometer gear assembly with specially drilled universal joint bolt, lock washer, and plain washer using a 3/4" thin wall socket. Tighten to 50-55 ft. lbs. With transmission rear end upward, use heavy lubricant and install inner torque ball retainer sealing ring in groove of rear bearing retainer, then install torque ball retainer on rear bearing retainer. Install new sealing ring on outside of inner torque ball retainer, then liberally lubricate inside of torque ball and install over universal joint and inner torque ball retainer. Position torque ball with drain slot toward bottom of transmission case. Install outer torque ball retainer over torque ball and install bolts. *NOTE - Do not tighten bolts until transmission is installed in car.*

Valve Body: With transmission upside down, use a new gasket and carefully install valve body assembly. Engage slot in shift lever with slot and pin in manual control lever. Install bolts in valve body *(see "Valve Body Installati n Note" b low),* and install stator lever stop, using a special washer under head of attaching bolt. Tighten all valve body attaching bolts to 15-20 ft. lbs. in sequence indicated in illustration

VALVE BODY BOLT TIGHTENING SEQUENCE



(except stator lever stop and stator control valve stop attaching bolts). Check for free operation of shift control valve. *See "Control Valve & Parking Lock Adjustment" above.*

►*VALVE BODY INSTALLATION NOTE:* Three different bolt lengths used. Refer to bolt tightening sequence illustration and install the different length bolts in holes as follows: 1¼" - (No. 1, 2, 3, 8, 9, 14). 1½" -(No. 4, 5, 6, 7, 10, 11, 12, 13 and at stator control valve stop attaching location). 1¾" -(Install in stator control lever stop attaching location).

Oil Screen, Oil Pan & Selector Lever: Install oil screen, then install new oil pan gasket, oil pan, oil pan flange reinforcement, and bolts. Tighten bolts to 10-12 ft. lbs. *NOTE - Oil pan gasket must be installed with "sharp" corner of gasket at right front edge of pan flange (transmission upside down and viewed from rear).* Install selector shaft seal and selector lever.

TORQUE CONVERTER REASSEMBLY & INSTALLATION

Reassembly & Installation: *NOTE - See "First Turbine Hub and Shaft Production Change & Special Tool Note" above, then proceed as follows:* Before assembling and installing converter assembly in transmission, check converter clearance as follows: Support converter pump on wood blocks (on bench), then install needle bearing race and needle bearing. Install thrust washer and stator assembly. Install flanged needle thrust bearing race, needle bearing, and .050" thick thrust bearing race on hub of second turbine, holding it in place with heavy lubricant, then install turbine assembly into place in converter pump. Install selective fit bearing race, needle bearing, and second selective fit race of turbine assembly hub. *NOTE - S l ctiv fit b aring rac s ar availabl in .030", .040", .050" thickn ss s.* Set Converter Clearance Gauge, Tool J-5899, in place with small diameter of sleeve upward

CONVERTER COVER BOLT TIGHTENING SEQUENCE

and loosen setscrew, then push sleeve down firmly to seat and tighten screw. *NOTE - S e "Conv rter Gaug Rework For Use With Flight Pitch Transmission Torque Converter" above.* Remove gauge from first turbine hub, then invert gauge and place on converter pump cover (support cover on wood blocks). Assemble dial indicator to post and place plunger of indicator on gauge sleeve. Loosen setscrew, push sleeve down. Reading on dial indicator is total converter clearance. If indicator reading is less than .004", change selective fit bearing races to a thinner size. If indicator reading is greater than .017" change selective fit washers to a thicker size. Remove tools, then disassemble converter. To reassemble and install converter in transmission case, turn transmission case so front end is upward, then carefully install converter pump (rotate pump to engage lugs of pump hub with front pump drive gear). Install needle thrust bearing race, needle bearing (2¼" I.D. x 3" O.D.), then install stator assembly on reaction shaft. Press down and rotate stator. Stator must rotate freely clockwise and lock on counter-clockwise rotation. Install flanged needle thrust bearing race, needle bearing, and .050" thick thrust bearing race on hub of second turbine and hold it in place with heavy lubricant. Carefully lower turbine assembly into place, rotating it as necessary to align splines. Install converter leakdown valve and spring on first turbine disc hub over first turbine shaft with large end of spring toward valve. Install new special washer on first turbine shaft making sure that converter leakdown valve spring is not caught between washer and first turbine shaft. Install first turbine shaft nut and tighten to 45-50 ft. lbs. Position two selective fit plain bearing races on first turbine hub with needle thrust bearing (1¾" I.D. x 2½" O.D.) between the races. Install new "O" ring on converter pump cover and install cover on pump in same position as when removed. Install bolts and tighten in sequence indicated in illustration to 25-30 ft. lbs.

CONTINUED ON NEXT PAGE

FLIGHT PITCH DYNAFLOW (Cont.)

TRANSMISSION INSTALLATION IN CAR

Torque Converter and transmission assembly are installed as a complete unit.

1) Turn flywheel so one hole for converter attaching bolt is straight up and wide flange is straight down. *CAUTION - Be sur drive lugs on converter pump do not dis ngage from front pump gear.* Raise transmission into place with same equipment used for removal, then align converter attaching bolt holes with flywheel holes before moving transmission forward against crankcase.

2) Adjust lifting equipment so transmission meets crankcase squarely, then move transmission assembly into crankcase. Install converter housing-to-crankcase bolts and tighten evenly to 45-55 ft. lbs. Install three flywheel-to-converter bolts and tighten to 25-30 ft. lbs., then check converter drain plugs for tightness and install converter housing cover.

3) Raise transmission just enough to install transmission support, installing any shims in their original position. Tighten bolts to 25-30 ft. lbs., then install the nuts and bolts holding the mounts to support and tighten to 25-30 ft. lbs. *NOTE - If transmission can not b mad to s at on support, front engine mounts should b loosen d and engin raised (by means of a pry bar) and pulled forward to remove bind from front mounts.* Remove engine jack and transmission hoist.

4) Connect upper shift rod to idler lever and lower shift rod to transmission lever, then connect speedometer cable. Complete engine installation by reversing removal procedure.

5) With car on floor, add four quarts of Dynaflow oil to transmission, then raise rear wheels and with transmission in "Drive" range and engine idling, add eight more quarts of Dynaflow oil. Place transmission selector lever in "Neutral", lower rear wheels to ground, then check oil level and add oil as necessary to bring proper level on dipstick.

FLYWHEEL ALIGNMENT & ENGINE BALANCING

►*IF VIBRATION NOTED AFTER INSTALLATION OF TRANSMISSION, CRANKSHAFT, FLYWHEEL, OR OTHER ROTATING PART; CHECK AND CORRECT FLYWHEEL ALIGNMENT. IF VIBRATION NOT CORRECTED, BALANCE ENGINE.*

FLYWHEEL ALIGNMENT: 1) Place car on jack stands (high enough to work under), then connect a tachometer to engine and operate engine with transmission in "Park" position. Increase engine speed gradually until the objectionable vibration is apparent and note engine speed; then stop engine. *NOTE - Critical speed should be around 2200 RPM.*

2) Remove bell housing cover and loosen one flywheel-to-converter attaching bolt and note position of the flywheel spoke in relation to converter cover. Spoke should just contact cover without applying pressure against it. If clearance is above .010" (between spoke and cover with attaching bolt removed), bend flywheel toward pump cover. *NOTE - To bend flywheel spoke, insert two round metal rods ¼" in diameter and 8" long between flywheel and converter cover; then install flywheel attaching bolt and tighten to 25-30 ft. lbs.* After bending, recheck clearance. If necessary to bend spoke away from flywheel, use a screwdriver under spoke. Repeat the above procedure for all three spokes.

CONVERTER PUMP: *NOTE - The following procedure will correct minor unbalance caused by replacement of individually balanced parts. Extreme vibration caused by parts abnormally out of balance, or difference in weight from corresponding parts, should be corrected by replacement of these parts.*

1) Determine speed at which vibration is most evident (use tachometer) and operate engine at this speed to check results from the following corrective procedures.

2) Install one balance weight, Part No. 1178109 (.060" thick) under head of two converter pump cover bolts and tighten to 25-30 ft. lbs. *CAUTION - Do not place weight at a converter-to-flywheel driving bolt because of lack of clearance at this location. If weight is required at flywheel attaching bolt location, weight should be divided and installed at the adjacent two bolts at each side of attaching bolt.*

3) Run engine through critical speed range of 1200-3500 RPM and carefully compare vibration with that obtained without the weight, then stop engine. Mark location of balance weight on converter pump, remove weight and tighten bolts to 25-30 ft. lbs. Install balance weight as near 180° from original position as possible and compare with vibration produced at critcal speed. If either of these positions show improvement, move weight around near that location for further gain. If not, try weight at remaining two positions to complete trials in four directions that are 90° apart and note at what point most gain is achieved.

4) At point where balance weight produces greatest improvement in vibration, install weights of different thickness to attempt to further improve the vibration. Balance weights are furnished in the following thicknesses:

Balance Weight Part Nos.

Thickness	Part N .
.0345"	1178108
.060"	1178109
.120"	1178110

►*CAUTION: A maximum weight thickness of 1/8" must not be exceeded due to limited clearance between bolt and crankcase.*

CRANKSHAFT PULLEY: Follow the same procedure as for converter pump (see above). The first trial should consist of three flat washers, Part No. 446363 (3/8" x 7/8" x .080") placed under one driving pulley attaching bolt. *NOTE - Standard pulley attaching bolts should be replaced with a 5/16" - 18 x 1¼" bolt, Part No. 186624.* At least four of the six positions should be tried for vibration improvement. After determining general position of greatest improvement, further gains may be made by distributing the washers between two bolts or by changing number of washers used. On crankshafts with two or three groove pulley, a wad of Perma Gum (approx. ½ oz.) may be placed inside pulley cavity on inner flat surface and engine run to determine effect on balance. Mark location of weight on pulley and move in same manner as outlined above. At point where greatest improvement is noted, add or subtract weight as required to obtain best balance, then remove pulley attaching bolt and Perma Gum and install comparable weight of washers, as outlined above, with longer bolt.

1954-57 CHEVROLET POWERGLIDE

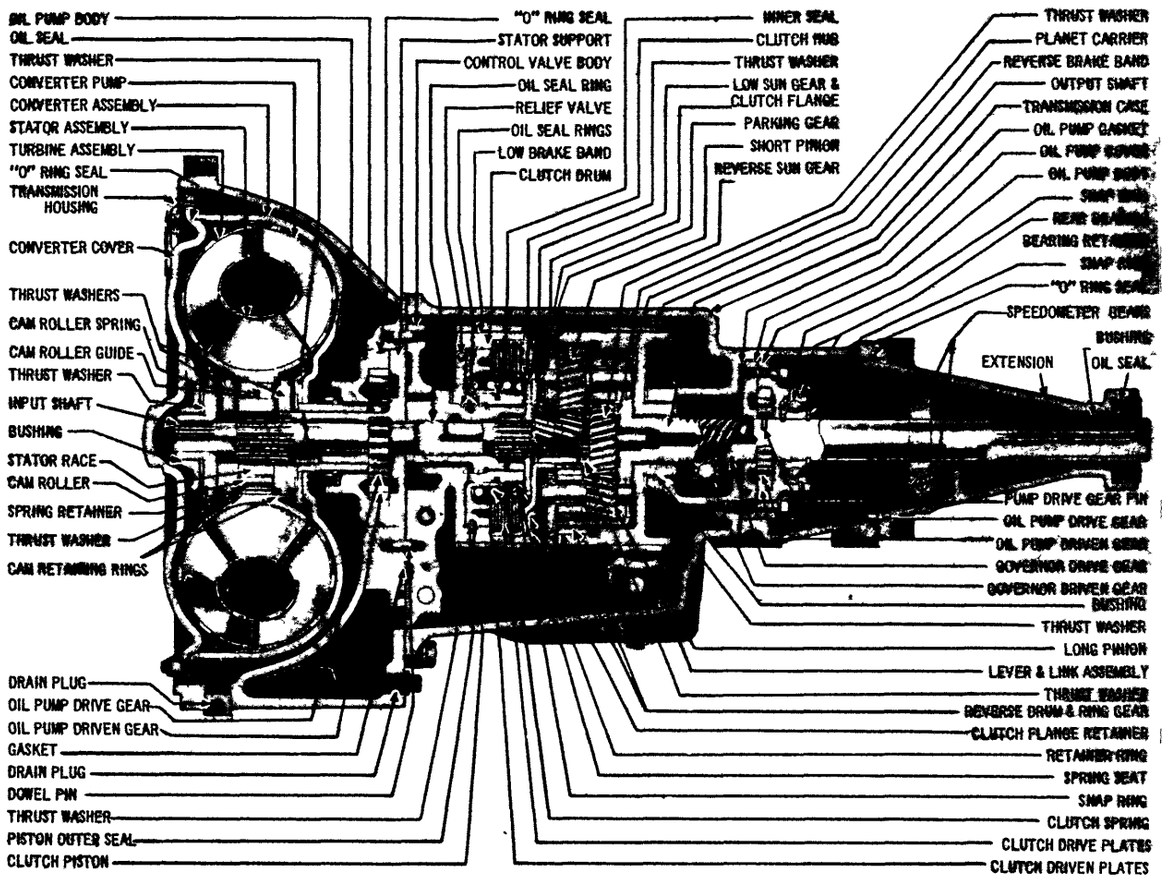
Ch vr let Pass. Cars (1954-57)
Ch vr l t Corvette (1954-57)

►CHANGES, CAUTIONS, CORRECTIONS

►*STARTING ENGINE BY PUSHING CAR (Pushing recommended rather than towing):* Place selector lever in Neutral "N" position. When car reaches speed of approximately 16 MPH. (20 MPH if road wet or icy with resultant poor traction), move selector lever to Low "L" position to crank engine. After engine is started, move lever to "N" for engine warm-up.

►***1954 CORVETTE TORQUE CONVERTER-TO-FLYWHEEL DRIVE LUG PRODUCTION CHANGE:*** Three additional drive lugs have been added to torque converter for attaching converter to flywheel. This change entered production with Corvette Powerglide Transmission No. C-409-D. These additional drive lugs can be installed on earlier cars as follows:

1) Remove transmission, being careful not to drop torque converter. Loosely attach drive lugs, Part No. 3713602 to the converter cover under the converter cover attaching nuts. Remove flywheel from engine, or take flywheel from stock and fasten flywheel to converter, using all the drive bolts, and tighten bolts securely. Tighten lug retaining nut (converter cover nuts) and remove flywheel. ***NOTE—It is necessary to install flywheel to converter to assure centering of the drive lugs and the flywheel attaching bolt holes. Do Not disturb drive lugs after removing flywheel.***



2) Reinstall flywheel to engine and transmission to car, making sure that "X" mark on converter cover and "X" mark on flywheel are aligned.

►*1955 CONTROL VALVE & GASKET PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE (To liminate a harsh closed throttle downshift):* A new control valve assembly, Part No. 3719934 *(see "Later Type Control Valve Identification Note" below),* entered production at Transmission Serial No. C-103-D. The later type control valve assembly is also furnished as a service replacement for earlier transmissions. *CAUTION - The later Valve Body & Case Gasket, Part No. 3719232, is not interchangeable with the early type gasket.*

►*LATER TYPE CONTROL VALVE IDENTIFICATION NOTE:* Transmissions with later type valve assembly are identified as follows: Between Transmission Serial No. C-103-D and C-128-N, an "X" will be stamped adjacent to casting No. 3709023 on rear surface. After Transmission Serial No. C-128-N, Casting No. 3719221 will be found on rear surface.

►*1955 CONTROL VALVE BODY & CASE GASKET CAUTION:* Early and late type gaskets are not interchangeable. These gaskets are identical except for an additional elongated hole in the later gasket.

►*1955 CLOSED & FORCED THROTTLE VALVE SPRING RETAINER PRODUCTION CHANGE (To prevent retainer breakage):* Spring retainers were increased in size from .134" to .148" beginning with Transmission Serial No. C-128-N. The larger retainers can be installed in valve bodies prior to the above serial number by drilling out the retainer hole with a 5/32" drill. Both retainers can be checked for being in proper position by removing the right hand side cover. *See "Trouble Shooting" for conditions resulting from broken valve spring retainers.*

POWERGLIDE TRANSMISSION SECTIONAL VIEW

►*1955 TRANSMISSION PLANET REVERSE RING GEAR & DRUM ASSEMBLY PRODUCTION CHANGE (To accomodate a new .020" steel thrust washer):* Beginning in production with Trans. Serial No. C-128-D, a new steel thrust washer is being used between planet carrier and reverse gear and drum to prevent galling of thrust surfaces. A Service Package, Part No. 3721564, consisting of a Planet Reverse Ring & Drum Assembly, Part No. 3720472, and an Output Shaft Thrust Washer, Part No. 3720474, is available for service replacement on early cars. *NOTE - This package can also be used on 1953-54 transmissions.*

►*1955 GOVERNOR PRESSURE TEST PLUG CHANGE:* Test plug on side of transmission has been eliminated in production on later cars.

►*1955 AIR CONDITIONED CAR TRANSMISSION FLUID LEVEL & FILLING NOTE:* A filler plug has been added to transmission side cover for use in checking fluid level and adding fluid to transmission.

►*1955 6 CYL. POWERGLIDE LINKAGE ADJUSTMENT CHANGE:* On later cars the part throttle upshift has been lowered to 12-18 MPH by changing the angle of transmission throttle control outer lever and shortening the throttle valve control rod. *See "Throttl Linkag Adjustment" on Car Model pages.*

►*TRANSMISSION OUTER LEVER POSITIONING GAUGE J-5906 REWORK FOR USE WITH 6 CYL. & V8 MODELS:* Remove bolt hole locating pin (larger pin) from gauge, pressing pin from back of lever leg to remove. Cut 5/16" from pin and replace pin in lever leg, pressing it into place to allow apex of pin to project ¾" above lever leg surface. Stake pin in place securely. Separate lever legs and place a 3/16" spacer between legs, then reassemble. In some cases it may be necessary to grind a beveled radius on outer end of bolt lever leg as required.

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinued)

DESCRIPTION

Powerglide transmission is a 2-speed (forward) automatic type consisting of a torque converter and a planetary transmission unit providing automatic operation in "D" (Drive) range. Car starts in 1st speed and upshifts to 2nd, with selector lever in "D" (Drive). Low, Reverse, Neutral, and Park ranges are manually controlled.

OPERATION

Starting in Drive Range—With the selector lever in Drive "D" position, the manual valve is positioned to direct oil pressure to apply side of the Low Servo and to the Low Drive Valve Body so that the car starts out in low range (torque converter plus planetary gear) providing an equivalent gear reduction of 2.2-1 (torque converter) plus 1.82-1 (gears). Depressing the accelerator pedal applies throttle valve pressure behind the shifter valve in the low drive valve body which assists the spring in keeping the shifter valve closed and the transmission in low range. As soon as the car begins to move, the rear pump begins to operate and to supply oil pressure to the governor which controls the upshift as follows:

Normal Upshift—When the rear pump pressure balances the force of the centrifugal weights in the governor, the governor valve directs oil pressure to the Shifter Valve in the low drive valve body and moves the valve to the drive position. This directs main line pressure to the clutch assembly and to the release side of the low servo piston (balancing of low servo pressures allows spring to release band). Application of the clutch and release of the band places the transmission in Drive Range (converter drops out independently when reversal of pressure on stator vanes causes stator to "free-wheel" so that torque converter acts merely as a fluid coupling). Upshift can be delayed by greater throttle opening as follows:

Delayed Upshift—The shift from Low to Drive Range is dependent on the extent to which the accelerator pedal is depressed and will occur at a higher car speed with greater throttle opening. In addition, if the accelerator pedal is depressed beyond the "detent point" (this point reached just before throttle is wide open and will be noted as a definite resistance to further movement of the accelerator pedal), this movement of the pedal compresses the detent spring in the low drive valve body and moves the Detent Valve which then directs throttle valve pressure to the large plunger which assists in holding the shifter valve in the low range position (see Forced Downshift operation below). This delays the upshift to drive range until the car speed reaches 42 MPH. when the governor pressure becomes great enough to move the shifter valve to the high position regardless of the accelerator pedal position (governor pressure increases with car speed until it equals main line pressure).

Normal Downshift—With closed throttle, transmission remains in drive range until car speed drops to approximately 9 MPH. and shifts down to low range at this point. However, transmission can be downshifted at will at higher car speeds to provide greater torque for rapid acceleration as follows:

Forced Downshift—At car speeds below 37 MPH., the transmission can be downshifted from drive to low range for rapid acceleration by depressing the accelerator pedal. The amount of pedal movement required, and the resulting action of the transmission control depends on car speed.

LUBRICATION

Check oil level at 1000 mile intervals, drain and refill transmission at 25,000 mile intervals.

► *CONVERTER DRAIN NOTE:* There is no drain plug on converter unit. Oil trapped in converter need only be replaced when transmission disassembled for overhaul.

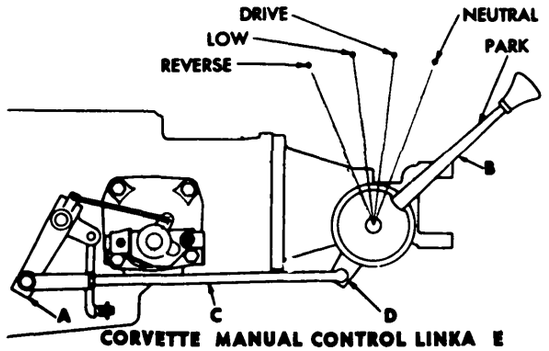
Recommended Oil - Use only Automatic Transmission Fluid Type "A" (as furnished in containers bearing "AQ-ATF" number).

Capacity - Approximately 5 qts. (refill after transmission case drained), 11 qts. (after overhaul with transmission and converter dry).

►**Warming Up Transmission (For Checking or Draining)**—Drive car approximately 5 miles with frequent starts and stops OR warm up transmission in shop as follows: Run engine for 15 minutes at 750 RPM with selector lever in "Dr" position. ***CAUTION*** —Set hand brake tightly to prevent car moving.

Checking Oil Level—Check only with transmission warm and engine idling with selector lever in Neutral "N" position. Remove dipstick from filler tube in engine compartment on right side. Add oil only if level down to "ADD ONE QUART" mark on stick, fill only to "FULL" mark on stick. ***CAUTION—High oil level (above "FULL" mark) will cause foaming and loss of fluid.***

Draining & Refilling—Transmission must be warm. Remove drain plug in rear face of transmission housing under the case to drain the transmission. ***NOTE***—It is not necessary to drain converter. Replace and tighten drain plug. Install 5 qts. of new fluid through filler tube on right side of engine (see Oil Filler Notes above). Idle engine with selector lever in "N" until transmission warm, check fluid level and add additional fluid, as required, to bring level up to "Full" mark on dipstick. ***CAUTION—Do not overfill (will cause foaming).***



Filling (After Overhaul)—Install 3 qts. of fluid through filler tube, start engine and allow it to idle with selector lever in "N", install additional 8 qts. of fluid. Run engine until transmission warm and check fluid level.

LINKAGE ADJUSTMENT

► *THROTTLE LINKAGE ADJUSTMENT NOTE: See CARBURETOR on car model pages.*

Manual Control Linkage: 1954 Models - With selector lever in "R" (Reverse) position, clearance between reverse stop on control shaft lower support and lower lever should be .090". To adjust, loosen control rod swivel, making certain that manual control lever on left side of transmission case is in "R" (Reverse) position, then move selector lever as necessary for correct clearance. Tighten control rod swivel. *NOTE - Short connector rod (bellcrank-to-parking lock lever) on transmission must be correctly installed with arrow pointing up.*

1955-57 Models - Loosen shifter tube lever clamp nut sufficiently to allow upper control rod to move freely in swivel. Push control rod bellcrank (on left side of transmission case) toward front of car as far as it will go, placing transmission in "P" (Park) position. With both control rod bellcrank and selector lever held in "P" (Park) position, tighten shifter lever tube clamp nut securely.

CORVETTE MANUAL CONTROL LINKA E

1954-57 Corvette - Set control rod bellcrank "A" on transmission to reverse position (extreme rearward position). Place transmission selector lever "B" in reverse position (extreme forward position). Adjust rod "C" connecting lower end of selector lever with control rod bellcrank so that rod will enter hole in lower end of selector lever "D" freely.

Neutral Safety Switch (1954-56): Located on bracket on lower end of lower support assembly on steering column. To adjust, loosen two switch assembly mounting screws. Place selector lever in "N" (Neutral), making sure that switch clip is over flats on end of shifter shaft. Insert locating pin through holes in switch mounting bracket and locating plate. Tighten switch mounting screws and remove locating pin.

Neutral Safety Switch (1957): Mounted on steering column mast jacket back of instrument panel. To adjust, loosen mounting screws and place selector lever in "N" (Neutral). Install cotter pins in both holes on switch (each side of pointer) and rotate switch so that pointer is between holes. Tighten screws securely. *NOTE - Slot in switch must be set on center line of tang on shifter tube.* If starter will not operate with selector lever in "N" (Neutral), rotate switch as necessary, *Check to make sure starter will operate only with selector lever in "N" or "P" positions.*

BAND ADJUSTMENT

► *BAND ADJUSTING NOTE: Band adjustment not ordinarily required in service (bands adjusted when reass mbling transmission). Reverse band adjustment r quires removal of Servo Cover Assembly (see Disass mbly data).*

Low Servo Band - Adjusting screw located on left side of transmission case (under cover). To adjust band, remove adjusting screw cover. Use Tool J-4277 (see "Tool Modification Note" below), loosen adjusting screw locknut and tighten low band adjusting screw to 5-7 ft. lbs. *(NOTE - This procedure is new and supersedes th previous instructions which required that the scr w b tighten d firmly).* Back screw out four complete turns, and tighten locknut, taking care not to allow screw to turn. Replace adjusting cover.

C NTINUED ON NEXT PAGE

POWERGLIDE (C ntinued)

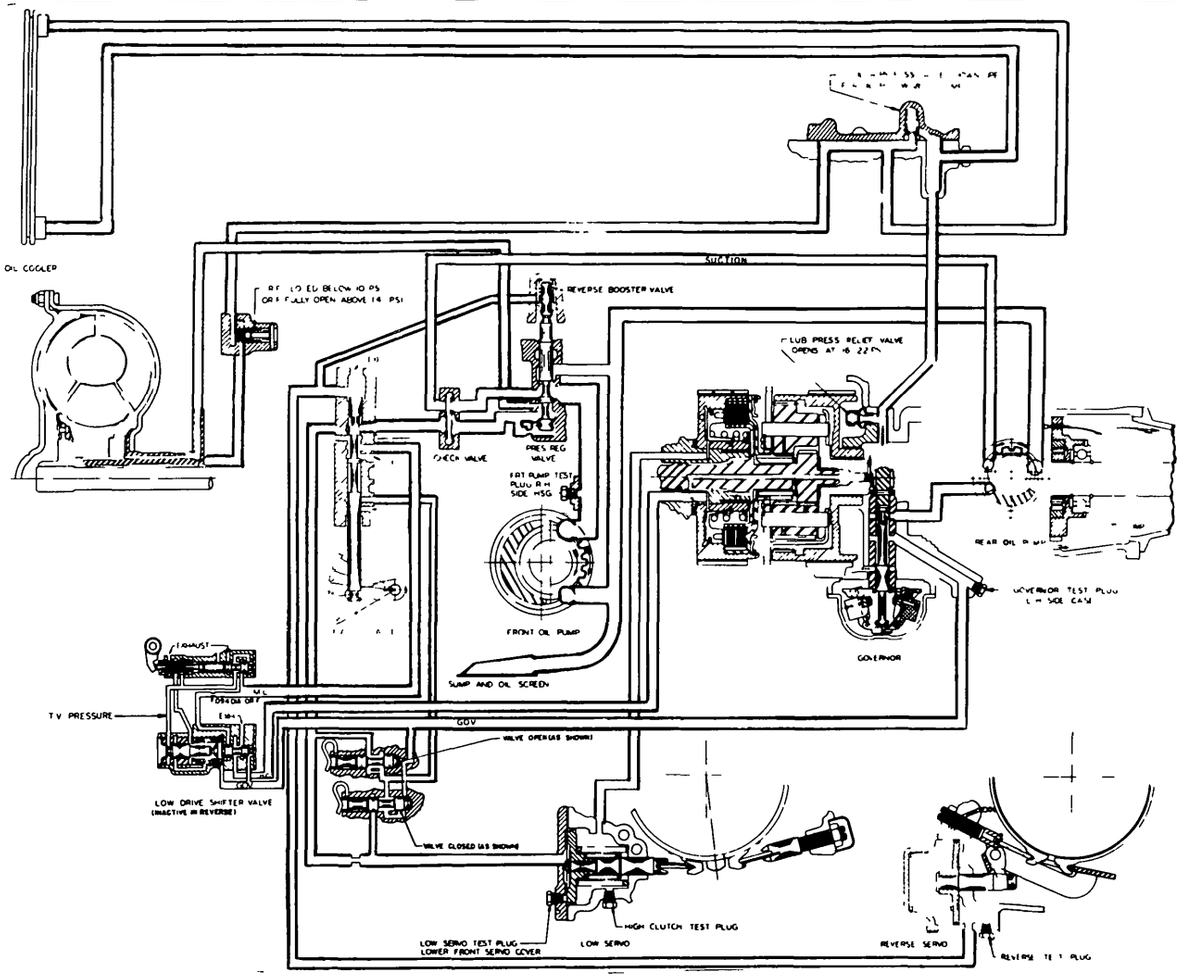
►**Tool J-4277 Modification (for Low Servo Band Adjustment)**—Adjusting screw has recessed head for ¼" Allen wrench. To use tool, remove screwdriver retainer and special screwdriver from tool, use ¼" Allen Wrench in place of the screwdriver in the tool.

Reverse Servo Band: 1954 Models - Adjusting screw located on right side of case **under servo cover.** With servo cover removed, install Tool J-4277 on adjusting screw and loosen locknut. Turn adjusting screw in slowly **and at same time** check endplay in linkage by pushing and pulling on servo return spring directly below adjusting screw. Continue to turn screw in until endplay is **just taken up.** *NOTE - At this point band must be free on drum so that drum can be rotated easily by hand.* Back off adjusting screw 1/8-1/4 turn, then tighten locknut being careful not to allow adjusting screw to turn. *CAUTION - Reverse band adjustment is very sensitive and must be done carefully.*

1955-57 Models - Adjusting screw located on right side of transmission **under servo cover.** With servo cover removed, install Tool J-4277 on adjusting screw, then loosen locknut. Rotate reverse drum to center it in reverse band, then tighten adjusting screw until all endplay between linkage and band is removed without compressing band. *NOTE - Reverse drum must be free to rotate after this adjustment.* If reverse drum is not free to rotate after adjustment, back off adjusting screw ¼ turn at a time until drum is free to rotate.

TROUBLE SHOOTING

SEVERE CLOSED THROTTLE DOWNSHIFT "CLUNK": May be caused by a broken closed throttle cushion valve spring retainer. Check this condition by removing right hand side cover and inspecting retainer. *See "Closed & Forced Throttle Valve Spring Retainer Production Change" above.*



MOMENTARY RUN AWAY IN LOW UP TO 30 MPH (WIDE OPEN THROTTLE ACCELERATION): May be caused by a broken forced throttle cushion valve spring retainer. Check mainline pressure which will be lower just prior to shift, and the stall pressure will be low if the faulty transmission operation is caused by a broken retainer. *See "Closed & Forced Throttle Valve Spring Retainer Production Change" above.*

EXCESSIVE SLIPPAGE (High engine speed in relation to car speed, poor acceleration, or engine runs away on turns).

1) In all Speed Ranges—Low oil level. Incorrect control linkage adjustment. Air leak in oil pump suction pipe. Low front oil pump pressure.

2) In Drive Range—Incorrect control linkage adjustment. Damaged or leaking clutch piston seal (worn or burned clutch plates resulting from partially engaged clutch).

3) In Low Range—Incorrect control linkage adjustment. Low Band out of adjustment. Sticking accumulator valve, modulator lever, or modulator valve. Damaged or worn Low Servo Piston Ring resulting in poor band application or excessive oil leakage into clutch apply circuit causing partial clutch application and possibly burned clutch plates (check by connecting pressure gauges to Low Servo Apply and to High Clutch test points—there should be no pressure indicated at High Clutch point with selector lever in "L").

1955-57 POWERGLIDE TRANSMISSION HYDRAULIC CIRCUITS

CAR CREEPS (Forward or Backward).

1) With Control Lever in Neutral—Incorrect control linkage adjustment. Clutch piston vent valve stuck closed. Clutch plates sticking or incorrectly assembled (not "stacked" in correct order).

2) Creeps forward with Control Lever in Reverse or backward with Lever in Low—Incorrect control linkage adjustment.

CAR WILL NOT MOVE (Rear wheels may be locked or free).

1) With Control Lever in any range (rear wheels free). If this occurs at other times than after reversing car, see causes listed under **EXCESSIVE SLIPPAGE** above. If this occurs only after reversing car (indicating loss of front pump pressure) check: Rear pump air leakage into front pump suction line (causing front pump to lose its prime). Rear pump gasket leakage. Front pump clearance excessive.

2) With Control Lever in any range (rear wheels locked). Parking pawl lock engaged. Broken parts in transmission. Parking brake applied.

3) With Control Lever in Drive Range (rear wheels free). If engine runs away and transmission is hot, check for: Low radiator water level, clogged oil cooler, sticking thermostatic valve, or dragging Low Range Band (causing over-expansion of clutch parts due to excessive heat).

SHIFTS ARE ROUGH.

1) Low-to-Drive Shift (car in motion). Incorrect Low Band adjustment. Clutch plates worn or binding. Modulator control lever or piston sticking (will cause excessive pressures). Accumulator dump valve orifice plugged.

If engine speeds up during this shift—Check for incorrect low band adjustment and worn or binding clutch plates.

2) Drive-to-Low Shift. Incorrect Low Band adjustment. Accumulator piston stuck closed. Modulator control lever or piston stuck (will cause excessive pressure).

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

3) **Neutral-to-Reverse.** Incorrect reverse band adjustment. Accumulator piston stuck closed. Modulator control lever or piston stuck (will cause excessive pressure).

CHATTERS WHEN STARTING.

1) **In Low Range.** Incorrect Low Band adjustment. Worn or rough band, scored drum. Clutch not disengaging properly due to distorted or binding plates, sticking clutch piston, sticking piston vent valve, or damaged or worn Low Servo Piston Ring allowing oil leakage into clutch apply circuit and causing partial clutch application (see tests for Excessive Slippage in Low Range above).

2) **In Drive Range.** Incorrect Low Band or Reverse Band Adjustment. Bands worn or rough, drums scored.

3) **In Reverse Range.** Incorrect Reverse Band adjustment. Worn or rough band, scored drum. Reverse ring gear and drum bushing worn or damaged.

REVERSE OPERATION JERKY OR DRAGGING.

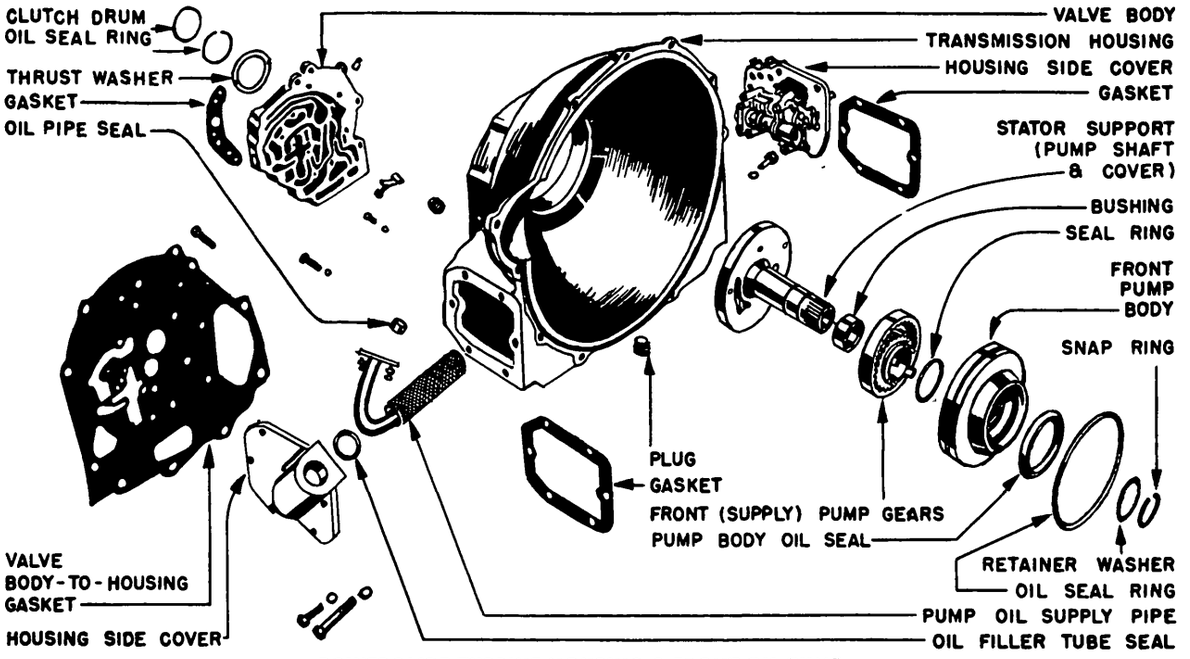
1) Clutch plates are incorrectly assembled (not "stacked" properly) or sticking. Clutch piston vent valve stuck closed.

REVERSE CAN NOT BE ENGAGED WITH ENGINE RUNNING: If reverse can only be engaged when engine not running, check for accumulator snap ring being out of place (allowing accumulator valve and body to be forced against clamp nut on parking lock lever shaft and apply spring assembly, blocking shift into reverse). *NOTE*—Above condition will not prevent shift into Low Range).

DRIVE-TO-LOW r LOW-TO-DRIVE SHIFT DIFFICULT: May be caused by improperly drilled high clutch feed orifice in valve body resulting in slow clutch application in Drive Range and slow clutch release when shifting from Drive to Low (restricted orifice will cause slow oil flow). Check by connecting pressure gauges to Low Servo Apply and to High Clutch (low servo release side) and noting pressures as follows:

1) Move selector from Neutral to Drive with engine idling. If pressure builds up much more rapidly on Low Servo Apply gauge than on High Clutch gauge, a restriction in the passage (undersized orifice) is indicated.

2) Move selector from Drive to Low. Pressure in High Clutch gauge drops slowly, oil drainage from clutch is restricted. NOTE—This will result in slow Low Band application and clutch drag (may cause burned clutch plates).



HIGH CLUTCH PLATES BURNED OR CLUTCH FAIL

►***CAUTION—When High Clutch failure noted, following tests should be mad before transmission removed, and transmission should also be carefully examined after removal and disassembly.***

1) Connect pressure gauges to Low Servo Apply, High Clutch (low servo release side), and to Reverse Servo points. Operate engine to supply oil pressure.

2) Place selector lever in Drive position and note pressure build-up in High Clutch gauge. Slow build-up indicates restriction in high clutch apply orifice resulting in clutch slippage and burned plates.

3) Place selector lever in Low position. High Clutch gauge should not show any pressure. Pressure at this point indicates leakage past Low Servo Piston Ring resulting in partial clutch application and burned clutch plates.

POWERGLIDE TURBINE HOUSING & FRONT OIL PUMP

4) **Place selector lever in Reverse position. High Clutch gauge should not show any pressure. Pressure at this point indicates leakage between the converter "out" and low servo "release" channels in valve body or damaged Housing-to-Valve Body gasket. This condition will cause partial clutch application and burned clutch plates.**

NOISE IN TRANSMISSION.

1) **Buzzing Noise (All Ranges).** Low oil level. Pump gear interference with crescent in pump. Pump check valve not seating.

2) **Ringing Noise in Converter.** Low oil level. Air leak in pump suction line (pump not seated properly) resulting in low oil level in converter. Pressure regulator valve stuck (closing converter inlet port). Leakage in oil line between front pump and regulator valve.

3) **Clicking Noise.** Incorrect manual linkage adjustment (causing interference between parking lock pawl and gear).

4) **Whining Noise.** Transmission gear teeth worn. Pump gear clearance excessive or pump gear bushings worn.

FUEL CONSUMPTION EXCESSIVE.

1) **Transmission Causes.** Converter stator freewheeling cams and roller incorrectly assembled. Clutch piston vent valve stuck open.

TRANSMISSION OIL BEING FORCED OUT OF FILLER PIPE: Caused by aeration and foaming of the oil due to one or more of the following:

NOTE—This condition may also cause Loss of Power and Lower Stall Speed (due to converter turbulence and lower pressures in control circuits).

1) Oil level too high allowing planet carrier to revolve in oil and aerate it. Correct by lowering oil level to correct point (see **LUBRICATION**) and driving car for 5 miles to work out air bubbles.

2) Oil suction pipe split, seal damaged, bore for suction pipe in housing too deep, or suction pipe retainer ears bent (preventing proper compression of the seal) resulting in air leaks in oil suction line.

3) Sand hole in suction bore of transmission case or housing or in suction cavity in valve body resulting in air leaks in oil suction line.

TESTING

►***TESTING CAUTION***—Transmission oil level must be checked and corrected (see **LUBRICATION**) and ***transmission must be warmed up before tests made.***

Warming Up Transmission: Transmission must be warmed up by road driving or in the shop exactly as follows before checking for oil leaks or trouble.

Road Warm-Up—Drive car for approximately 5 miles with frequent starts and stops to approximate heavy-traffic conditions.

Shop Warm-Up—Set hand brake tight to hold car, place selector lever in "D" range, start engine and run for 15 minutes at 750 RPM. At end of 15 minutes, transmission will be warmed up sufficiently for testing regardless of initial temperature.

►***CAUTION—Recheck oil level after warm-up and before making following tests.***

ROAD TEST: Road test car when endeavoring to determine the reasons for the following difficulties:

Clutch Slippage: Connect gauges to the test points of the low servo apply and high clutch (release side of low servo). Position selector lever in "D" range and when car starts to move on acceleration, carefully check the pressure readings. Before the upshift takes place, the gauge connected to the low

CONTINUED N NEXT PAGE

POWERGLIDE (C ntinu d)

servo apply test point should record between 85 and 95 lbs. After a normal upshift takes place and the high clutch has time to become fully engaged, both gauges should record 85-95 lbs. If on this type of shift, the gauge on the high clutch (release side of low servo) test point records 85-95 lbs., and the clutch slips or does not fully engage, it indicates a mechanical fault in the clutch. If the gauges do not record between 50-60 lbs. with engine idling at 425 RPM, or from 85 to 95 lbs. upon acceleration, the following items will require checking as it indicates leakage in the oil circuits. (a) Pressure regulator valve stuck, (b) Leak at low servo piston ring (between bore and ring), (c) Leak at low servo piston rod (between bore and rod), (d) Leak at valve body to case gasket, (e) Leak between valve body and housing, (f) Front pump clearances not correct, (g) Leak at low drive valve body (check gaskets and shifter valve), (h) Check passages in transmission housing for porosity, (i) Loose suction screen connection.

Closed Throttle Downshift "Clunk": High engine idle speed, or Closed Throttle Downshift Cushion Valve stuck.

Harsh Abrupt Upshift Above 25 MPH: Forced downshift cushion valve stuck closed.

Improper Upshifts and Downshifts: Refer to "Shift Patterns" below. Connect gauges to throttle valve and governor test points *(NOTE—See "Governor Pressure Test Plug Production Change" above).* Throttle valve pressure ranges from 0 to 62 lbs., depending to what extent the accelerator is depressed. Governor pressure is governed by road speed. If difficulty is experienced with the "Shift Patterns" it is recommended that the governor pressure be checked first to determine whether the pressure is within proper range, for if not, it will effect the "Shift Patterns" and the governor assembly is the first thing that should receive attention. Throttle valve pressure is another thing that effects "Shift Patterns" and if governor pressure is correct it is indicative that trouble is in the low drive valve body provided the positive linkage and throttle valve linkage is in proper adjustment.

►*STALL TEST NOTE: Stall testing of transmission is not r comm nded.*

PRESSURE TESTS: Connect pressure gauges at the following points and make the tests listed below.

►*TEST GAUGE NOTE:* Five gauges are required. The four-gauge panel, No. J-4872, can be modified for use by installing an additional gauge furnished in conversion package No. J-5491 (reverse original gauges on panel, drilling additional hole to mount new gauge on lower edge of panel).

Gauge Connections—Connect gauge at each of the following points:

1) **Low Servo Apply Pressure**—Plug on lower front of servo cover on right side of transmission. *CAUTION—Do not confuse this plug with Modulator Pivot Pin Retaining Plug which is slightly to rear of this Low Servo Apply Plug.*

2) **Clutch Apply Pressure (Low Servo Release)**—On bottom of transmission case at center and adjacent to servo mounting flange.

3) **Reverse Servo Apply Pressure**—On bottom of transmission case at rear and adjacent to servo mounting flange.

4) **Throttle Valve Pressure**—At hex-head plug in center of Low and Drive Valve Body Cover on left side of converter housing.

►*GOVERNOR PRESSURE TEST PLUG PRODUCTION CHANGE: Test plug on side of left hand side cover has been eliminated beginning in production with Trans. Serial No. C-428-D. Earlier model side covers will retain this plug.*

5) **Governor Pressure**—At plug on side or at upper end of channel in Low and Drive Valve Body Cover on left side of converter housing (upper plug is between second and third top cover screws (counting from top front corner of cover).

6) **Main Line Pressure**—At plug on upper end of channel in Low and Drive Valve Body Cover on left side of converter housing (plug is between third and fourth top cover screws (counting from top front corner of cover).

7) **Clutch Apply or Main Line Pressure**—At plug at outer end of channel in Low and Drive Valve Body Cover on left side of converter housing (this plug is at lower rear corner of cover).

Test Pressures—*CAUTION—Representative pressures listed below may vary 5% (higher or lower).*

1954 MODELS

LOW RANGE (MANUAL)

Idling at 450 RPM.

Pressure Point	Pressure
Main Line (Frt. Pump)	140 lbs.

At 30 MPH.

Pressure Point	Part Throttle (Road Load)	Full Throttle (Thru Detent)
Low Apply	160 lbs.	190 lbs.
Governor①	60 lbs.	60 lbs.

DRIVE RANGE (AUTOMATIC)

Transmission in Low Range

Pressure Point	Light Throttle (10 MPH.)	Thru Detent (30 MPH.)
Low Apply	70 lbs.	115 lbs.
Clutch Apply	0	0
Governor①	10 lbs.	60 lbs.
Throttle Valve	0-5 lbs.	45 lbs.

Transmission in High Range

Pressure Point	Light Throttle (30 MPH.)	To Detent (40 MPH.)
Low Apply	55 lbs.	120 lbs.
Clutch Apply	55 lbs.	120 lbs.
Governor①	60 lbs.	75 lbs.
Throttle Valve	45 lbs.	58 lbs.

①—To check governor pressure only, vacuum line to modulator must be disconnected.

1955-57 MODELS

FRONT PUMP PRESSURE

	Pressure
Idle (425 RPM)	50-60 lbs
Above Idle	85-95 lbs.
Reverse (Idle 425 RPM)	50-60 lbs.
Reverse (Above Idle)	165-195 lbs.

DRIVE (AUTOMATIC)

Transmission in Low Range

	Light Throttle (10 MPH)	Through Detent (45 MPH)
Low Apply	85-95 lbs.	85-95 lbs.
Clutch Apply	0 lbs.	0 lbs.
Governor	8-13 lbs.	72½-76½ lbs.
Throttle Valve	①	①

Transmission in High Range

	Light Throttl (30 MPH)	To Detent (45 MPH)
Low Apply	85-95 lbs.	85-95 lbs.
Clutch Apply	85-95 lbs.	85-95 lbs.
Governor	52-56 lbs.	72½-76½ lbs.
Throttle Valve	①	①

①—Throttle valve pressure will vary from 0 to 62 lbs., depending on throttle position. At wide open throttle (through detent) pressure should read 61 to 63 lbs., on acceleration.

REMOVAL FROM CAR (EXCEPT CORVETTE)

Transmission & Torque Converter are removed as an assembly. *CAUTION—Torque converter is not retained in housing as on previous transmission and special holding tool must be used to prevent converter falling out when transmission assembly removed.*

1954 MODELS

CHEVROLET TRANSMISSION ASSY. REMOVAL:

1) Raise car and support securely on jack stands. Remove floor mat and toe pan plate.

2) Take out three top turbine housing attaching bolts (through toe pan hole).

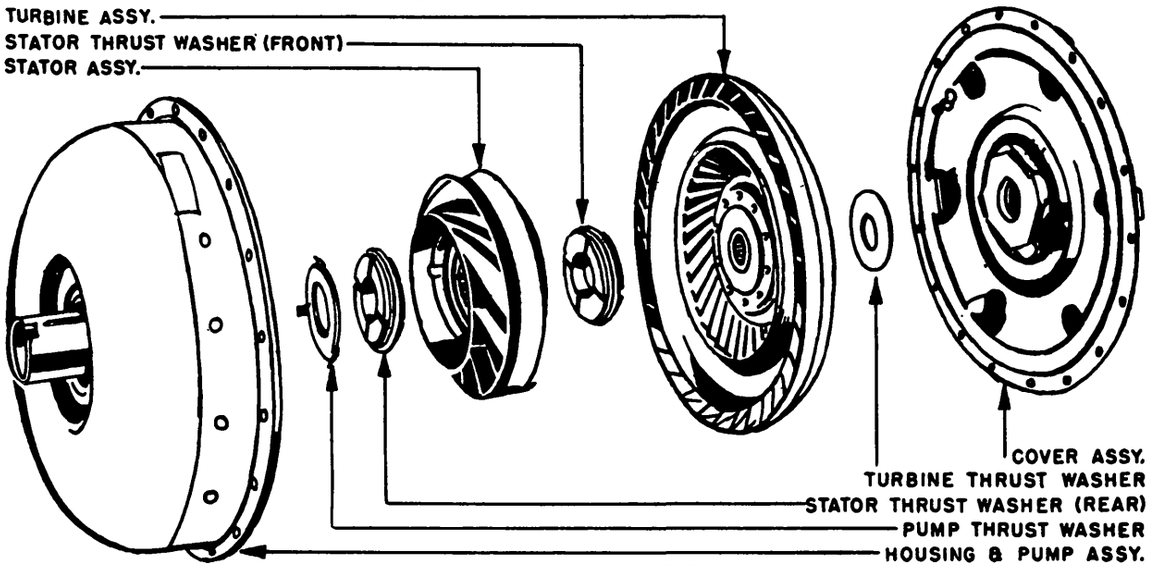
3) Disconnect speedometer cable at transmission and hand brake rod from cross-shaft. Drop cross-shaft, brake cables, and spring.

4) Free universal joint collar by taking out cap screws on back of transmission case, slide ball and collar back on shaft. Support propeller shaft with jack, take out front universal trunnion bearing cap screws, split universal, lower front end of propeller shaft.

5) Take out two upper right transmission-to-converter housing bolts. Use Adapter No. J-5214 and Adapter Plate No. J-5526 mounted on a standard hydraulic floor jack to support transmission weight.

C NTINUED N NEXT PA E

POWERGLIDE (Continu d)



6) Drain transmission case (see Lubrication). Disconnect transmission oil cooler lines and vacuum line.
7) Take out two lower turbine housing attaching bolts. Remove flywheel cover and flywheel underpan extension.
8) Remove all spark plugs. Disconnect exhaust pipe at manifold, disconnect muffler support. Tie exhaust pipe and muffler to left frame side member out of the way.
9) Disconnect throttle control rod from control lever on left side of transmission case. Disconnect both long and short selector control rods from levers on left side of transmission, tie throttle control rod and long selector rod up out of the way. Remove bell crank lever and stud from transmission case.
10) Remove all six flywheel-to-converter bolts working through housing opening on left side (use tool J-4281 to turn engine crankshaft and align each bolt with housing opening for access).
11) Clean all dirt from around filler tube and dipstick fitting on transmission side cover, remove housing bolt holding filler tube, remove filler tube and dip stick.

►***CAUTION—Cover the filler tube opening with masking tape or plug with rubber stopper to keep out dirt.***

12) Support engine with a jack under the oil pan. Remove transmission-to-rear support bolts, remove the transmission support and cross-member.
13) Take out all remaining turbine housing bolts (lift or lower engine for access to bolts).
14) Move transmission straight back to clear flywheel pilot from flywheel. Install converter assembly holding tool J-5384 (attach tool with one converter turbine housing bolt). ***NOTE—this tool will prevent converter assembly falling out while transmission being removed.***

1955-57 MODELS

TRANSMISSION ASSEMBLY REMOVAL: (1) Raise car and install jack stands front and rear. Turn back floor mat and remove toe pan plate.
2) Remove spark plug wires on all models. Disconnect ground strap from battery and wires from starting motor solenoid on eight cyl. models only. Disconnect oil cooler lines retaining clip bolt from right side cover and disengage lines from retaining clip on engine. Move lines away from transmission and tie to right frame side rail.
3) Disconnect throttle valve control rod from throttle valve control outer lever and manual shift control rod (long rod) from bellcrank. Split rear universal joint. Then remove propeller shaft and front universal joint as an assembly by sliding it rearward until front joint is free of transmission output shaft.
4) Remove drain plug from rear of converter housing and drain transmission. Clean dirt from around filler tube, dipstick and transmission cover and remove side cover bolt retaining filler tube in position. Remove filler tube and dipstick. ***(CAUTION—Use masking tape or rubber stopper to cover filler tube opening.***
5) On V8 cars only, remove starter, and disconnect exhaust pipe from crossover pipe. On 6 Cyl. cars disconnect exhaust pipe from exhaust manifold.
6) Disconnect muffler from muffler support bracket and move the exhaust pipe and bracket as an assembly to the left and tie it to left frame side member.

POWERGLIDE TORQUE CONVERTER

7) Remove flywheel inspection hole cover and remove the three flywheel to converter attaching bolts through the opening that is adjacent to the starting motor, (opening on six cylinder cars is on left side of engine).
8) Remove all converter housing to flywheel housing attaching bolts except the top three. Install engine support bar or cradle to support engine. Position jack under transmission (using a suitable transmission handling device). Remove both rear engine mountings making sure that engine is properly supported before removing mountings.
9) Remove the three upper converter housing to flywheel housing attaching bolts through opening in toe pan. Move transmission to rear slightly and install converter holding tool J-5384. Lower transmission on jack and remove from under car.

DISASSEMBLY—TRANSMISSION

►**DISASSEMBLY & REASSEMBLY CAUTION:** ***CLEANLINESS IS EXTREMELY IMPORTANT when opening up transmission. Thoroughly CLEAN exterior of case first, CLEAN each part as removed with cleaning solvent or gasoline and dry with air—do not use wiping cloths which will leave lint on parts. Store all parts in clean storage bins.***

DISASSEMBLY OF TRANSMISSION (Into Major Units): 1) Place transmission on bench (use holding fixture J-3361) and remove all units as indicated below.
2) Remove converter assembly holding tool J-5384 from housing, remove converter assembly by pulling it straight out of housing.
3) Take out right side cover attaching bolts, remove side cover, gasket, and oil pump suction screen.
4) Take out Low & Drive Valve Body attaching screws on left side of transmission, remove valve drive body assembly and gasket. CAUTION—Do not remove outer lever assembly from valve body (this retains inner lever assembly in body).
5) Loosen all servo cover bolts slightly and break servo cover loose if it sticks to case (reverse servo spring and pressure regulator spring bear against cover) **using care not to allow cover to tip** which may damage or break tip of pressure regulator valve. Use guide bolts to maintain cover alignment or turn all cover bolts out evenly while exerting pressure on cover, then lift cover and gasket straight off until cover clears tip of pressure regulator valve. Remove reverse servo spring and pressure regulator springs, lift regulator valve out.

►***CAUTION—Handle valve carefully to prevent damag and store it by itself to avoid nicking or scratching of the polished surfaces.***

6) Remove low band adjusting screw cover, loosen low band adjusting screw locknut using tool J-4277 (see Tool Modification below), and tighten low band adjusting screw to hold clutch assembly in place.

►***CAUTION—Make sure low piston assembly does not fall out of bore and become damaged.***

►**Tool J-4277 Modification Note**—Low band adjusting screw has recessed head for Allen wrench. To use tool, remove screwdriver retainer and special screwdriver from tool, use ¼" Allen wrench in place of screwdriver in tool.

7) Working from inside of converter housing, remove the converter housing-to-transmission case self locking bolt. Remove the converter housing-to-transmission bolts and lockwashers and install two ⅜"—16 x 3¾" guide pins (part of Pilot Stud Set J-3387). Shift transmission into Reverse and then carefully separate transmission from converter housing. Remove valve body to transmission case gasket.

8) Remove manual valve from valve body on rear of converter housing, remove manual valve lever from housing, remove bronze thrustwasher from valve body oil delivery sleeve.

C NTINUED N NEXT PAGE

POWERGLIDE (C ntinu d)

►***CAUTION—Handle manual valve carefully to prevent damage and store it by itself to avoid nicking or scratching of the polished surfaces.***

9) Take out all bolts and lockwashers attaching valve body to converter housing and front pump to valve body. Remove valve body and gasket.

►***CAUTION—Handle valve body and valves carefully to protect them from damage.***

10) Use Front Pump Driver Tool J-4263-5 to remove pump assembly from converter housing.

11) Loosen low servo band adjusting screw to free clutch assembly, remove input shaft, clutch assembly, and low sun gear thrustwasher from transmission case.

12) Remove low servo band, strut assembly, low servo piston and piston return spring from transmission case.

13) Remove speedometer driven gear assembly. Take out universal joint retainer bolt and lockwasher on rear end of output shaft, slide universal joint yoke off end of shaft.

14) Take out attaching bolts and remove governor cover on left side of transmission case, remove gasket. Remove governor assembly (allow governor to turn in clockwise direction while withdrawing it from case).

15) Use tool J-3383 to rotate parking lock pawl spring until end unhooked from case, remove spring and parking lock pawl. Remove parking lock lever and steel washer, parking lock lever shaft assembly, and oil seal from case.

16) On 1954 models, install Tool J-938 on rear face of transmission case and engage end of output shaft. Turn tool handle to force output shaft forward out of rear bearing. Remove tool, then remove planet carrier and output shaft through front of case.

17) On 1955 & later models, remove transmission oil seal using Tool J-5859, then remove transmission extension assembly and "O" ring seal. Remove speedometer drive gear from output shaft with Tool J-5814. *CAUTION - Do not attempt to remove planet carrier until transmission rear bearing locating snap rings, retainer and bearing are removed.* Remove rear bearing retainer and rear bearing locating snap ring from output shaft. Remove rear bearing from output shaft with Tool J-5814, then remove rear bearing front snap ring. Working from front of transmission, position arrow on face of external gear of planet carrier assembly at top center (this aligns drive pin in output shaft with "eyebrow" opening in rear oil pump cover). Planet carrier assembly can now be removed through front of case. *CAUTION - Do not lose rear oil pump drive pin.*

18) On all models, remove reverse drum and thrust washer. Using Tool J-4277, loosen reverse servo adjusting screw locknut, then back off screw and remove reverse brake band assembly and reverse servo piston. Remove rear pump attaching bolts and lockwashers and remove rear pump assembly and gasket. Remove lubricating pressure relief valve from case.

NOTE - For DISASSEMBLY of above units, see OVERHAUL data following.

VERHAUL

►*LOW BAND ANCHOR STRUT INSTALLATION CAUTION:* The guide stamping of the anchor strut assembly must be installed **toward** the band.

►*1957 POWERGLIDE LOW SUN GEAR THRUST WASHER PRODUCTION CHANGE:* The "roller type" thrust washer (078" thick) used in production at this location has been changed to a bronze thrust washer (095" thick). When servicing all 1957 Powerglide clutch assemblies installed in 1953-1957 cars where either the low sun gear thrust washer ("roller type or bronze type"), or the clutch drum thrust washer requires replacement it will be necessary to replace the washer at both of these locations. The service replacement clutch drum thrust washer (untanged) Part No. 3745897 is .061" thick. Replacement low sun gear thrust washers are furnished in the following thicknesses for selective fitting: Part No. 3719296 (095"); 3719297 (.120"); 3719298 (.145"). *See "Transmission Endplay Check & Adjustment Change" below.*

►*1957 POWERGLIDE TRANSMISSION ENDPLAY CHECK & ADJUSTMENT CHANGE:* The procedure for selecting and installing the service thrust washers in all transmissions using the 1957 clutch will be the same as for previous (1953 & later) transmissions except that the low sun gear-to-reverse gear clearance will be .025-.050". *See "1957 Powerglide Low Sun Gear Thrust Washer Production Change" above for correct thrust washers to use.*

►**"O" RING SEAL CAUTION:** ***These seals must be discarded when removed and a new seal installed exactly as directed below.*** "O" ring rubber seals are special design and are installed with side clearance in ring groove so that oil pressure on seal deforms the rubber and extrudes a portion of the rubber into the clearance space between the mating parts to provide a positive seal against loss of oil pressure. Seals **must not be re-used.**

"O" Ring Seal Installation—Make certain that parts are clean and that burrs and sharp edges are removed. Seal must be free of any twists (place ring on flat surface and allow it to assume natural position) and **must not be twisted during installation.** Engage one side of ring in groove, pull other side straight back until it can be fitted in groove without twisting. Work ring against trailing edge of groove (last side to enter when parts assembled) using flat tool entered between ring and leading edge of groove to move ring without twisting. Lubricate "O" ring and parts with transmission oil.

CONVERTER OVERHAUL (Unit on bench—after removal from transmission):

Disassembly: 1) Remove all converter cover attaching bolts and locknuts, use small punch to drive out split dowel pin in cover, lift cover off.

2) Remove turbine assembly, stator assembly, stator thrustwashers, and pump thrustwasher. Remove thrustwasher from turbine hub. Remove "O" ring seal from converter cover.

3) Remove stator race from stator assembly, remove snap ring and over-run cam retaining thrustwasher, remove cam rollers, springs, and guides (8 each).

►***CAUTION—Use care when separating parts so that cam rollers, springs, and guides do not fall out and become lost.***

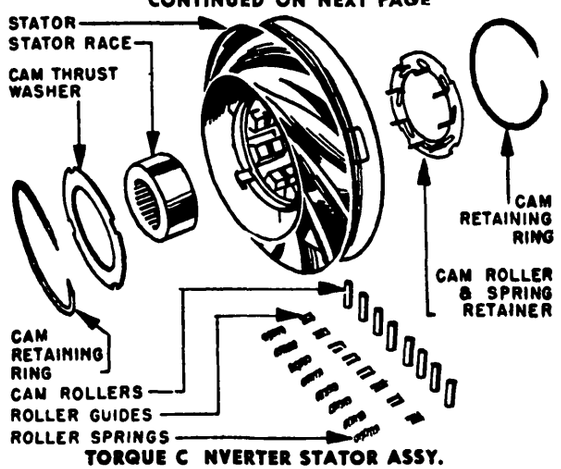
4) Remove snap ring on opposite end of stator and remove over-run cam roller and spring retainer.

►***CAUTION—Use care to prevent damage to over-run cam and see that cam does not become disengaged from stator hub.***

Inspection: Wash all parts in cleaning solvent and dry with air. Inspect converter pump hub, turbine hub, and converter cover bushing for galling, scoring, or excessive wear. Inspect all thrustwashers for galling, scoring, or excessive wear. Check turbine vanes and stator vanes for looseness or damage. Inspect stator race and cam rollers for galling or scoring. Inspect cam springs for distortion. Check spring guides for wear or damage. Inspect over-run cam roller and spring retainer for wear or damage. If bushing in converter cover worn or damaged, install new bushing as follows:

Converter Cover Bushing Replacement: Precision type bushing, No. 3702079, furnished for field installation. Use bushing remover tool J-5381 to remove old bushing from cover. Place new bushing on pilot end of Bushing Replacer Tool J-5382 and press bushing into place in cover using an arbor press. ***NOTE—Bushing is finished to size and does not require reaming.***

Reassembly: 1) Install over-run cam roller and spring retainer in stator with retainer prongs pointing toward **rear** of stator. ***NOTE***—Stator has word "Front" cast in and stator vanes are thicker at front end.



2) Assemble cam rollers, springs, and guides in cam pockets (***CAUTION***—Guides are curved and this curvature must follow curvature of cam). Install over-run cam thrustwasher and retaining snap ring.

3) Coat stator race and loading tool J-5930 with light film of oil, place stator race on pilot end of loading tool and carefully rotate the stator over the tapered end of the loading tool and the stator race (***CAUTION***—rotate stator in clockwise or freewheeling direction and use great care not to dislodge cam rollers). Check operation of stator. Stator should turn freely in clockwise direction viewed from front end.

4) Place converter pump on bench, open end up Install thrustwasher on converter pump hub making certain that tabs are engaged in the hub flange notches. Assemble **both** thrustwashers on stator and install stator assembly on converter pump.

►***CAUTION—Make certain that cut-outs in over-run cam roller and spring retainer are facing upward or toward converter turbine.***

CONTINUED ON NEXT PAGE

TORQUE C NVERTER STATOR ASSY.

POWERGLIDE (C ntinued)

5) Install thrustwasher on turbine hub and assemble turbine on converter pump.
6) Install NEW "O" ring seal on converter cover, align dowel pin holes in cover with dowel pins in converter pump, install cover assembly. Install all cover attaching bolts and lockwashers and tighten evenly to 15-20 ft. lbs.

TRANSMISSION OVERHAUL: *After removal from case, overhaul sub-assemblies or units as follows:*

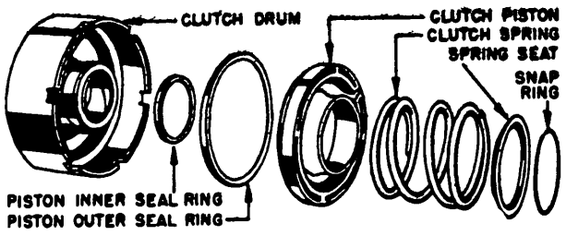
Planetary Unit Clutch: Place unit on bench with clutch flange upward.

Disassembly—1) Remove clutch flange retainer ring, lift out clutch flange retainer. Remove clutch flange assembly from clutch drum. Remove clutch hub thrustwasher, hub, and all clutch plates from clutch drum.

2) Place clutch drum in bench press, install spring compresion tool J-5133 and compress spring enough to remove snap ring, use KMO-410 pliers to remove snap ring. Relieve spring pressure, remove tool, lift out clutch spring seat and spring.

3) Rap clutch drum face down on a wood block to dislodge clutch piston, lift piston out, remove outer seal ring from piston and inner seal ring from clutch drum hub.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect drum brake band surface for scoring or burning, check drum bushing for scoring or excessive wear. See that clutch flange does not have any appreciable play in drum slots. Check all clutch plates for burning or galling, see that composition plates are free fit on clutch hub and that steel plates are free fit in clutch flange. Check low sun gear for nicked or burred teeth. Inspect relief valve steel ball in clutch piston and make certain that ball is free to move in hole and that orifice to rear of piston is open. If necessary, replace ball as follows:



Relief Valve Check Ball Replacement—Remove staking and remove ball. Inspect hole and ball seat and make certain it is free from burrs or nicks, see that new ball seats perfectly. Insert ball and carefully stake around edges of hole so that ball cannot fall out. *CAUTION—Ball must be free to move in hole after staking completed.*

►***REPLACEMENT PARTS CAUTION: See Chevrolet Changes, Cautions, Corrections for clutch production changes and latest type replacement parts.***

Reassembly—1) Install new outer seal ring on clutch piston with lip of seal toward pressure side of piston *(CAUTION—use care not to stretch seal).* Install new inner seal ring on inner hub of clutch drum with lip of seal toward bottom of clutch pocket.

2) Lubricate inner diameter of clutch drum and both seals with transmission oil, carefully install piston in clutch drum using a piece of feeler stock to insure seating of outer seal ring in clutch drum.

3) Install clutch spring and spring seat, use tool J-5133 in an arbor press to compress spring *(CAUTION—Make certain spring does not hang up in snap ring groove which would damage spring seat and groove),* install snap ring. Release pressure, remove tool.

POWERGLIDE CLUTCH PISTON ASSY.

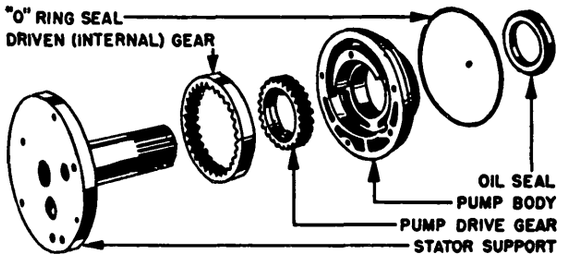
4) Install thrustwasher on clutch hub *(CAUTION—see that four tabs on washer fit into slots in clutch hub),* install clutch hub and thrustwasher on clutch flange with open side up. Install five steel and four composition clutch plates, starting with a steel plate and alternating plates *(NOTE—Steel plates are "waved" and can be installed either side up).* Install clutch drum assembly on clutch flange assembly, then invert entire unit, install clutch flange retainer and flange retainer ring.

5) Check endplay using a feeler gauge inserted between clutch flange drive lug and drive slot in drum. This endplay must not exceed .013". Adjust by installing retainer ring of correct thickness to provide correct endplay. *NOTE*—Retainer ring furnished .055", .064", .073" thick.

Modulator (1954 Models): Disassembly - Carefully lift out hydraulic pistons and place in safe position so they will not be damaged. Take out cover attaching screws **while holding cover down** against spring pressure, then remove cover, diaphragm spring and diaphragm.

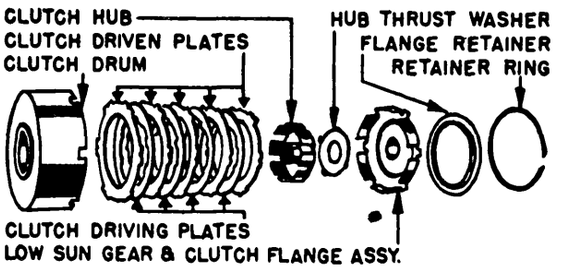
Inspection - Wash all parts in cleaning solvent, blow out all passages, then dry with air. Check modulator cover for cracks, check diaphragm for wear or cracks. Check spring for distortion or low tension. Inspect hydraulic pistons for nicks or wear and make sure they operate freely in modulator bores.

Reassembly - Place assembly Tool J-5389 in hydraulic piston bore in modulator, then assemble diaphragm and spring. Install two 10-24 x 3" guide pins (part of Pilot Stud Set J-3387) in modulator body and install cover over guide pins. Install attaching screws and tighten securely. Install hydraulic pistons with crowned end toward modulator lever and diaphragm.



Servo Cover (1954 Models): Disassembly - Remove retaining screw, lubrication valve bi-metal strip and retainer. Remove lubrication bypass valve plug and copper gasket, then remove bypass ball spring and ball. *NOTE - Do not remove modulator control lever.*

Inspection - Wash all parts in cleaning solvent, blow out all passages and dry with air. Inspect cover for cracks, nicks or burrs on mounting face. Check bypass ball spring and valve bi-metal strip for distortion. See that modulator lever operates freely without binding. *CAUTION - Lever must not bind on guide pin.*



Reassembly - Install valve bypass ball, spring and plug (use new gasket), tighten plug to 17-20 ft. lbs. Install bi-metal strip retainer, bi-metal and retaining screw and tighten screw securely.

Serv Cover (1955-57 Mod ls): Disass mbly - Remove pressure regulator reverse booster valve, valve guide and seal assembly by holding servo cover in a stationary position and pulling on protruding end of booster valve. Remove booster valve, spring and seat.

Inspection—Inspect cover for nicks or cracks. Using a small punch or similar tool, and working through the opening in the by-pass disc seat, exert pressure on the disc to make sure disc and spring are free and that disc is seating properly *(NOTE—*Do not remove disc seat unless there is evidence of damage). Inspect pressure regulator reverse booster valve springs for distortion or damage. Inspect pressure regulator reverse booster valve for galling or scoring and make sure it operates freely in bore in guide. Inspect snap ring for loose fit in groove. Inspect bore in valve guide for galling or scoring and check seal for distortion or damage. Check valve guide bore in servo cover for roughness or burrs and make sure that valve spring and guide spring and seat will seat properly in bottom of bore.

POWERGLIDE FRONT OIL PUMP

POWERGLIDE MULTIPLE DISC CLUTCH

Lubrication By-Pass Valve Assembly Replacement—If during inspection it is evident that the lubrication by-pass valve assembly is not functioning properly, correct as follows: Using a suitable tool remove the nylon by-pass disc seat, then remove disc and spring. Inspect disc for burrs, and spring for distortion. Inspect wall of by-pass valve cavity for roughness, nicks or burrs. Insert by-pass disc in its cavity to make sure its movement is not restricted. Remove disc from cavity. Replace any part that is defective. Install by-pass spring in its cavity in servo cover and install by-pass disc. With servo cover inner surface facing upward, position a new disc seat over its opening in cavity and press into place using a socket of proper size. It should be flush to .005" below inner surface of servo cover. *CAUTION—Under no circumstances should the by-pass disc seat that was removed be re-installed.*

Reassembly—Install pressure regulator reverse booster valve spring seat in bottom of bore in servo cover, then install valve and valve guide springs. Assemble booster valve and valve guide with the double seat of guide toward special snap ring on

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

valve. Place valve and guide into bore in servo cover, then with thumb and finger, press valve guide and seal into bore until guide is flush with surface of cover or slightly below. *(CAUTION—Do not press booster valve guide too far below surface of servo cover as this would place heavy spring pressure on guide).*

Front Pump: Disassembly—Slide stator support out of pump body, lift out pump gears (CAUTION—use extreme care not to drop or nick gears), remove and discard "O" ring seal.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect pump gears for wear, nicks, or other damage. Inspect pump body and pump face of stator support for nicks and scoring. Inspect pump body oil seal for excessive wear, damage, or evidence of leaking (see Oil Seal Replacement below). Inspect pump body bushing for galling or scoring, check bushing wear or clearance as directed below. Check pump gear clearances as follows:

1) **Pump Gear Clearances** - Install clean, dry gears in pump body, check clearance with feeler gauge.

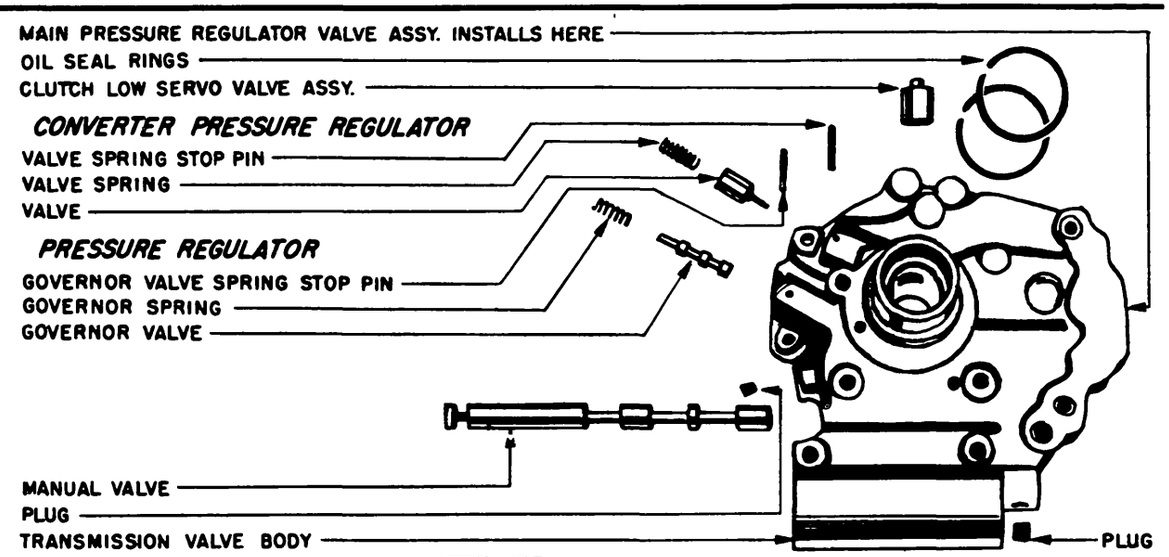
Driven Gear Clearance - .0025-.0055" clearance between outer diameter of gear and pump body.

Driving Gear Clearance - .003-.009" clearance between end of gear teeth and crescent.

Gear End Clearance - Place scale across face of pump body and measure clearance between scale and face of gears. This clearance should be .0005-.0015".

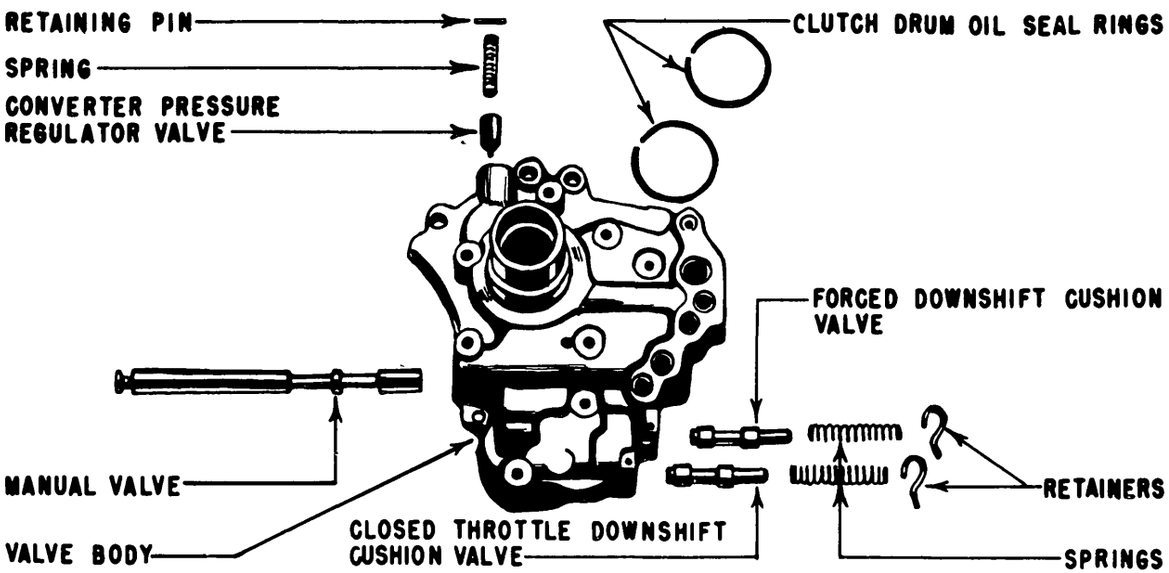
2) **Pump Body Bushing Clearance** - Temporarily install pump body on converter pump hub and measure bushing-to-hub clearance with a feeler gauge. This clearance should be .0005-.0015".

3) **Oil Seal Replacement** - Thread Oil Seal Removing Tool J-6793 into oil seal and attach sliding hammer to tool. Drive seal out of housing. Position a new seal, Part No. 3737894 in front pump and drive into place with Tool J-6839



Reassembly—Install new "O" ring seal in pump body, oil pump gears thoroughly with transmission oil and install in pump body, install stator support through pump body and driving gear and line up attaching bolt holes.

Rear Pump: Disassembly—Take out two screws and remove pump body plate, lift out pump gears.



Inspection—Wash all parts in cleaning solvent, blow out all oil delivery holes, dry with air. Inspect pump body for nicks and scoring, inspect gears for wear, nicks, or other damage. Check gear clearances (clearances are same as for front pump—see Pump Gear Clearances above). Inspect rear bearing for roughness but do not remove bearing unless replacement required (see Bearing Installation below).

Pump Bearing Replacement—Remove three retaining capscrews, lockwashers, and lockplate. Drive old bearing out. Press new bearing in place, install lockplate and retaining screws and lockwashers, tighten screws securely.

Reassembly—Oil pump gears thoroughly with transmission oil and install in pump body. Install pump body plate and two slotted attaching screws, tighten screws to 3½-5 ft.lbs. torque.

1954 POWERGLIDE VALVE BODY ASSEMBLY

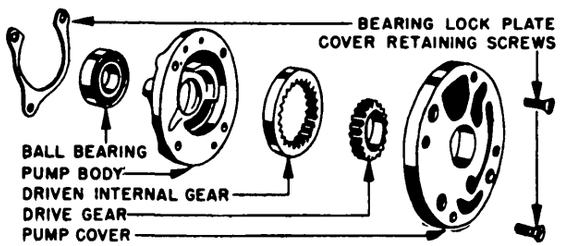
1955-57 POWERGLIDE CONTROL VALVE ASSEMBLY

Valve Body (1954 Models): Disassembly - Remove clutch low servo valve assembly (located in inner face of valve body), then support valve body on wooden blocks (face down). Use a small punch to drive out pressure regulator governor valve retaining pin from body, then remove pressure regulator governor valve spring and valve. Drive out converter pressure regulator valve retaining pin and remove converter pressure regulator valve spring and valve. Remove two clutch drum oil seal rings from oil delivery sleeve. Rings have interlocking ends.

Reassembly - Install all parts in reverse order of disassembly.

Valve Body (1955-57 Models): *CAUTION - See valve body production and service changes above.*

Disassembly—Using needle nose pliers remove the forced downshift cushion valve retainer from valve body and take cushion valve and spring from bore. Remove closed throttle downshift cushion valve in the same manner. Place valve body assembly, face down, on two wooden blocks of equal thickness and



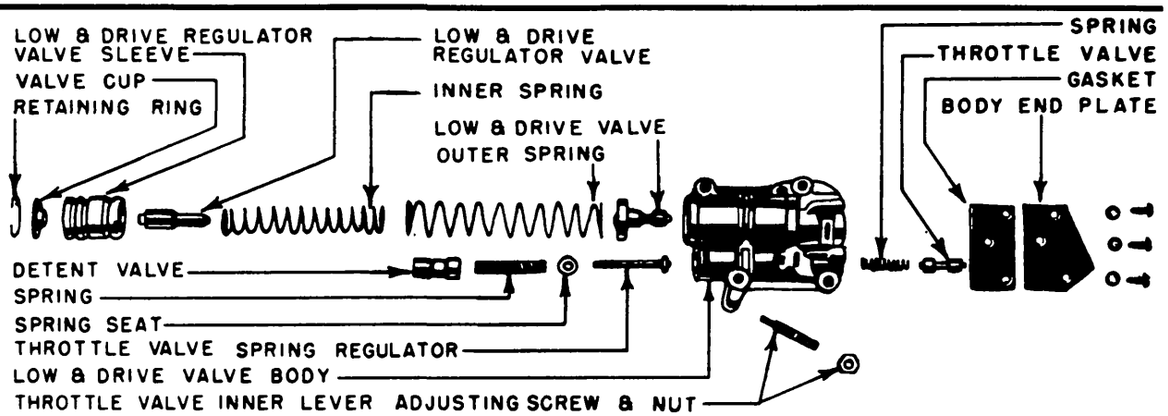
C NTINUED N NEXT PAGE

POWERGLIDE (C ntinued)

with a small pin punch drive out the converter pressure regulator valve retaining pin and remove spring and valve from bore. Remove the two clutch drum oil seal rings from oil delivery sleeve. Remove front and rear oil pump check valve from valve body.

Inspection—Wash all parts in clean solvent and blow dry with air. **Do not use a rag to dry these parts.** Check all springs for distortion or damage, and all valves for nicks, scores, burrs or galling, and for free movement of valves in their respective bores. Check oil seal rings for nicks or burrs and make sure that they are free in the ring grooves. Install rings in clutch drum and make sure that hooked ring ends have clearance.

Assembly—Place valve body, face down, on wood blocks. Assemble converter pressure regulator valve spring in valve and then, as an assembly, install in valve body bore. Install retaining pin. Assemble forced downshift cushion valve spring to valve and then as an assembly, install in valve body *(CAUTION*—Do not confuse the forced downshift cushion valve spring with the closed throttle downshift cushion valve spring. *The forced downshift cushion valve spring is the shorter of the two and is made of heavier gauge wire).* Assemble and install closed throttle downshift cushion valve spring in the same manner. Install front and rear oil pump check valve in valve body making sure it is flush with or below valve body face. Install the two clutch drum oil seal rings in grooves of oil delivery sleeve.



POWERGLIDE REAR OIL PUMP

Low-and-Drive Valve Body: ***CAUTION—Do not disturb Throttle Valve Adjustments (two adjusting screws—one in boss on valve body and one in throttle valve inner lever) unless required by installation of new parts. THROTTLE VALVE MUST BE ADJUSTED IF THESE SETTINGS DISTURBED (see Throttle Valve Inner Lever Adjustment).***

Disassembly—1) Remove valve body-to-side cover attaching bolts and lockwashers. While holding detent valve in place, use soft hammer to carefully tap inner face of side cover until it is free of the locating pins *(CAUTION*—Use care to keep parts from falling out and being lost or damaged while performing this operation).

2) Withdraw detent valve, spring, spring seat, and throttle valve spring regulator assembly from valve body. Remove throttle valve spring and throttle valve.

3) Use Pliers J-5403 to remove special snap ring retaining low-and-drive regulator valve cap, then remove the valve parts as follows: Valve Cap, Sleeve and Valve (as an assembly), Inner and Outer Springs, and Valve.

POWERGLIDE LOW & DRIVE VALVE ASSEMBLY (TYPICAL)

4) Take out two attaching screws and remove clutch exhaust cover plate ("L" shaped strip) from the side of the valve body.

5) Take out three attaching screws and lockwashers in end plate (CAUTION—exert pressure on plate while removing screws to prevent parts flying out), remove plate, remove valve parts as follows: Clutch Exhaust Secondary Control Valve, Spring, Stop (from upper valve bore), Clutch Exhaust Primary Control Valve Spring, Stop, Valve (from center valve bore), and throttle valve and spring (NOTE—some early cars used two springs, one inside the other).

6) Remove throttle valve outer lever assembly, shield, and inner lever assembly (CAUTION—do not disturb adjusting screw in inner lever unless required by parts replacement). Remove throttle valve lever shaft seal.

Inspection—Wash all parts in cleaning solvent, blow out all passages, dry with air. Inspect all valves for nicks, burrs, scoring, or galling. Check all valves for free operation in their respective bores. Inspect all vaive springs for distortion or damage. Inspect throttle lever assembly shaft for wear, scoring, or galling, see that shaft operates freely in side cover and that inner lever is tight on shaft. Inspect detent valve stop in side cover for distortion or damage, install new stop if necessary. Inspect locating pins in valve body and side cover for distortion or damage (one pin should be in side cover, other pin in valve body), replace pins if necessary. Inspect mating surfaces of valve body and side cover and make certain they are free of nicks or burrs.

Reassembly—1) Install low-and-drive valve in body bore (CAUTION—valve must be guided to prevent damage to the bore—use a piece of brake tubing inserted in valve shank bore at rear of valve body, engage nib on valve in end of tubing, move valve into position slowly). Install remaining low-and-drive valve parts in reverse order of disassembly (install regulator valve and cap on valve sleeve first and then install in valve bore as an assembly making certain inner spring is seated on sleeve). Compress assembly in valve bore while installing special snap ring, make certain ring properly seated in groove in valve body.

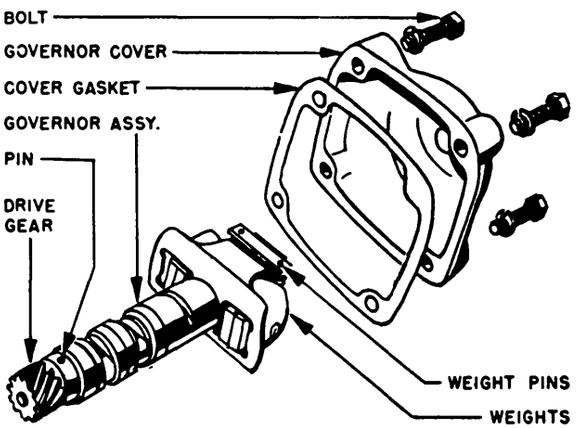
2) Install clutch exhaust secondary and primary valve assemblies (CAUTION—use care not to confuse these valve parts—primary control valve stop is the longer of the two stops, and primary control valve spring is the shorter of the two springs). Install throttle valve spring and valve in valve body, then install end plate and hold plate in position while tightening end plate attaching screws, tighten these screws to 2½-3½ ft.lbs. torque.

3) Install throttle valve spring regulator assembly in valve body and see that it is seated on throttle valve spring. Install detent valve spring seat, valve spring, and valve (thread pin of the throttle valve spring regulator assembly through the opening in the spring seat and valve).

4) Clamp side cover in a vise (face upward), align locating pin in side cover with hole in valve body, exert pressure on valve body to keep locating pin in the hole and at the same time compress detent valve in valve body bore and rotate valve body counter-clockwise until the locating pin in the valve body enters the locating hole in the side cover (CAUTION—make certain face of detent valve is resting against stop pin in side cover). Install attaching bolts and lockwashers, tighten bolts evenly to 3½-5 ft.lbs. torque.

5) Install throttle valve inner lever assembly in side cover, install new seal on shaft and into counterbore in cover, install shield. Install outer lever assembly on inner lever shaft, install outer lever attaching bolt from underside, tighten nut securely. ***If lever adjustments disturbed during overhaul, readjust throttle valve as follows:***

Throttle Valve Inner Lever Adjustment: Rotate throttle valve inner lever until it just contacts face of the detent valve. Hold lever in this position and turn adjusting screw until it just contacts flat surface of the step in the lever. Back off one complete turn and lock in this position by tightening adjusting screw lock nut securely.



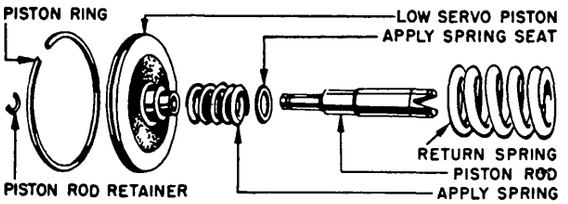
Governor: ***CAUTION—The only parts serviced for replacement are the governor assembly (complete), and driven gear. Governor should not require disassembly except for cleaning and removal of foreign material causing improper operation. See "Governor Driven Gear Replacement" below for disassembly & reassembly.***

C NTINUED N NEXT PA E

POWERGLIDE (C ntinu d)

Governor Driven Gear Replacement: A unit package containing a governor driven gear and pin, and two governor weight pins is available for service replacement. ***(CAUTION—The 1955 driven gear is not interchangeable with gears on previous models).*** Install new gear and pins in the following manner:

Installation—Cut off ends of governor weight pins and remove weights and governor valve. ***(NOTE***—Carefully protect governor valve to prevent damage. Weights are interchangeable from side to side). Drive out governor gear retainer split pin using a small punch. Support governor on 3/16" plates installed in exhaust slots of governor sleeve, place in arbor press and with a long punch, press gear out of sleeve. Carefully clean governor sleeve of chips and reinstall in arbor press. Position new gear in sleeve and with a suitable socket, press gear into sleeve until nearly seated. Then remove any chips that may have shaved off the gear hub and press gear in until it bottoms on shoulder. ***(CAUTION—It is important that a socket be used to prevent damage to thrust button on end of gear).*** Drill a new hole through sleeve and gear locating it 90° from existing hole, using a No. 24 (.152") drill. Install split pin retainer. Wash governor assembly thoroughly. Install governor valve and make sure that it operates freely. Install governor valve in bore of governor sleeve. Align governor weight pin holes in the governor thrust cap, governor weight assemblies and governor sleeve and install new pins. Crimp both pins to prevent them becoming dislodged. Check governor weight assemblies for free operation on pins.



GOVERNOR ASSEMBLY

Low Servo Piston: Disassembly—Place piston assembly in bench press supporting notched end of shaft on wooden block, install tool J-3377 (same tool used for Reverse Servo) on top of piston, compress spring sufficiently to enable rod retainer "C" washer to be removed from end of rod, relieve spring pressure, remove piston, spring, and washer from piston rod. Remove piston ring from piston.

Inspection—Wash all parts in cleaning solvent, dry with air. Inspect all parts for wear or damage. Install piston ring in low piston bore and check ring gap with feeler gauge. Gap should be .005-.010".

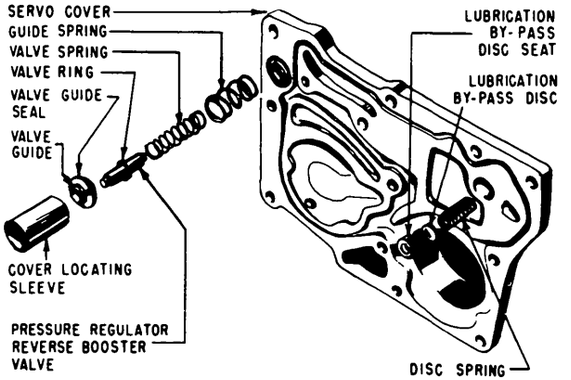
Reassembly—Assemble all parts on piston rod, compress spring in bench press and install piston rod retainer making certain that it is properly seated in groove. ***CAUTION—Spring pressure is 150 lbs. and assembly must be handled carefully.***

Reverse Servo Piston: Disassembly—Place assembly in bench press with spring end up, install tool J-3377 on spring retainer, compress spring sufficiently to enable retainer key locks to be removed, relieve spring pressure, lift off retainer, springs, and piston. Remove piston ring from piston.

POWERGLIDE LOW SERVO ASSY.

Inspection—Wash all parts in cleaning solvent, dry with air. Inspect all parts for wear or damage. Install piston ring in reverse piston bore and check ring gap with feeler gauge. Gap should be .005-.010".

Reassembly—Assemble all parts on piston rod, compress spring in bench press and install retainer locks, make certain locks seated properly in rod groove.



Planet Carrier Assembly: ***Should not be disassembled unless inspection below indicates overhaul required. See Planet Carrier Overhaul below.***

►*PLANET REVERSE RING GEAR AND DRUM ASSEMBLY PRODUCTION CHANGE (to accommodate a new .020" steel thrust washer):* Beginning with transmission serial number C-128-D, a new steel thrust washer is used between planet carrier and reverse gear and drum to prevent galling of thrust surfaces. A service package, Part No. 3721564, consisting of a Planet Reverse Ring & Drum Assembly, Part No. 3720472, and an Output Shaft Thrust Washer, Part No. 3720474, is available for service replacement on 1953-54 & Early 1955 cars.

Inspection—Wash in cleaning solvent, blow out all passages, dry with air. Inspect all gear teeth for nicks, scoring, or other damage. Check end clearance of planetary pinions with feeler gauge inserted between ends of pinion and thrustwasher. This clearance should be .006-.030". Check reverse sun gear rear thrustwasher for wear or damage. Inspect drum bushing for wear, scoring, or damage; inspect outer diameter of drum for scoring or burning. Check output shaft bearing surfaces for wear, nicks, or scoring. Check input pilot bushing for wear or scoring.

Planet Carrier Overhaul: ***If inspection (above) indicates that parts require replacement, proceed as follows:***

Disassembly—Place assembly in holding fixture or clamp in a vise with front end upward. Mark each pinion shaft and also mark planet carrier (use prick punch or other means) so that shafts can be

POWERGLIDE SERVO COVER ASSEMBLY

re-installed in same position ***(CAUTION***—pinion shafts are selective fit in carrier and location must not be changed). Then proceed as follows:

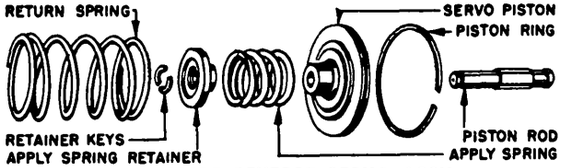
1) Remove pinion shaft lockplate screws, rotate plate counter-clockwise until it is free and remove the plate.

2) Starting with one short planet pinion, use a soft steel drift to drive on lower end of pinion shaft until shaft raised above the press-fit area of the output shaft flange, then insert tool J-4599 (one piece only —second piece of tool set used for reassembly) into short planet pinion from lower end and push shaft out until tool is centered in the pinion and shaft is removed. Remove short planet pinion from assembly. Remove tool from pinion, remove needle bearings and needle bearing spacer ***(CAUTION***—use care not to lose any of the needle bearings).

3) Remove **adjacent** long planet pinion (paired to the just-removed short pinion by using same thrustwashers) by repeating procedure in step (2) above. Then remove the pinion upper and lower thrustwashers.

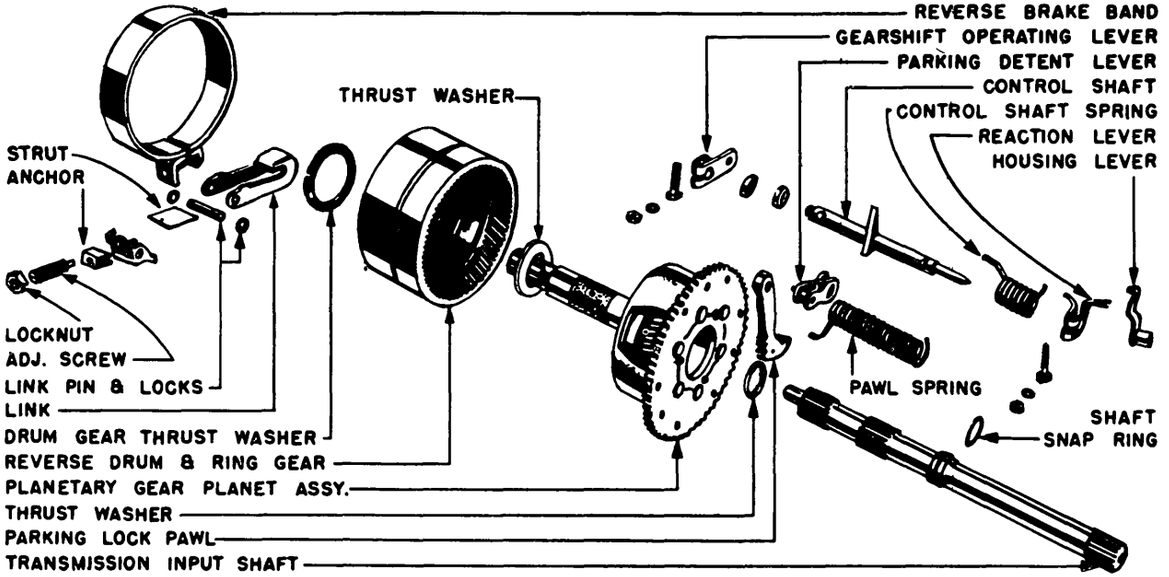
4) Remove all remaining planet pinions **in pairs** (short pinion first, followed by long pinion) by following procedures in steps (2) and (3) above.

5) Remove reverse sun gear and sun gear thrustwasher.



Inspection—Wash all parts in cleaning solvent and dry with air. Inspect all pinion gears and reverse sun gear for nicked or otherwise damaged teeth, inspect all thrustwashers for wear, nicks, or scores. Inspect needle bearings for wear and replace **all** needle bearings if worn excessively.

Reassembly—***CAUTION—Pinion shafts must be reinstalled in accordance with marks made before disassembly (shaft is selective fit in particular hole in carrier).*** Assemble and install parts as follows:
1) Install tool J-4599 in one long planet pinion, assemble needle bearing spacer and needle bearings in pinion (20 at each end) using cup grease to hold needle bearings in position.



CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

2) Install pinion assembly in planet carrier with tool centered in assembly and with thrustwasher at each end of pinion. *NOTE*—Long pinions are located opposite closed portion of carrier, short pinions are located opposite carrier openings. Feed the second part of tool J-4599 in from the top of the planet carrier *(CAUTION*—make certain tool picks up thrustwasher) and push first part of tool down and out at the lower end *(CAUTION*—make certain this tool picks up thrustwasher as it is pushed down). Lubricate correct pinion shaft (see Reassembly Caution above) and install it from top pushing the assembling tools out ahead of it. Turn shaft so that slot in upper end faces toward center of assembly, tap shaft down with a brass or soft steel drift until lower end is flush with lower face of carrier.

POWERGLIDE REVERSE SERVO ASSY.

POWERGLIDE PLANET CARRIER, REVERSE BAND, & PARKING LOCK

3) Assemble and install **adjacent** short planet pinion (paired with just-installed long planet pinion by using same thrustwashers) by repeating procedure in steps (1) and (2) above.
4) Install reverse sun gear thrustwasher and reverse sun gear.
5) Install all remaining planet pinions in **pairs** (long pinion first, followed by short pinion) by following the procedure in steps (1), (2), (3) above.
6) Check end clearance of planet pinions using feeler gauge inserted between end of pinion and thrustwasher. This clearance should be .006-.030".
7) Install pinion shaft lock plate with extended portions in line with pinion shaft slots, rotate plate clockwise until plate locks all pinion shafts and attaching screw holes line up. Install lock plate attaching screws and tighten to 2½-3 ft.lbs.

Input Shaft: Inspect shaft splines for wear, nicks, or other damage. Check spline fit in clutch hub, reverse sun gear, and converter hub. Inspect oil seal ring for wear and free fit in groove, remove ring (compress one end, push other end outward to free locked ends) and install ring in valve body bore to make certain hooked ends have clearance, then reinstall ring on shaft. Check snap ring in groove at forward end of shaft (this ring first used in 1953 transmissions and prevents shaft floating forward), replace if worn or damaged using snap ring pliers KMO-410.

Transmission Cas & Rear Bushing: Check case for cracks, inspect rear bushing for wear or damage and replace if necessary.

Bushing Replacement—Place transmission case in an arbor press with rear end up. Using a cape chisel, cut bushing and remove from bore in case. Install rear bearing in its bore in rear oil pump assembly and install rear oil pump in case to serve as a pilot when installing new bushing. Place transmission case in an arbor press with front end up. Place new bushing on bushing installer J-4276, with the square end of bushing against shoulder of installer. Insert in case, entering pilot of tool into rear bearing, and press bushing into place. Bushing is precision type and does not require reaming.

Low & Reverse Brake Bands: Inspect bands for wear, cracks, and scored or burnt lining. Lining is bonded to band. Inspect linkage for wear.

REASSEMBLY

AFTER ALL MAJOR UNITS REASSEMBLED (See Overhaul above), install units as directed below using ALL NEW GASKETS AND SEALS and tightening all parts evenly to SPECIFIED TORQUES.

CONVERTER HOUSING ASSEMBLY: *Install units:*

Valve Body: First install suction screen in oil sump *(CAUTION*—screen must be thoroughly cleaned), see that sealing ring is in place. Install two ¼—20 x 3½" guide pins (part of Pilot Stud Set J-3387) in two valve body attaching bolt holes, place new valve body gasket in position over guide pins, install valve body assembly. Install all attaching bolts *(CAUTION*—lower left bolt over accumulator bore is special self-locking type and must be installed in this position), tighten all bolts evenly in a criss-cross pattern to 7½-10 ft.lbs. torque. **Check manual valve and pressure regulator valve for free operation after all bolts tightened.**

Front Pump: Align holes in stator support with mounting holes in pump body, install two ¼—20 x 3½" guide pins (part of Pilot Stud Set J-3387) in pump mounting holes, use Driver J-4263-5 to install pump in converter housing *(CAUTION*—line up suction and oil delivery holes on left side of pump). Install five self-locking bolts through valve body and into pump, tighten all bolts evenly to 7½-10 ft.lbs. torque. *CAUTION—Check pressure regulator valve for free operation after bolts tightened and make certain that pump operates freely.*

Low-and-Drive Valve Body: Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in two valve body mounting bolt holes on left side of converter housing, place new gasket in position over guide pins, install valve body assembly. Install attaching bolts and lockwashers, tighten bolts evenly to 12½-15 ft.lbs. torque.

TRANSMISSION CASE ASSEMBLY: Install units:

Rear Pump: Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in pump attaching bolt holes, place new gasket in position over guide pins, install pump *(CAUTION*—align oil suction and delivery holes), tighten pump mounting bolts evenly to 12½-15 ft.lbs. torque.

Lubrication Pressure Relief Valve: Make certain that valve is clean and openings free from obstructions, see that valve disc and spring operate freely. Install relief valve in mounting hole in rear of transmission case and tighten securely.

Reverse Servo Piston, Band, & Drum: Compress piston ring with Ring Compressor J-3365, install servo piston in case with notch in shaft toward front of case. Install reverse brake band and strut assembly with thin end of band away from piston, thread adjusting screw in until it indexes with hole in anchor. Install bronze thrustwasher on reverse drum hub, install drum in case and into brake band. ***DO NOT adjust band at this point.***

Planet Carrier Assembly (1954 Models): Rotate rear pump so that drive lug is at top of pump, then install planet carrier assembly in case aligning slot on carrier shaft with pump drive gear lug *(CAUTION - Shaft must protrud out of rear bearing a minimum f 7/8" indicating proper s ating of drive lug in carri r shaft slot).*

CONTINUED ON NEXT PA E

POWERGLIDE (C ntinued)

Install Tool J-938 on rear of transmission case (thread shaft tool into rear end of output shaft and bolt tool yoke on rear face of case), then turn tool handle to seat output shaft in rear bearing and remove tool. Install universal joint front yoke, washer, lockwasher and bolt. Tighten bolt to 25-30 ft. lbs.

Planet Carrier Assembly (1955-57 Models): Rotate rear pump drive slot to top of pump, then fill drive pin hole in output shaft with cup grease and install drive pin. Install planet carrier assembly in drum positioning arrow on face of external gear of planet carrier at top center. *NOTE - On Late 1955-57 transmissions, a steel thrust washer is used between planet carrier and reverse ring gear and drum. See "Planet Reverse Ring Gear and Drum Assembly Production Change" above.* Install rear bearing locating snap ring in its groove in output shaft and install rear bearing using Tool J-5814. *NOTE - Groove in outer diameter of rear bearing should be toward rear of transmission.* Install rear bearing retainer in groove in outer diameter of rear bearing and attach to rear oil pump with screws and lockwashers. Tighten to 7-8½ ft. lbs. Install rear bearing rear locating snap ring in its groove in output shaft. Using Tool J-5814, install speedometer gear on output shaft. Center raised ground surface of output shaft so that it will mesh properly with speedometer driven gear. Install new "O" ring seal on speedometer driven gear fitting, then assemble driven gear in fitting and install as an assembly in bore in extension housing. Install retainer, attaching screws and lockwashers and tighten to 3½-5 ft. lbs.

Reverse Band Adjustment: Adjust band at this point. *See BAND ADJUSTMENT.*

Transmission Endplay Check & Adjustment: After planet carrier assembly installed in case, the correct thickness of the low sun gear-to-reverse sun gear thrustwasher must be determined for the correct transmission endplay of .007-.035" as follows:

►*1957 POWERGLIDE LOW SUN GEAR THRUST WASHER PRODUCTION CHANGE:* The "roller type" thrust washer (.078" thick) used in production at this location has been changed to a bronze thrust washer (.095" thick). When servicing all 1957 Powerglide clutch assemblies installed in 1953-57 cars where either the low sun gear thrust washer ("roller type" or "bronze type"), or the clutch drum thrust washer requires replacement, it will be necessary to replace the washer at both of these locations. The service replacement clutch drum thrust washer (untanged) Part No. 3745897 is .061" thick. Replacement low sun gear thrust washers are furnished in the following sizes for selective fitting: Part No. 3719296 (.095"); 3719297 (.120"); 3719298 (.145"). *See "Transmission Endplay Check & Adjustment Change" below.*

►*1957 POWERGLIDE TRANSMISSION ENDPLAY CHECK & ADJUSTMENT CHANGE:* The procedure for selecting and installing the service thrust washers in all transmissions using the 1957 clutch will be as indicated below for 1955-57 transmissions except that the low sun gear-to-reverse gear clearance will be .025-.050". *See "Thrust Washer Production Change" above.*

(1) Use Tool J-4260 to measure distance from face of transmission case flange to face of reverse sun gear in planetary unit (place tool bar against case flange, extend tool stem until it contacts gear face), **tighten thumbscrew to retain this tool setting.**

(2) Install bronze thrustwasher and clutch assembly temporarily on oil delivery sleeve.

(3) Without disturbing tool setting obtained in step 1 (above), place .120" steel washer over tool pilot (short plug on tool bar), install tool over clutch assembly with tool pilot entered in low sun gear and tool stem against gasket on rear face of housing. Use feeler gauge to measure clearance between face of low sun gear and steel washer on tool pilot. If clearance not within .007-.035", repeat this procedure with .095" or .145" steel washer on tool pilot.

(4) When correct clearance of .007-.035" secured in step 3 (above), note thickness of steel washer used on tool and **select bronze thrustwasher of same thickness** for installation on input shaft splines at final installation (below). Remove clutch assembly and thrustwasher from oil delivery tube.

►**Thrustwasher Note**—This bronze thrustwasher furnished in three thicknesses as follows: Part No. 3694467—.095", No. 3694468—.120", No. 3694469—.145".

Parking Lock Mechanism: Install parking lock lever shaft assembly in case, install seal over end of parking lock lever shaft and into counterbore in case **with lip seal toward inside of case.** Install flat washer and parking lock lever on end of shaft, push lever on shaft for clearance of .000-.010" between lever and washer, tighten clampscrew to 8-12 ft.lbs. Install parking lock pawl over pawl support rod, install parking lock pawl spring, wind up pawl spring (tool J-3383) until spring catches on case.

Input Shaft & Clutch Assembly: Install input shaft in clutch unit. Install bronze thrustwasher **selected in "Transmission Endplay Check & Adjustment" (above)** on reverse sun gear splines of input shaft *(CAUTION*—flat side of washer must be toward reverse sun gear). Install assembly in case indexing input shaft pilot with pilot in output shaft and mesh low sun gear with short planetary pinions.

Low Servo Piston & Band Assembly: Install release spring on servo piston rod, use Ring Compressor J-3365 to compress piston ring and install assembly in transmission case. Install low brake band over the drum. Install apply strut guide spring over piston rod, engage apply strut in piston rod slot and engage opposite end of strut in the band. Engage anchor strut assembly in band groove and locate opposite end of anchor over the adjusting screw. ***DO NOT adjust the band at this point.***

Governor: Install governor assembly in bore in transmission case *(CAUTION*—Governor must be allowed to rotate counter-clockwise as gear teeth mesh and care must be taken not to damage gear teeth). Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in governor cover mounting holes, place new gasket in position over guide pins, install governor cover, attaching bolts and lockwashers. Tighten cover bolts evenly to 6½-8½ ft.lbs. torque.

Extension Housing (1955-57 Mod ls): Position new "O" ring seal on transmission extension, then carefully install extension on transmission case. Tighten screws to 12-15 ft. lbs., then install oil seal with Tool J-5154.

TRANSMISSION & CONVERTER HOUSING ASSEMBLY:

1) Install manual valve in valve body and manual valve inner lever in converter housing. Index lever pin with pick-up slot in valve, set manual valve so that it protrudes 1 11/16" out from face of valve body. This places valve in Reverse position.

2) Install new valve body-to-transmission case gasket.

►*CAUTION:* Two different valve body-to-case gaskets are used with the early and late type valve bodies. THESE GASKETS ARE NOT INTERCHANGEABLE. *See "Control Valve & Gasket Production Change and Service Replacement Note" above for control valve identification and gasket differences.*

3) Place transmission manual valve lever in top detent position *(NOTE*—this is Reverse position and will align reaction lever so that it will index with manual drive inner lever in converter housing).

4) Place clutch drum thrustwaher in position on oil delivery sleeve.

5) Install two ⅜—16 x 3¾" guide pins (part of Pilot Stud Set J-3387) in two opposite converter housing mounting bolt holes, carefully bring transmission case and converter housing together making certain that reaction lever indexes properly with manual valve inner lever. Install all case-to-housing bolts and tighten evenly to 25-30 ft.lbs. Install special self-locking bolt through front face of converter housing and tighten this bolt to 25-30 ft.lbs.

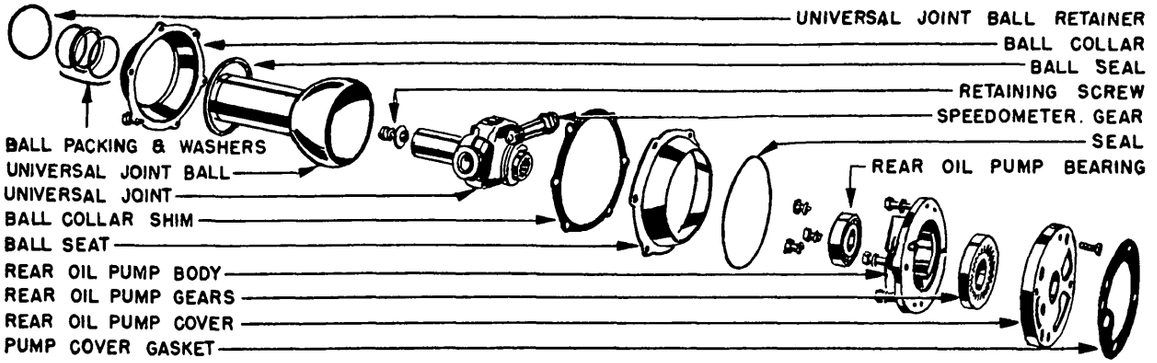
6) Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in two servo cover attaching bolt holes, place new gasket in position over guide pins. Install pressure regulator valve and inner and outer valve springs (see Note below) through servo and into case, install reverse servo return spring. Install servo cover over guide pins *(CAUTION*—see that pressure regulator springs and reverse servo spring seat properly in pockets in cover), maintain pressure on cover while installing and tightening cover bolts, tighten bolts evenly to 12½-15 ft.lbs.

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

7) Adjust Low Servo Band. *See Band Adjustment.*

►*NOTE: On 1954 models, install modulator cov r and a new gask t and tight n attaching bolts to 12½-15 ft. lbs.*



8) Install converter assembly in converter housing making certain that front pump drive lugs aligned with slots in converter pump hub. Install converter holding tool J-5384 using one housing bolt to hold tool (tool will prevent converter falling out while being installed on engine).

9) Check and adjust position of throttle valve outer ever. *See Throttle Linkage Adjustment.*

INSTALLATION IN CAR

1954 MODELS

1) Lubricate flywheel pilot with Lubriplate.
2) Raise transmission in place under car while lifting up on rear end, use pry bar if necessary to gain clearance at servo cover. ***Use extreme care not to bump or damage flywheel pilot.***
3) Turn torque converter until "X" mark on turbine cover is lined up with "X" mark on flywheel as nearly as possible (to nearest bolt hole). ***CAUTION—Alignment of marks is necessary to maintain balance.***
4) Remove converter holding tool. ***CAUTION—After tool removed, use extreme care not to allow converter to move forward which would disengage pump drive lugs from converter hub slots.***
5) Using guide pin installed in converter cover (pin can be made up by cutting head off a 5/16" or 3/8" bolt), carefully enter guide pin in flywheel hole, raise or lower transmission to align flywheel pilot, enter pilot in flywheel. ***CAUTION—DO NOT force transmission in place. guide transmission by hand until pilot enters and housings come together.***
6) Install transmission housing-to-bell housing bolts and tighten securely.
7) Remove guide pin and install flywheel-to-turbine bolts using 5/16"-24 or ⅜"-24 bolts as required. *See Flywheel & Converter Caution above.*
8) Install universal ball seat on rear of transmission case using a new "O" ring seal, connect universal joint, slide universal ball and collar forward on propeller shaft and fasten to case **using shim thickness determined in "Universal Joint Ball Adjustment" above** (under CHEVROLET UNIVERSAL JOINT BALL ASSEMBLY).

REAR OIL PUMP, UNIVERSAL JOINT, & JOINT BALL (CHEVROLET)

9) Connect linkage and other attachments. Fill transmission with lubricant (see LUBRICATION), adjust linkage (see LINKAGE ADJUSTMENT).

1955-57 MODELS

TRANSMISSION ASSEMBLY INSTALLATION: 1) Install assembly in handling fixture on hydraulic jack and roll into position under car. Raise transmission until converter housing is in approximate alignment with flywheel housing.

2) Remove converter assembly holding tool from converter housing. Then carefully align "X" mark on converter cover with "X" mark on flywheel.

►***CAUTION—After removing converter holding tool be careful that converter does not move forward causing disengagement of the pump hub drive slots from lugs of the front pump drive gear.***

3) Install one 5/16"—24 guide pin in converter cover. Rotate converter assembly until guide pin is in alignment with opening in flywheel housing. Maneuver transmission assembly until converter housing-to-flywheel housing bolt holes are in alignment and the flywheel pilot enters flywheel.

4) Install all but the uppermost three converter housing-to-flywheel housing attaching bolts. Through the opening in flywheel housing, remove guide pin from converter cover and install three flywheel-to-converter bolts, rotating flywheel as necessary. Tighten bolts to 25-30 ft. lbs.

5) Install filler tube and measuring dipstick. Install flywheel inspection hole cover. Install rear engine mountings (both sides). Remove engine support bar or cradle. Disconnect hydraulic jack handling fixture from transmission and remove jack.

6) On V8 cars, install starting motor. On all models, connect oil cooler lines and engage them in retaining clip on right side cover. Connect throttle valve control rod to throttle valve control outer lever and manual shift control rod (long rod) to bellcrank. On V8 cars, install breather pipe in cylinder block.

7) Engage internal splines of front yoke of front universal joint with external splines of transmission output shaft. Then slide front universal joint and propeller shaft as an assembly forward enough to connect rear universal joint.

8) Connect speedometer cable to transmission. On V8 cars, connect exhaust pipe to exhaust crossover pipe. On 6 Cyl. cars, connect exhaust pipe to exhaust manifold. Connect muffler to muffler support.

9) Lower car to floor and install the three remaining upper converter housing-to-flywheel housing attaching bolts through opening in toe-pan. Restore floor mat to its original position. Install spark plugs on all models. On V8 cars, connect battery ground strap and wires to starter solenoid.

10) Fill transmission with Automatic Transmission Fluid Type A. *See "Lubrication" above.*

1958-60 CHEVROLET POWERGLIDE

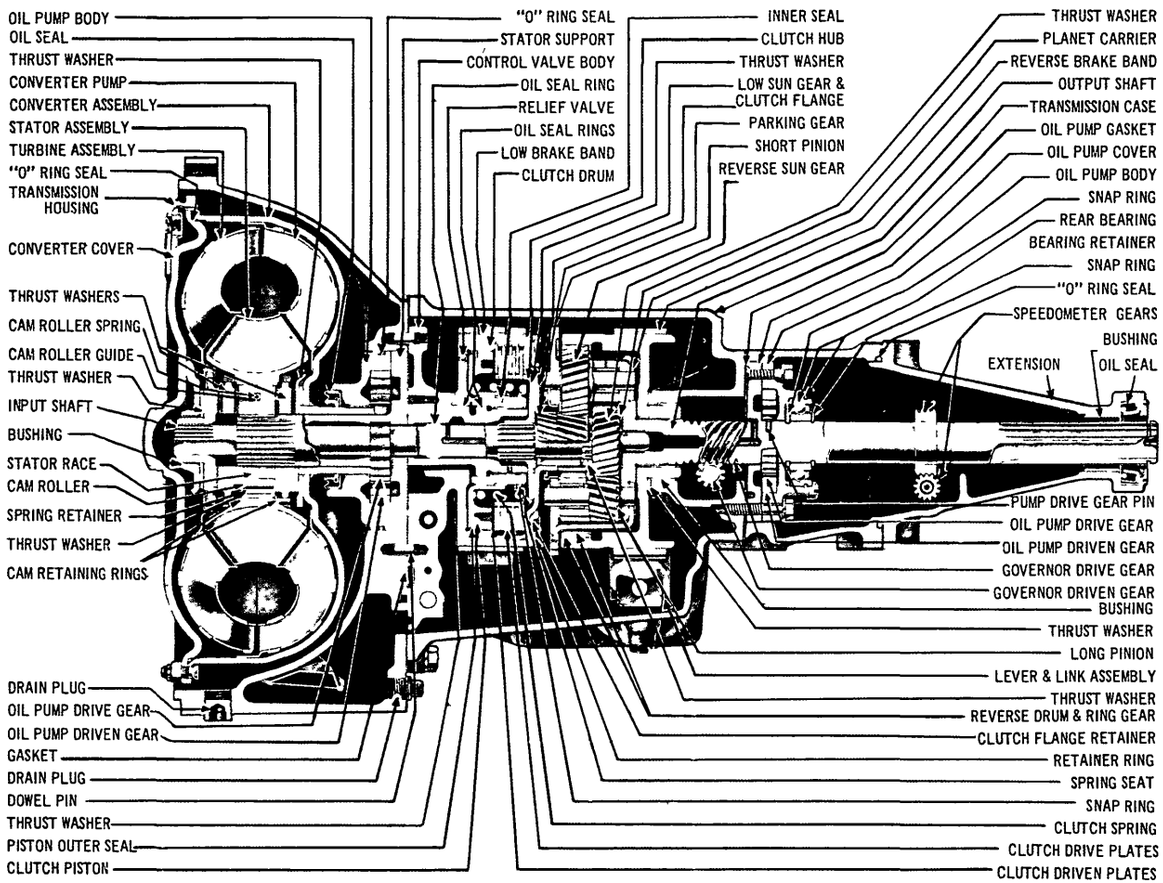
Ch vr let Pass. Cars (1958-60)
Chevrolet Corvette (1958-60)
Chevrolet Trucks, Series C10 & C20 (1960)

►CHANGES, CAUTIONS, CORRECTIONS

►*STARTING ENGINE BY PUSHING CAR (Pushing recommended rather than towing):* Place selector lever in Neutral "N" position. When car reaches speed of approximately 16 MPH. (20 MPH if road wet or icy with resultant poor traction), move selector lever to Low "L" position to crank engine. After engine is started, move lever to "N" for engine warm-up.

►*1958 LOW SERVO PISTON ASSEMBLY PRODUCTION CHANGE:* Starting with Transmission Serial No. C-1209-D, a new type low servo piston entered production. The later type piston assembly has separate piston head and shaft to permit incorporation of a "captive" cushion spring beneath piston head. Early type piston has the shaft pressed into piston head and a cushion spring is not used. With servo body cover removed, later type piston assembly can be identified by a pin retaining piston head to shaft which will be visible on piston head. Adjustment of low band is different for the two types of pistons. *See "Low Band Adjustment" below.*

►*1958 & LATER LOW BAND ADJUSTMENT CAUTION:* Adjustment of low band is different on later cars having the new type low servo piston assembly (see above). *For adjustment procedure, see "Band Adjustment" below.*



►*1958 REVERSE BAND LINKAGE PRODUCTION CHANGE:* Beginning with Transmission Serial No. C-108D, new Reverse Band Strut, Link & Pin Unit, Part No. 3756726 entered production. When a transmission built prior to above serial number is disassembled for any reason, the later type link, pin, and strut assembly should be installed.

►*1958 & EARLIER REVERSE BAND LINK OR PIN BREAKAGE CAUTION:* If breakage occurred with original reverse band pin or link, the transmission reverse oil pressure should be checked. Reverse servo apply pressure at 1000 RPM should be 240-275 lbs. (V8), 167-191 lbs. (6 Cyl.). If pressure is found to be excessively high, reverse booster valve assembly and pressure regulator valve should be checked for proper operation.

►*1958 V8 MODEL PRESSURE REGULATOR VALVE PRODUCTION CHANGE:* Beginning with Transmission Serial No. C-630D, a new pressure regulator valve which includes a dampener spring entered production. Installation procedures for later type valve are same as for previous type.

►*1958 PUMP-TO-CASE ATTACHING BOLT PRODUCTION CHANGE:* New "hollow" type bolt is used on later cars to replace the top rear pump-to-case attaching bolt. This bolt provides a vent which allows a more accurate dipstick reading when oil is added to transmission.

►*1960 TORQUE CONVERTER NOTE: Both "W ld d" and "Bolt d" typ convert rs are used in production. "W ld d" typ conv rters cannot be disass mbl d for ov rhaul.*

POWERGLIDE TRANSMISSION SECTIONAL VIEW

DESCRIPTION

Powerglide transmission is a 2-speed (forward) automatic type consisting of a torque converter and a planetary transmission unit providing automatic operation in "D" (Drive) range. Car starts in 1st speed and upshifts to 2nd, with selector lever in "D" (Drive). Low, Reverse, Neutral, and Park ranges are manually selected and controlled. This transmission is similar in design to previous models except that a vacuum modulator valve is included in control valve assembly and is operative only when transmission is in "D" (Drive) range. 1959 & 60 transmissions have a two-piece design low sun gear thrust washer; damper valve in pressure regulator valve assembly; vacuum modulation in "R" (Reverse) range; and reversible type clutch driven plates (not marked as with former plates).

LUBRICATION

Check oil every 1000 miles. ***NOTE - It is not necessary t chang il very 25,000 mil s as specified for previous models.*** **Engine and transmission must be at normal operating temperature, and selector lever in "N" (Neutral). DO NOT OVERFILL.**

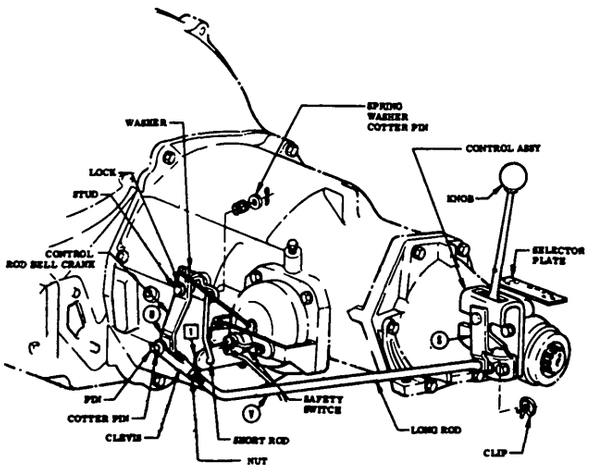
►*CONVERTER DRAIN NOTE:* There is no drain plug on converter unit. Oil trapped in converter need only be replaced when transmission disassembled for overhaul.

Recommended Fluid - Use Automatic Transmission Fluid Type "A" (Suffix "A") as furnished in containers bearing AQ-ATF-A number. *NOTE - If necessary, Automatic Transmission Fluid Typ "A" can b used.* **Capacity** - 3½ qts. (1958-59); 4½ qts. (1960 Pass. Cars & Trucks) refill after transmission case drained. 10½ qts. (1958-60 Pass. Cars); 10 qts. (1960 Trucks) after overhaul with transmission and torque converter drained. *CAUTION - Above sp cifications ar approximate. Final fluid level must be checked with dipstick.*

►***OIL FILLER NOTE*—Use of Oil Filler Tube & Funnel No. J-4264 recommended to facilitate filling. This assembly is vented (transmission not vented and may blow-back causing oil spillage if vented filler not used).**

►***LOW OIL LEVEL CAUTION—If oil level in transmission found consistently low, check for internal and external oil leaks. See "OIL LEAKAGE OR HIGH OIL CONSUMPTION" in TROUBLE SHOOTING.***

CONTINUED ON NEXT PAGE



POWERGLIDE (C ntinued)

Draining & R filling: *NOTE - Draining & refilling is n t r commend d xcept at time of overhaul.* With transmission at normal operating temperature, remove transmission drain plug. *NOTE - It is not necessary to drain converter.* To refill transmission, install drain plug and install recommended amount of fluid (see "Capacity" above). Operate engine with transmission in "N" (Neutral) until oil warms up, then add sufficient oil to raise level on dipstick to FULL mark. *DO NOT OVERFILL.* If converter was emptied, follow procedure above and add necessary amount of additional fluid.

LINKAGE ADJUSTMENT

►*THROTTLE LINKAGE ADJUSTMENT NOTE: See CARBURETOR n car m del pages.*

Manual C ntr l Linkage (Except Corvette): Place gear selector lever in "D" (Drive) position, then disconnect swivel on shift control rod at shift control lever on steering column mast jacket in engine compartment. Position shift lever on transmission in "D" (Drive) position. Adjust position of swivel on shift control rod for free entry into shift lever on steering column mast jacket, then install nut and tighten. Check transmission shifts in all ranges.

C RVETTE MANUAL CONTROL LINKAGE

Manual C ntrol Linkage (Corvette): Place control rod bellcrank (U) in "Park" position, then set control shaft lever (S) in "Park" position. With both bellcrank and lever held in "Park" position, assemble control rod (V) to lever (S), then adjust clevis on rod (V) for easy entry into lever (U).

Neutral Safety Switch (Except Corvette): Located on steering column mast jacket under instrument panel. Place selector lever in "N" (Neutral) position and loosen two screws securing neutral safety switch retainer. While holding ignition switch in "Start", adjust position of neutral switch until engine starts cranking. Hold switch in this position and tighten retaining screws. Check adjustment by testing for cranking with selector lever in "N" and in "P" positions.

N utral Safety Switch (Corvett): Located on left side of transmission case and linked to transmission manual control lever. Adjust switch so engine will start only with transmission selector lever in "N" or "P"

BAND ADJUSTMENT

►*BAND ADJUSTING NOTE: Band adjustment not ordinarily required in service (bands adjusted when reassembling transmission). Reverse band adjustment requires removal of Servo Cover Assembly (see Disassembly data).*

►*1958 LOW SERVO BAND ADJUSTING CAUTION:* Because of two different low servo pistons used during production *(see "1958 Low Servo Piston Assembly Production Change" above),* it will be necessary to identify the piston used to obtain correct adjustment. With servo cover removed, identification of piston can be made by the pin which retains head on shaft (later cushion spring type); or piston head without pin (early type).

Low Servo Band: Adjusting screw located on left side of transmission case under adjusting screw cover. To adjust band, remove adjusting screw cover and tighten low servo adjusting screw to 5-7 ft. lbs., using a torque wrench, Tool J-5853 or equivalent. *NOTE - Rotate input and output shafts simultaneously to properly center low band on clutch drum.* Back adjusting screw off **4 turns** (except early 1958 models with low servo piston having shaft pressed into head and no cushion spring see *"1958 Low Servo Piston Assembly Production Change" above).* **3 turns** (Early 1958 Models). Tighten locknut securely and install adjusting screw cover. *CAUTION - The amount the adjusting screw should be backed off after tightening to 5-7 ft. lbs. is not an approximate figure; it MUST be exactly as specified.*

Reverse Servo Band: *CAUTION - Band adjustment must be verified by actual measurement of reverse piston travel.* Rotate reverse drum to center it in reverse band, then using Tool J-4277, tighten adjusting screw to 5-7 ft. lbs. **Back screw off 2½ turns.** Check for proper adjustment as follows: Measure distance from face of reverse piston outward to the side of case with piston in its retracted position (inboard) with a small scale, then record this dimension. Pull reverse piston outward to its full travel by grasping its hub with a pair of pliers, then again measure distance from face of piston to outboard side of case. The difference between the two measurements should be 5/32-7/32" (1958); 3/32-5/32" (1959-60). If travel is too great, tighten adjusting screw. If too little, loosen adjusting screw. Recheck piston travel after adjustment. Tighten adjusting screw locknut to 20-25 ft. lbs.

TROUBLE SHOOTING

CLOSE THROTTLE DOWNSHIFT "CLUNK": May be caused by: High engine idle speed. Faulty downshift timing valve (replace valve). High mainline pressure caused by; Vacuum hose to modulator leaking or disconnected. Modulator diaphragm ruptured. Sticking valve (pressure regulator booster valve, pressure regulator valve, or modulator valve).

MOMENTARY RUN AWAY IN LOW UP TO 30 MPH (WIDE OPEN THROTTLE ACCELERATION): May be caused by a broken forced throttle cushion valve spring retainer. Check mainline pressure which will be lower just prior to shift, and the stall pressure will be low if the faulty transmission operation is caused by a broken retainer. *See "Closed & Forced Throttle Valve Spring Retainer Production Change" above.*

EXCESSIVE SLIPPAGE (High engine speed in relation to car speed, poor acceleration, or engine runs away on turns).
1) In all Speed Ranges—Low oil level. Incorrect control linkage adjustment. Air leak in oil pump suction pipe. Low front oil pump pressure.
2) In Drive Range—Incorrect control linkage adjustment. Damaged or leaking clutch piston seal (worn or burned clutch plates resulting from partially engaged clutch).
3) In Low Range—Incorrect control linkage adjustment. Low Band out of adjustment. Sticking accumulator valve, modulator lever, or modulator valve. Damaged or worn Low Servo Piston Ring resulting in poor band application or excessive oil leakage into clutch apply circuit causing partial clutch application and possibly burned clutch plates (check by connecting pressure gauges to Low Servo Apply and to High Clutch test points—there should be no pressure indicated at High Clutch point with selector lever in "L").

CAR CREEPS (Forward or Backward).
1) With Control Lever in Neutral—Incorrect control linkage adjustment. Clutch piston vent valve stuck closed. Clutch plates sticking or incorrectly assembled (not "stacked" in correct order).
2) Creeps forward with Control Lever in Reverse or backward with Lever in Low—Incorrect control linkage adjustment.

CAR WILL NOT MOVE (Rear wheels may be locked or free).
1) With Control Lever in any range (rear wheels free). If this occurs at other times than after reversing car, see causes listed under **EXCESSIVE SLIPPAGE** above. If this occurs only after reversing car (indicating loss of front pump pressure) check: Rear pump air leakage into front pump suction line (causing front pump to lose its prime). Rear pump gasket leakage. Front pump clearance excessive.
2) With Control Lever in any range (rear wheels locked). Parking pawl lock engaged. Broken parts in transmission. Parking brake applied.
3) With Control Lever in Drive Range (rear wheels free). If engine runs away and transmission is hot, check for: Low radiator water level, clogged oil cooler, sticking thermostatic valve, or dragging Low Range Band (causing over-expansion of clutch parts due to excessive heat).

SHIFTS ARE ROUGH.
1) Low-to-Drive Shift (car in motion). Incorrect Low Band adjustment. Clutch plates worn or binding. Modulator control lever or piston sticking (will cause excessive pressures). Accumulator dump valve orifice plugged.
If engine speeds up during this shift—Check for incorrect low band adjustment and worn or binding clutch plates.
2) Drive-to-Low Shift. Incorrect Low Band adjustment. Accumulator piston stuck closed. Modulator control lever or piston stuck (will cause excessive pressure).
3) Neutral-to-Reverse. Incorrect reverse band adjustment. Accumulator piston stuck closed. Modu-

C NTINUED N NEXT PAGE

POWERGLIDE (C ntinued)

lator control lever or piston stuck (will cause excessive pressure).

CHATTERS WHEN STARTING.

1) **In Low Range.** Incorrect Low Band adjustment. Worn or rough band, scored drum. Clutch not disengaging properly due to distorted or binding plates, sticking clutch piston, sticking piston vent valve, or damaged or worn Low Servo Piston Ring allowing oil leakage into clutch apply circuit and causing partial clutch application (see tests for Excessive Slippage in Low Range above).

2) **In Drive Range.** Incorrect Low Band or Reverse Band Adjustment. Bands worn or rough, drums scored.

3) **In Reverse Range.** Incorrect Reverse Band adjustment. Worn or rough band, scored drum. Reverse ring gear and drum bushing worn or damaged.

REVERSE OPERATION JERKY OR DRAGGING.

1) Clutch plates are incorrectly assembled (not "stacked" properly) or sticking. Clutch piston vent valve stuck closed.

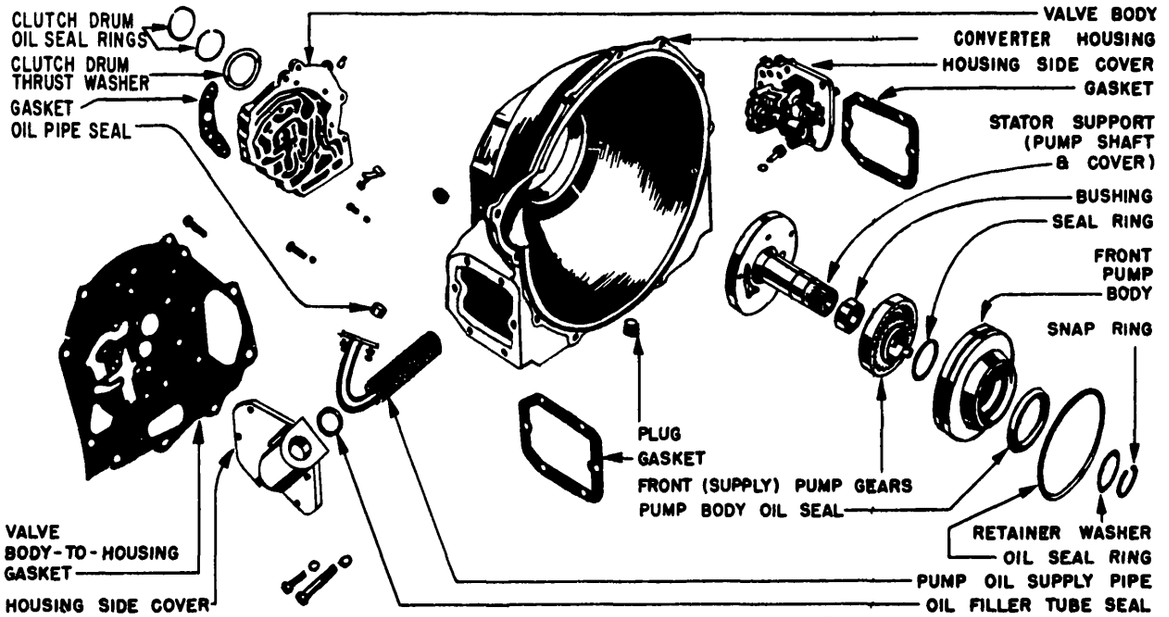
REVERSE CAN NOT BE ENGAGED WITH ENGINE RUNNING: If reverse can only be engaged when engine not running, check for accumulator snap ring being out of place (allowing accumulator valve and body to be forced against clamp nut on parking lock lever shaft and apply spring assembly, blocking shift into reverse). *NOTE*—Above condition will not prevent shift into Low Range).

DRIVE-TO-LOW or LOW-TO-DRIVE SHIFT DIFFICULT: May be caused by improperly drilled high clutch feed orifice in valve body resulting in slow clutch application in Drive Range and slow clutch release when shifting from Drive to Low (restricted orifice will cause slow oil flow). Check by connecting pressure gauges to Low Servo Apply and to High Clutch (low servo release side) and noting pressures as follows:

1) Move selector from Neutral to Drive with engine idling. If pressure builds up much more rapidly on Low Servo Apply gauge than on High Clutch gauge, a restriction in the passage (undersized orifice) is indicated.

2) Move selector from Drive to Low. Pressure in High Clutch gauge drops slowly, oil drainage from clutch is restricted. NOTE—This will result in slow Low Band application and clutch drag (may cause burned clutch plates).

HIGH CLUTCH PLATES BURNED OR CLUTCH FAIL



►*CAUTION—When High Clutch failure noted, following tests should be made before transmission removed, and transmission should also be carefully examined after removal and disassembly.*

1) Connect pressure gauges to Low Servo Apply, High Clutch (low servo release side), and to Reverse Servo points. Operate engine to supply oil pressure.

2) Place selector lever in Drive position and note pressure build-up in High Clutch gauge. Slow build-up indicates restriction in high clutch apply orifice resulting in clutch slippage and burned plates.

3) Place selector lever in Low position. High Clutch gauge should not show any pressure. Pressure at this point indicates leakage past Low Servo Piston Ring resulting in partial clutch application and burned clutch plates.

4) Place selector lever in Reverse position. High Clutch gauge should not show any pressure. Pressure at this point indicates leakage between the converter "out" and low servo "release" channels in valve body or damaged Housing-to-Valve Body gasket. This condition will cause partial clutch application and burned clutch plates.

POWERGLIDE TURBINE HOUSING & FRONT OIL PUMP

NOISE IN TRANSMISSION.

1) **Buzzing Noise (All Ranges).** Low oil level. Pump gear interference with crescent in pump. Pump check valve not seating.

2) **Ringing Noise in Converter.** Low oil level. Air leak in pump suction line (pump not seated properly) resulting in low oil level in converter. Pressure regulator valve stuck (closing converter inlet port). Leakage in oil line between front pump and regulator valve.

3) **Clicking Noise.** Incorrect manual linkage adjustment (causing interference between parking lock pawl and gear).

4) **Whining Noise.** Transmission gear teeth worn. Pump gear clearance excessive or pump gear bushings worn.

FUEL CONSUMPTION EXCESSIVE.

1) **Transmission Causes.** Converter stator freewheeling cams and roller incorrectly assembled. Clutch piston vent valve stuck open.

TRANSMISSION OIL BEING FORCED OUT OF FILLER PIPE: Caused by aeration and foaming of the oil due to one or more of the following:

NOTE—This condition may also cause Loss of Power and Lower Stall Speed (due to converter turbulence and lower pressures in control circuits).

1) Oil level too high allowing planet carrier to revolve in oil and aerate it. Correct by lowering oil level to correct point (see LUBRICATION) and driving car for 5 miles to work out air bubbles.

2) Oil suction pipe split, seal damaged, bore for suction pipe in housing too deep, or suction pipe retainer ears bent (preventing proper compression of the seal) resulting in air leaks in oil suction line.

3) Sand hole in suction bore of transmission case or housing or in suction cavity in valve body resulting in air leaks in oil suction line.

TESTING

►*TESTING CAUTION*—Transmission oil level must be checked and corrected (see LUBRICATION) and *transmission must be warmed up before tests made.*

Warming Transmission: Transmission must be warmed by road driving or in the shop as follows before checking for oil leakage or other trouble.

Road Warm-Up - Drive car for approximately 5 minutes with frequent stops and starts (to approximate heavy-traffic conditions).

Shop Warm-Up - Set hand brake tightly, place selector lever in "D" (Drive) range, start engine and run for 2 minutes at 750 RPM.

►*CAUTION: Recheck oil l vel after warm-up and b for making following tests.*

ROAD TEST: Road test car, to determine transmission shift points as indicated in table.

SHIFT PATTERNS ①

6 Cyl. Eng.

Throttle Position	②Upshift	③Downshift
Light Throttle ④	12-15 MPH	⑤ 10-13 MPH

① - Transmission in "D" (Drive) Range
② - From Low to High ③ - From High to Low
④ - Light Throttle on Upshift
⑤ - Closed Throttle on Downshift

►*STALL TEST NOTE: Stall t sting of transmission is not recomm nded.*

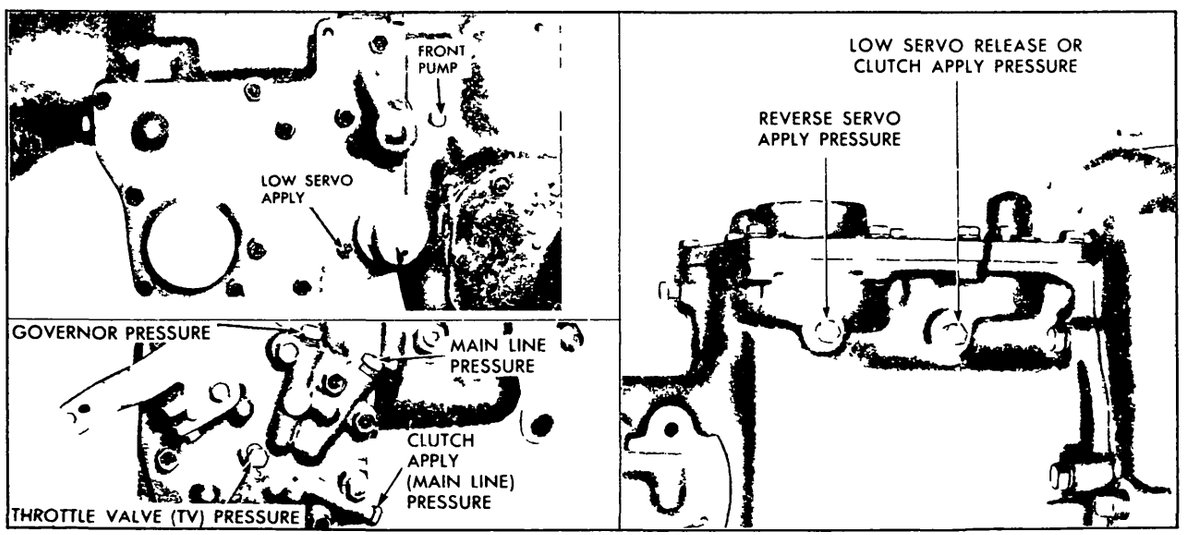
PRESSUR E TESTS: Install pressure gauge hose connections at low servo apply (main line), clutch (release side of low servo), throttle valve, governor test points on transmission (see illustration) Gauge lines should be run into driving compartment by pushing aside steering column mast jacket seal, and connected to Gauge Set J-4872-A

Wid Open Thr ttl Upshift Pr ssure: This shift should occur at 82-90 lbs pressure (V8 Eng), 68-74 lbs pressure (6 Cyl Eng) as indicated on low servo (main line) gauge After shift is completed, pressures on both low servo apply and high clutch gauges should indicate similar readings If pressures are correct and clutch slippage is felt, mechanical trouble in clutch is indicated If high clutch pressure is more than 5 lbs lower, check for leak in high pressure line between low and drive valve body and high clutch

Idle Pressure in "Drive" Range: *NOTE - In addition to oil pressure gauges, a vacuum gauge is required for this test* With parking brake applied and shift selector lever in "D" (Drive) range, adjust engine speed until a steady 16" of vacuum is indicated on vacuum gauge Low servo apply (Main line) pressure should be 60-70 lbs (V8 Eng), or 55-65 lbs (6 Cyl Eng) If pressures not within this range, check the following Pressure regulator valve, Vacuum modulator valve, or Booster valve stuck Leak at low servo piston ring (between ring and bore) or at low servo piston rod (between rod and bore) Leakage at valve body-to-case gasket Leak between valve body and housing Front pump clearances not correct Leak at low drive valve body (check gasket and shifter valve) Check passages in transmission housing for porosity Loose suction screen connection

Manual Low Range Pressure: Connect a tachometer, place selector lever in "L" (Low) range, and adjust engine speed to 1000 RPM with car stationary Low servo apply (main line) pressure should be 114-127 lbs (V8 Eng), 70-80 lbs (6 Cyl Eng) Pressures not within this range indicate the following possibilities Partially plugged oil suction screen Broken or damaged ring in low servo Pressure regulator valve stuck Leak at valve body-to-case gasket Leak between valve body and housing Leak at servo center Front pump clearances not correct

Drive Range Overrun (Coast) Pressure: With car coasting in "D" (Drive) range at 20-25 MPH and engine vacuum at approximately 20", low servo (main line) pressure should be 47-53 lbs (V8 & 6 Cyl Engs)



Throttle Valve Pressure: Pressures will range from 0-63 lbs (V8 Eng), 0-50 lbs (6 Cyl Eng), depending on accelerator position Improper throttle valve pressure is usually the result of trouble in low and drive valve body providing throttle valve linkage is properly adjusted

G v rn r Pressure: Governor pressure is relative to transmission output shaft speed and can be checked in terms of MPH by referring to following table

Governor Pressure

Car Speed (MPH)	Pressure	Car Speed (MPH)	Pressure
5	2-4 lbs	35	47½-53½ lbs
10	8½-13 lbs	40	55-62 lbs
15	21-27½ lbs	45	63½-71½ lbs
20	31½-34½ lbs	50	73½-82 lbs
25	35½-40 lbs	55	84-93½ lbs
30	41-46 lbs	60	95½-106 lbs

Reverse Pressure: With parking brake applied, place selector lever in "R" (Reverse) position and set idle speed at 1000 RPM Pressure reading on reverse servo apply (mainline) gauge should be 240-275 lbs (V8 models with early type pressure regulator valve), 215-245 lbs (V8 models with later type pressure regulator valve), 167-191 lbs (6 Cyl models) If pressures are within limits but operation in reverse is faulty, reverse band requires either adjustment or replacement (transmission overhaul required) If pressure is below limits, the following should be checked Partially plugged oil suction screen Broken or damaged reverse servo piston ring Pressure regulator valve or booster valve stuck Leak at valve body-to-case gasket Leak between valve body and housing Front pump clearances not correct Leak between piston rod and bore

POWERGLIDE PRESSURE TEST POINTS

REMOVAL FROM CAR (EXCEPT CORVETTE)

►*1959-60 POWERGLIDE DISASSEMBLY & REASSEMBLY*

CAUTION Before removing converter assembly from flywheel, scribe a line on both units so they may be installed in same position All flywheels are marked with a stripe of white paint to indicate "heavy" side of engine and all transmissions have a stripe of blue paint across ends of both converter housing and cover to indicate "light" side These paint markings must be aligned as closely as possible during assembly to obtain best balance conditions Flywheel assemblies used with automatic transmissions have six transmission attaching bolt holes instead of three The additional holes are used to permit accurate indexing of converter to flywheel Only three of the bolt holes will be used for actual attachment

Transmission & Torque Converter are removed as an assembly *CAUTION—Torque converter is not retained in housing as on previous transmission and special holding tool must be used to prevent converter falling out when transmission assembly removed.*

TRANSMISSION ASSEMBLY REMOVAL: Raise car on hoist (see "Jacking & Hoisting" in Suspension & Wheel Alignment Section), then proceed as follows

1) Drain transmission case, then remove transmission filler pipe Disconnect oil cooler lines, vacuum modulator hose, and speedometer drive cable fitting at transmission Disconnect body ground strap

2) Disconnect manual and throttle valve control lever rods from transmission, then disconnect propeller shaft at transmission Install suitable transmission lift to jack or other lifting device and attach to transmission

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

3) Disconnect engine rear mount on transmission extension, then remove transmission support crossmember. *CAUTION - Use care to remove any shims which may be installed between extension mounting b ss and crossmember. The same number of shims must be installed as these affect drive line angle.*

4) Remove flywheel cover, then using a jumper to turn the engine, remove flywheel-to-converter attaching bolts. Lower rear of ttansmission slightly so that the three upper transmission housing-to-engine attaching bolts can be reached (use a universal socket and approximately a 39" extension). Remove upper bolts. *CAUTION - Rear of transmission must not be lowered too far as distributor housing on engine may be forced against dash board.*

5) Support engine at oil pan rail with a jack, then remove remainder of transmission housing-to-engine attaching bolts. Remove transmission by moving slightly to the rear and downward. Install converter housing holding tool, J-5384, then remove transmission from beneath car. *CAUTION - Do not tilt front of transmission downward prior to installing Tool J-5384, as conv rt r may fall out of transmission.*

DISASSEMBLY—TRANSMISSION

►**DISASSEMBLY & REASSEMBLY CAUTION:** ***CLEANLINESS IS EXTREMELY IMPORTANT when opening up transmission. Thoroughly CLEAN exterior of case first, CLEAN each part as removed with cleaning solvent or gasoline and dry with air—do not use wiping cloths which will leave lint on parts. Store all parts in clean storage bins.***

►*1958-60 DISASSEMBLY CAUTION:* To prevent bending manual valve and manual valve inner lever, the manual valve should be moved into the position that places it as far as possible into its bore. Before separating the two case sections, place manual valve selector lever in "L" (Low) position.

DISASSEMBLY OF TRANSMISSION (Into Major Units): 1) Place transmission on bench (use holding fixture J-3361) and remove all units as indicated below.

2) Remove converter assembly holding tool J-5384 from housing, remove converter assembly by pulling it straight out of housing.

3) Take out right side cover attaching bolts, remove side cover, gasket, and oil pump suction screen.

4) Take out Low & Drive Valve Body attaching screws on left side of transmission case, remove drive body assembly and gasket. *CAUTION - Do not remove outer l ver assembly from valve body (this retains inner lever assemble in body).* Remove vacuum modulator and pushrod.

5) Loosen all servo cover bolts slightly and break servo cover loose if it sticks to case (reverse servo spring and pressure regulator spring bear against cover) **using care not to allow cover to tip** which may damage or break tip of pressure regulator valve. Use guide bolts to maintain cover alignment or turn all cover bolts out evenly while exerting pressure on cover, then lift cover and gasket straight off until cover clears tip of pressure regulator valve. Remove reverse servo spring and pressure regulator springs, lift regulator valve out.

►***CAUTION—Handle valve carefully to prevent damage and store it by itself to avoid nicking or scratching of the polished surfaces.***

6) Remove low band adjusting screw cover, loosen low band adjusting screw locknut using tool J-4277 (see Tool Modification below), and tighten low band adjusting screw to hold clutch assembly in place.

►***CAUTION—Make sure low piston assembly does not fall out of bore and become damaged.***

►**Tool J-4277 Modification Note**—Low band adjusting screw has recessed head for Allen wrench. To use tool, remove screwdriver retainer and special screwdriver from tool, use ¼" Allen wrench in place of screwdriver in tool.

7) Working from inside of converter housing, remove converter housing-to-transmission case self-locking bolt. Remove converter housing-to-transmission bolts and lockwashers and install two 3/8" - 16 x 3¼" guide pins (Part of Pilot Stud Set J-3387). Shift transmission into "Low" and then carefully separate transmission from converter housing. Remove valve body-to-transmission case gasket.

8) Remove manual valve from valve body on rear of converter housing, remove manual valve lever from housing, remove bronze thrustwasher from valve body oil delivery sleeve.

►***CAUTION—Handle manual valve carefully to prevent damage and store it by itself to avoid nicking or scratching of the polished surfaces.***

9) Take out all bolts and lockwashers attaching valve body to converter housing and front pump to valve body. Remove valve body and gasket.

►***CAUTION—Handle valve body and valves carefully to protect them from damage.***

10) Use Front Pump Driver Tool J-4263-5 to remove pump assembly from converter housing.

11) Loosen low servo band adjusting screw to free clutch assembly, remove input shaft, clutch assembly, and low sun gear thrustwasher from transmission case.

12) Remove low servo band, strut assembly, low servo piston and piston return spring from transmission case.

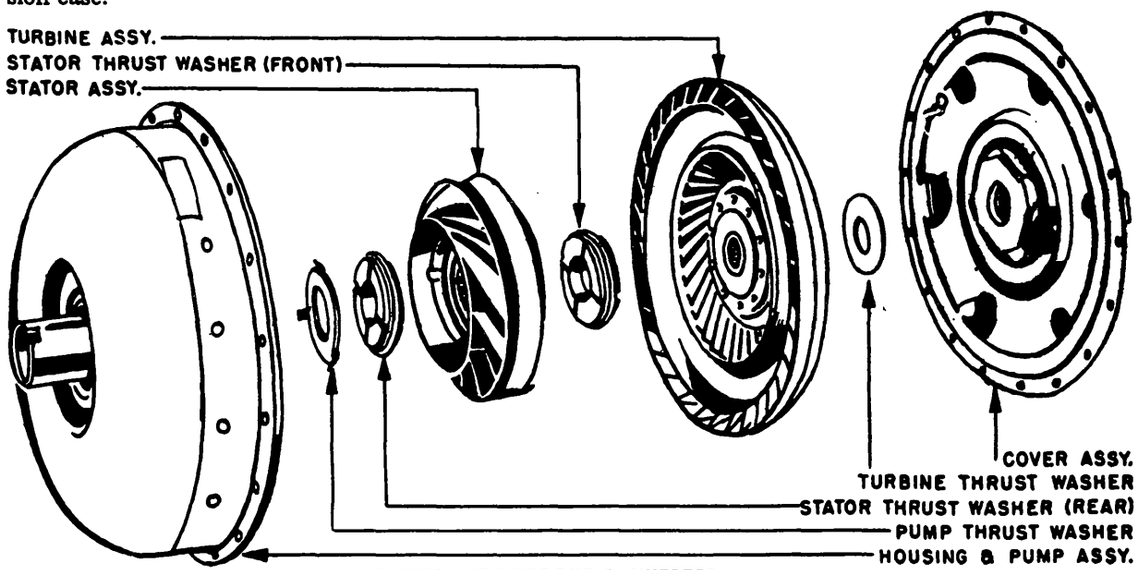
13) Remove speedometer driven gear assembly. Take out universal joint retainer bolt and lockwasher on rear end of output shaft, slide universal joint yoke off end of shaft.

14) Take out attaching bolts and remove governor cover on left side of transmission case, remove gasket. Remove governor assembly (allow governor to turn in clockwise direction while withdrawing it from case).

15) Use tool J-3383 to rotate parking lock pawl spring until end unhooked from case, remove spring and parking lock pawl. Remove parking lock lever and steel washer, parking lock lever shaft assembly, and oil seal from case.

16) Remove transmission oil seal using tool J-5859 and remove transmission assembly and "O" ring seal. Remove speedometer drive gear from output shaft with tool J-5814.

►***CAUTION—Do not attempt to remove planet carrier assembly until transmission rear bearing locating snap rings, retainer and bearing are removed.***



17) Remove the three bearing retainer screws and lockwashers and remove rear bearing retainer. Remove rear bearing locating snap ring from output shaft. Remove rear bearing from output shaft with tool J-5814, then remove bearing locating front snap ring from output shaft.

18) Working from rear of transmission case, position the "O" stamped on face of output shaft at top center. This aligns the drive pin in output shaft with "eyebrow" opening in rear oil pump cover. Planet carrier can now be removed through front of case. Do not lose rear oil pump drive pin.

►***CAUTION—Do not drive on end of output shaft.***

19) Remove reverse drum and thrust washer. Using tool J-4277, loosen reverse servo adjusting screw

CONTINUED ON NEXT PAGE

P WER LIDE TORQUE C NVERTER

POWERGLIDE (Continued)

locknut, back off adjusting screw and remove reverse brake band assembly and reverse servo piston. Remove rear pump attaching bolts and lockwashers and remove rear pump assembly and gasket. Remove lubrication pressure relief valve from transmission case.

►*For DISASSEMBLY of above units, see OVERHAUL data following.*

OVERHAUL

►**"O" RING SEAL CAUTION:** *These seals must be discarded when removed and a new seal installed exactly as directed below.* "O" ring rubber seals are special design and are installed with side clearance in ring groove so that oil pressure on seal deforms the rubber and extrudes a portion of the rubber into the clearance space between the mating parts to provide a positive seal against loss of oil pressure. Seals **must not be re-used.**

"O" Ring Seal Installation—Make certain that parts are clean and that burrs and sharp edges are removed. Seal must be free of any twists (place ring on flat surface and allow it to assume natural position) and **must not be twisted during installation.** Engage one side of ring in groove, pull other side straight back until it can be fitted in groove without twisting. Work ring against trailing edge of groove (last side to enter when parts assembled) using flat tool entered between ring and leading edge of groove to move ring without twisting. Lubricate "O" ring and parts with transmission oil.

CONVERTER OVERHAUL (Unit on bench—after removal from transmission):

Disassembly: 1) Remove all converter cover attaching bolts and locknuts, use small punch to drive out split dowel pin in cover, lift cover off.

2) Remove turbine assembly, stator assembly, stator thrustwashers, and pump thrustwasher. Remove thrustwasher from turbine hub. Remove "O" ring seal from converter cover.

3) Remove front cam retainer ring and remove stator thrust washer. *CAUTION - Use care when separating parts of stator so that cam rollers and springs (8 each) do not become lost.* Remove stator race, cam roller and springs and overrun cam from stator body.

4) Remove rear cam retainer snap ring and remove rear stator thrust washer.

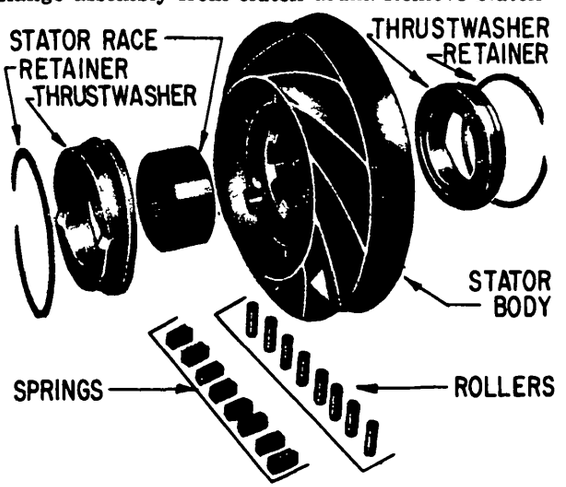
Inspection: Wash all parts in cleaning solvent and dry with air. Inspect converter pump hub, turbine hub, and converter cover bushing for galling, scoring, or excessive wear. Inspect all thrustwashers for galling, scoring, or excessive wear. Check turbine vanes and stator vanes for looseness or damage. Inspect stator race and cam rollers for galling or scoring. Inspect cam springs for distortion. Check spring guides for wear or damage. Inspect over-run cam roller and spring retainer for wear or damage. If bushing in converter cover worn or damaged, install new bushing as follows:

Converter Cover Bushing Replacement: Precision type bushing, No. 3702079, furnished for field installation. Use bushing remover tool J-5381 to remove old bushing from cover. Place new bushing on pilot end of Bushing Replacer Tool J-5382 and press bushing into place in cover using an arbor press. *NOTE—Bushing is finished to size and does not require reaming.*

Reassembly: 1) Place stator body face down on bench and install rear stator thrust washer (front and rear thrust washers are the same), then install retaining snap ring, making sure snap ring is fully seated in groove in stator body. *NOTE - Front of stator can be identified by the word "Front" cast on stator and by the vanes being thicker at front than at rear.*

2) Reverse stator body and key overrun cam to stator body. Assemble cam rollers and springs in overrun cam, then install springs with open ends of springs toward hub. *NOTE - Springs are "zig-zag" flat type, and incorrect assembly can cause excessive wear between springs and race.*

3) Coat stator race and installing tool J-5390 with a light film of oil; then place stator race on pilot end of installing tool and carefully rotate stator over tapered end of tool and stator race. Be careful not to dislodge rollers. Install front stator thrust washer and retain with snap ring. Check operation of stator. Stator should freewheel in clockwise direction when viewed from front.



4) Place converter pump on bench, then install thrust washer to converter pump hub making sure tabs are engages in notches of hub flange. Install stator assembly with front toward converter pump cover.

5) Install thrust washer on turbine hub and assemble turbine assembly to converter pump. Install new "O" ring seal on converter cover, then align blue strip on converter cover with blue strip on converter pump and install converter cover. Install converter pump-to-converter cover attaching bolts and locknuts and tighten to 20-25 ft. lbs.

TRANSMISSION OVERHAUL: *After removal from case, overhaul sub-assemblies or units as follows:*

Planetary Unit Clutch: Place unit on bench with clutch flange upward.

Disassembly—1) Remove clutch flange retainer ring, lift out clutch flange retainer. Remove clutch flange assembly from clutch drum. Remove clutch hub thrustwasher, hub, and all clutch plates from clutch drum.

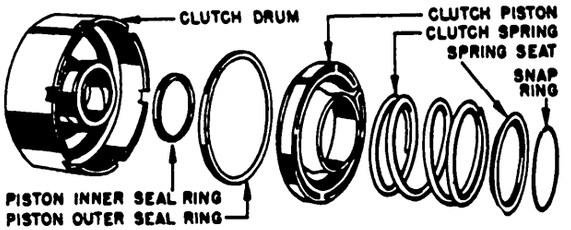
POWERGLIDE STATOR ASSY.

2) Place clutch drum in bench press, install spring compresion tool J-5133 and compress spring enough to remove snap ring, use KMO-410 pliers to remove snap ring. Relieve spring pressure, remove tool, lift out clutch spring seat and spring.

3) Rap clutch drum face down on a wood block to dislodge clutch piston, lift piston out, remove outer seal ring from piston and inner seal ring from clutch drum hub.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect drum brake band surface for scoring or burning, check drum bushing for scoring or excessive wear. See that clutch flange does not have any appreciable play in drum slots. Check all clutch plates for burning or galling, see that composition plates are free fit on clutch hub and that steel plates are free fit in clutch flange. Check low sun gear for nicked or burred teeth. Inspect relief valve steel ball in clutch piston and make certain that ball is free to move in hole and that orifice to rear of piston is open. If necessary, replace ball as follows:

►*RELIEF VALVE CHECK BALL NOTE:* If clutch relief valve check ball in clutch drum is loose enough to come out or too tight to rattle, replace the clutch drum as an assembly. Replacement or restaking of check ball should not be attempted.



Reassembly—1) Install new outer seal ring on clutch piston with lip of seal toward pressure side of piston *(CAUTION*—use care not to stretch seal). Install new inner seal ring on inner hub of clutch drum with lip of seal toward bottom of clutch pocket.

2) Lubricate inner diameter of clutch drum and both seals with transmission oil, carefully install piston in clutch drum using a piece of feeler stock to insure seating of outer seal ring in clutch drum.

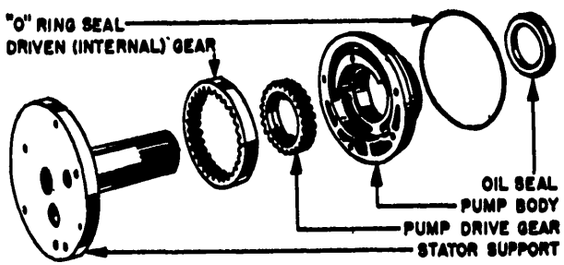
3) Install clutch spring and spring seat, use tool J-5133 in an arbor press to compress spring *(CAUTION*—Make certain spring does not hang up in snap ring groove which would damage spring seat and groove), install snap ring. Release pressure, remove tool.

4) Place clutch hub with thrust washer on clutch flange with open side of clutch up and install five steel and four composition plates alternately. *NOTE - When installing plates, start with a steel plate. 1958 type plates have an "O" stamped on them and this mark must be in same direction on all plates (later type plates or*

CONTINUED ON NEXT PAGE

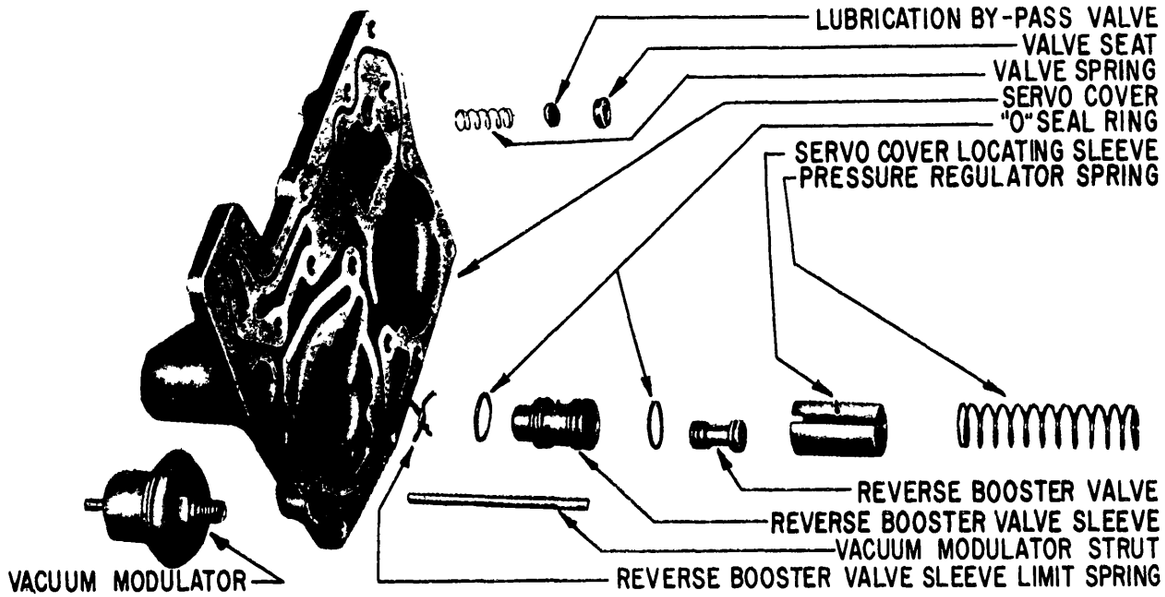
POWERGLIDE CLUTCH PISTON ASSY.

POWERGLIDE (C ntinu d)



rev rsibl and unmarked). It is suggest d that driven plate nesting be verified on bench prior to stacking with drive plates in clutch drum. When clutch driven plates are correctly stacked, wave pattern on face will permit plates to nest tightly. If incorrectly stacked, intermittent openings will be visible between adjacent plates.

5) Check endplay using a feeler gauge inserted between clutch flange drive lug and drive slot in drum. This endplay must not exceed .013". Adjust by installing retainer ring of correct thickness to provide correct endplay. ***NOTE*****—Retainer ring furnished .055", .064", .073" thick.**



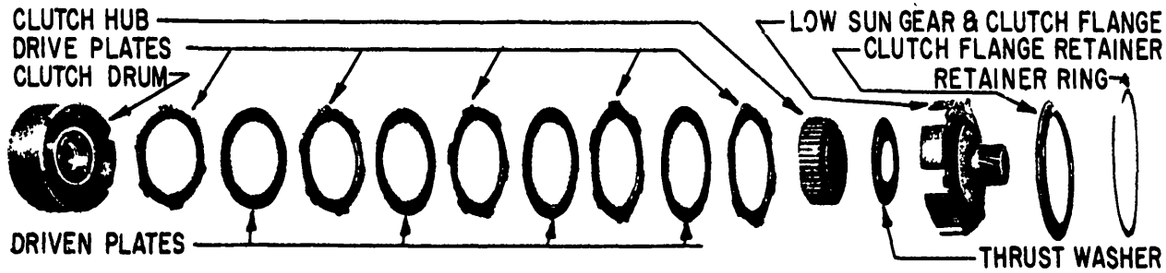
Servo Cover: Disassembly - Remove pressure regulator reverse booster valve only.

Inspection—Inspect cover for nicks or cracks. Using a small punch or similar tool, and working through the opening in the by-pass disc seat, exert pressure on the disc to make sure disc and spring are free and that disc is seating properly *(NOTE*—Do not remove disc seat unless there is evidence of damage). Inspect pressure regulator reverse booster valve springs for distortion or damage. Inspect pressure regulator reverse booster valve for galling or scoring and make sure it operates freely in bore in guide. Inspect snap ring for loose fit in groove. Inspect bore in valve guide for galling or scoring and check seal for distortion or damage. Check valve guide bore in servo cover for roughness or burrs and make sure that valve spring and guide spring and seat will seat properly in bottom of bore.

Reverse Booster Valve & Sleeve Replacement - If inspection indicates that valve is not free in valve sleeve and cannot be corrected by using a new valve, replace valve sleeve as follows: If valve is stuck tight in valve sleeve, apply air pressure to modulator passage (sleeve may be blown out with valve). To remove sleeve, form a hook end on a piece of 3/32" rod and insert hook into feed hole in large diameter bore. *NOTE - This operation will damage sleeve and sleeve should not be reused.* Use a pair of needle nose pliers and remove booster sleeve limit spring. *NOTE - This spring should not be reused.* Place new limit spring in bottom of servo cover bore with wide tabs seating on bottom of bore. Install "O" rings on new booster valve sleeve and push into bore so that end of sleeve is 0.4" (13/32") below finished face of servo cover. *CAUTION - Do not push sleeve in beyond the above dimension.* Install reverse booster valve.

POWERGLIDE FR NT IL PUMP

SERVO COVER ASSEMBLY



Lubrication By-Pass Valve Assembly Replacement—If during inspection it is evident that the lubrication by-pass valve assembly is not functioning properly, correct as follows: Using a suitable tool remove the nylon by-pass disc seat, then remove disc and spring. Inspect disc for burrs, and spring for distortion. Inspect wall of by-pass valve cavity for roughness, nicks or burrs. Insert by-pass disc in its cavity to make sure its movement is not restricted. Remove disc from cavity. Replace any part that is defective. Install by-pass spring in its cavity in servo cover and install by-pass disc. With servo cover inner surface facing upward, position a new disc seat over its opening in cavity and press into place using a socket of proper size. It should be flush to .005" below inner surface of servo cover. ***CAUTION—Under no circumstances should the by-pass disc seat that was removed be re-installed.***

Reassembly - Place new limit spring in servo cover bore with wide tabs seating on bottom of bore. Install "O" rings on booster valve sleeve and install in bore so that end of sleeve is 13/32" (.40625") below face of servo cover (19/32" on transmissions with pressure regulator dampner). Install reverse booster valve, then install servo cover locating sleeve in bore of cover until it just contacts booster valve sleeve. *CAUTION - Do not exert any downward force on reverse booster valve sleeve.* Install pressure regulator valve, damper valve assembly and spring, then install reverse servo spring. Use guide pins to assemble servo cover to transmission case. *CAUTION - Mak sure locating sleeve is in alignment with pressure regulator valve bore.* Check alignment of vacuum modulator hole in servo cover with hole in case.

Front Pump: Disassembly—Slide stator support out of pump body, lift out pump gears (CAUTION—use extreme care not to drop or nick gears), remove and discard "O" ring seal.

Inspection—Wash all parts in cleaning solvent and dry with air. Inspect pump gears for wear, nicks, or other damage. Inspect pump body and pump face of stator support for nicks and scoring. Inspect pump body oil seal for excessive wear, damage, or evidence of leaking (see Oil Seal Replacement below). Inspect pump body bushing for gall-

CONTINUED ON NEXT PA E

P WERGLIDE MULTIPLE DISC CLUTCH

POWERGLIDE (C ntinued)

ing or scoring, check bushing wear or clearance as directed below. Check pump gear clearances as follows:

1) Pump Gear Cl arances - Install clean dry gears in pump body, check clearances with feeler gauge.

Driv n Gear Clearance - .0035-.0065" clearance between outer diameter of gear and pump body. .003-.009" clearance between inner diameter and crescent.

G ar End Cl arance - Place scale across face of pump body, measure clearance between scale and face of gears. This clearance should be .0005-.0015".

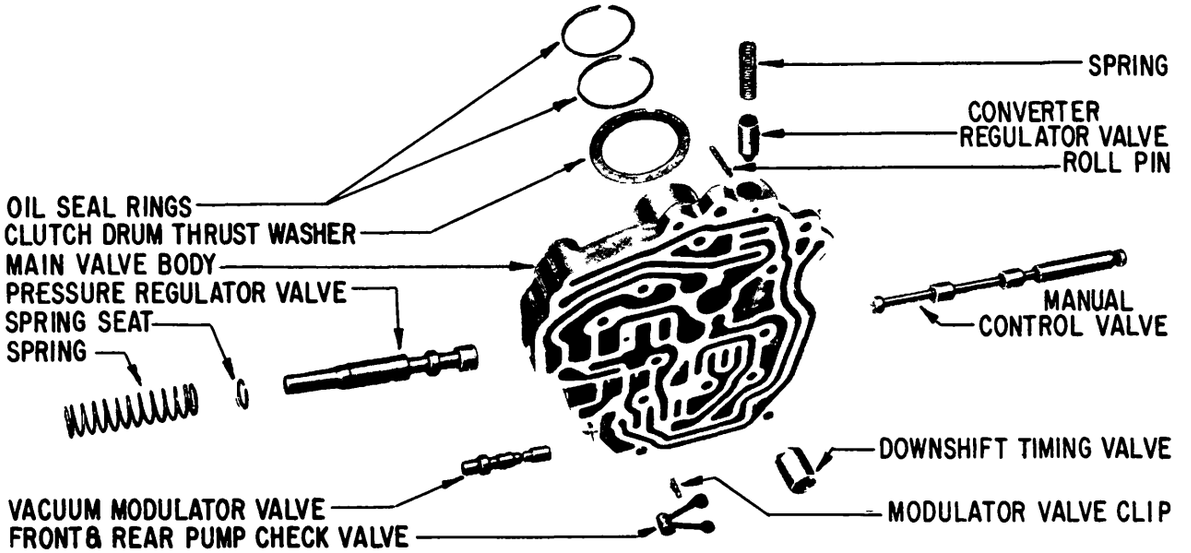
2) Pump Body Bushing - Temporarily install pump body on converter pump hub, measure bushing-to-hub clearance with a feeler gauge. This clearance should be .0005-.0015".

3) Oil Seal R plac m nt (Transmission Disassembled) - Pry out old seal and install a new one using Tool J-6839.

Transmission Not Disassembled - Seal can be replaced without disassembling transmission as follows: With converter removed, screw Tool J-6793 into bore of old seal and pull seal by driving it out with a slide hammer. Lightly hone any burrs in front pump bore, then position replacement front seal in bore, and drive seal into place with Tool J-6839. *NOTE - Outer diameter of s al should be coat d with non-hardening sealer before installation.*

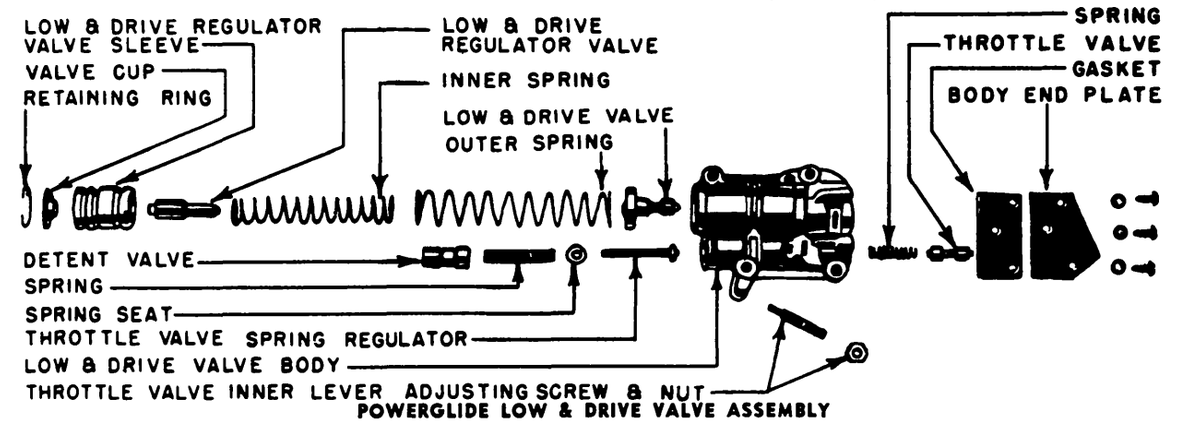
R ass mbly - Install new "O" ring seal in pump body. Remove gears from pump body, oil thoroughly with automatic transmission oil and install in pump body. Assemble stator support through drive gear, aligning attaching holes.

Rear Pump: Disassembly—Take out two screws and remove pump body plate, lift out pump gears.



Inspecti n—Wash all parts in cleaning solvent, blow out all oil delivery holes, dry with air. Inspect pump body for nicks and scoring, inspect gears for wear, nicks, or other damage. Check gear clearances (clearances are same as for front pump—see Pump Gear Clearances above). Inspect rear bearing for roughness but do not remove bearing unless replacement required (see Bearing Installation below).

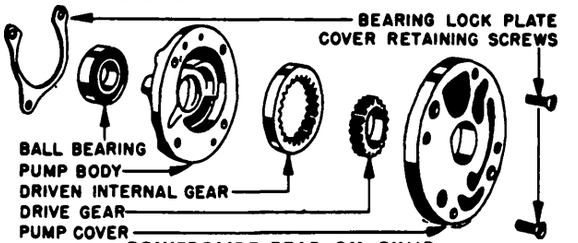
Pump Bearing Replacement—Remove tnree retaining capscrews, lockwashers, and lockplate. Drive old bearing out. Press new bearing in place, install lockplate and retaining screws and lockwashers, tighten screws securely.



Reassembly—Oil pump gears thoroughly with transmission oil and install in pump body. Install pump body plate and two slotted attaching screws, tighten screws to 3½-5 ft.lbs. torque.

Valve Body: ***CAUTION—Handle all valves with care to avoid damage, keep valve and spring assemblies separate to avoid confusing or interchanging parts.***

Disassembly - Use needle nose pliers and remove hairpin retainer from vacuum modulator valve, then remove valve from body. Place valve body face down on two blocks of equal thickness, and with a small pin punch drive out converter pressure regulator valve retaining pin and remove spring and valve from bore. Remove two clutch drum oil seal rings from oil delivery sleeve, then remove front and rear oil pump check valve from valve body. *NOTE - Downshift timing valve must not be removed unless replacement is necessary as indicated by poor coast downshift.* Remove manual control valve.



POWERGLIDE CONTROL VALVE ASSEMBLY (TYPICAL)

POWERGLIDE LOW & DRIVE VALVE ASSEMBLY

Inspection - Wash all parts in clean solvent and blow dry with air (blow out all passages). *CAUTION - Do not use rags to dry parts. Also, be sure that drilling immediately below vacuum modulator valve is plugged with a stamped metal plug.* Inspect all valves for nicks, scores, burrs or galling and make sure that all valves move freely in their respective bores. Check converter regulator valve spring for distortion or damage. Check oil seal rings for nicks or burrs and make sure they are free in ring grooves. Also, install rings in clutch drum bore and make sure hooked ring ends have clearance.

POWERGLIDE REAR OIL PUMP

Downshift Timing Valve Replacement - Pry out old valve assembly with a small pin punch using care not to damage bore in valve body. Using an arbor press and a 7/16" socket, press new downshift timing valve into valve body until tip on check ball end of valve assembly is flush to .015" below surface of valve body.

CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinued)

R assembly - Place valve body face down on wood blocks, then assemble converter pressure regulator valve spring in valve and then, as an assembly, install in valve body bore. Install retaining pin. Install manual valve, then install vacuum modulator valve and attach retaining clip on valve groove. Install spring clip on pressure regulator valve and insert valve into bore in valve body. Install front and rear oil pump check valve in valve body making sure it is flush with or below valve body face. Install the two clutch drum oil seal rings in ring grooves in oil delivery sleeve. *NOTE - Interlocking type cast iron rings are used. These rings are removed and installed in their grooves by applying pressure to the ring with index finger and thumb. One end of ring must be pressed into ring groove while other end is pushed out away from groove to lock or unlock ring.*

Low & Drive Valve Body: *CAUTION - Do not disturb throttle valve adjustments (two adjusting screws-one in boss on valve body and one in throttle valve inner lever) unless required by installation of new parts. THROTTLE VALVE MUST BE ADJUSTED IF THESE SETTINGS DISTURBED (see "Throttle Valve Inner Lever Adjustment").*

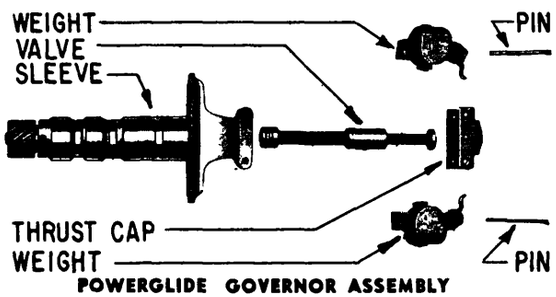
Disassembly - 1) Remove attaching bolts, then hold low and drive valve body in one hand and with a soft hammer tap on inner side of cover until it is free of locating pins. *CAUTION - Exert pressure on detent valve when separating valve body from cover to prevent loss or damage of parts from falling.*

2) Remove detent valve, spring, spring seat and throttle valve spring regulator assembly. Remove throttle valve retainer clip, then remove throttle valve and spring. Use special snap ring pliers, Tool J-5403, and remove low and drive regulator cap retainer, then remove low and drive regulator valve cap, sleeve and valve as an assembly. Remove low and drive valve inner and outer springs, and low and drive valve.

3) Remove low and drive body end plate screws and lockwashers and remove body end plate and gasket. Remove throttle valve control outer lever assembly. Remove throttle valve lever shaft shield and throttle valve inner lever assembly. Remove throttle valve lever shaft seal from counterbore in cover.

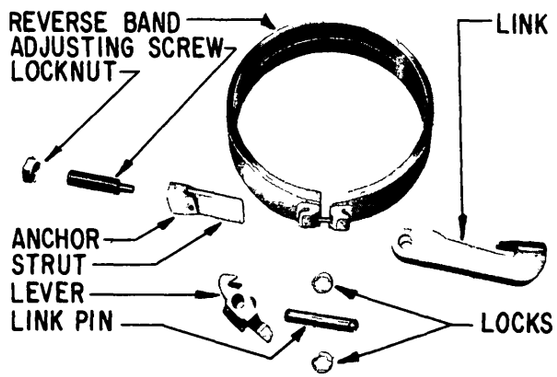
Inspection - Wash all parts in cleaning solvent and blow out all passages with air. Inspect all parts for burrs, scoring, or nicks and make sure that all valves move freely in their bores. Check throttle valve spring regulator assembly for free operation in opening of detent valve. Inspect detent valve spring and throttle valve spring for distortion or damage. Inspect low and drive valve inner and outer springs for distortion or damage. Inspect throttle valve inner lever assembly shaft for scoring or galling and the lever for being tight on shaft. Check throttle valve inner lever assembly shaft for free operation in its bore in side cover. Inspect detent valve stop in side cover for distortion or or damage (replace with new stop if necessary). Inspect locating pins in valve body and side cover for distortion or damage and replace with new pins if necessary. *NOTE - One locating pin should be in valve body and the other in the side cover.* Inspect mating surfaces of valve body and side cover, making sure they are free of nicks and burrs.

Reassembly - 1) Install low and drive valve in valve body bore. *CAUTION - This valve must be guided into its bore in valve body to prevent damage to bore as follows: Insert a piece of brake tubing into valve shank bore in rear of valve body, engaging the tit on end of shank in opening in tubing, then slowly move valve into its proper position.* Install low and drive regulator inner and outer springs in valve bore. Assemble low and drive regulator valve and cap to low and drive regulator valve sleeve, then install as an assembly in valve body bore. Be sure inner spring is properly seated on seat of low and drive regulator sleeve. Compress low and drive valve assembly into body bore and install retainer, using special snap ring pliers, Tool J-5403. Be sure retainer is properly seated in its groove in valve body bore.



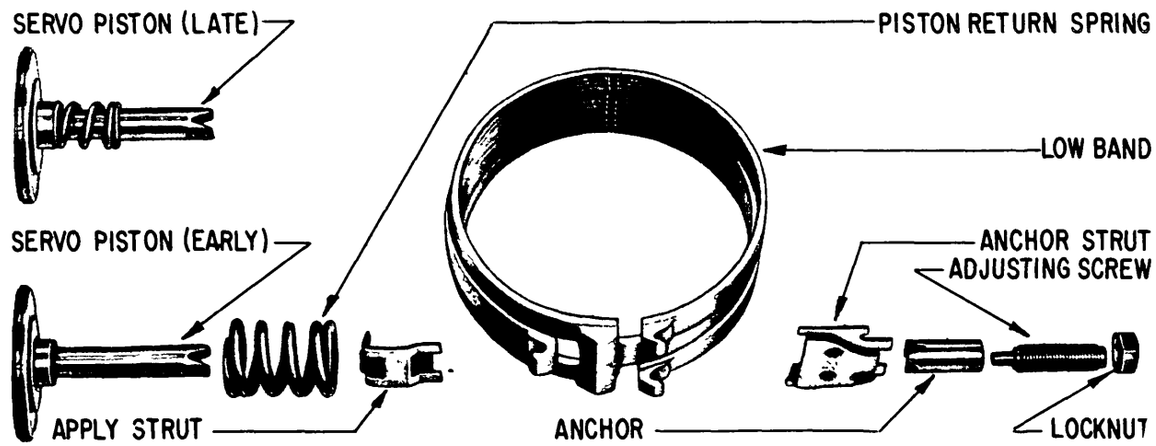
2) Install throttle valve spring and valve in valve body bore, then install throttle valve clip. Place low and drive body end plate and gasket in position and tighten attaching screws to 1½-2½ ft. lbs.

3) Install throttle valve spring regulator assembly in valve body bore, making sure it is seated on throttle valve spring. Install detent valve spring seat in valve body bore, threading the spring of throttle valve spring regulator assembly through the opening in detent valve.



4) Place side cover in vise with face up. Align locating pin hole in low and drive valve body assembly and locating pin in side cover. Exert pressure on valve body to keep locating pin in locating hole, at sametime compress detent valve into valve body bore. Rotate valve body counterclockwise until locating pin in valve body enters locating hole in side cover. *CAUTION - Be sure that face of detent valve is r sting against d t nt valve stop pin in side cover.*

5) Tighten low and drive body attaching bolts to 3½-5 lbs. Install throttle valve inner lever assembly to side cover. Install new seal over shaft and into counterbore in cover, then install shield. Install throttle valve control outer lever assembly on inner lever shaft.



CONTINUED ON NEXT PAGE

POWERGLIDE GOVERNOR ASSEMBLY

POWERGLIDE REVERSE BAND ASSEMBLY

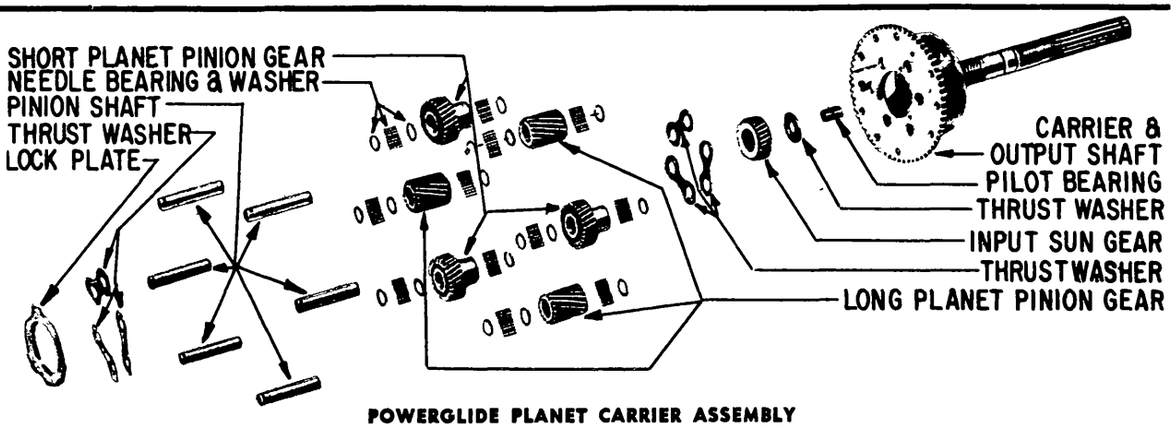
POWERGLIDE LOW BAND & SERVO PISTON ASSEMBLY

POWERGLIDE (C ntinued)

From underside, install outer lever attaching bolt and tighten securely.

Throttle Valve Inner Lever Adjustment: Rotate throttle valve inner lever until it just contacts face of the detent valve. Hold lever in this position and turn adjusting screw until it just contacts flat surface of the step in the lever. Back off one complete turn and lock in this position by tightening adjusting screw lock nut securely.

Gov rnor: *CAUTION - Th nly parts available for servic r plac ment or th governor assembly (complete), and driven gear. Gov rnor should not require disass mbly xc pt for cleaning and removal of foreign mat rial causing improper operation. See "Governor Driv n Gear R plac ment" below for disassembly and reass mbly.*



Gov rnor Driven Gear Replacement - A unit package containing a governor driven gear and pin, and two governor weight pins is available for service replacement. *NOTE - Th nylon g vernor gear used on current production and for s rvice replacement is interchangeabl with any nyl n gear on previous models. DO NOT us a brass gear to replac nylon gear.*

Installation—Cut off ends of governor weight pins and remove weights and governor valve. *(NOTE*—Carefully protect governor valve to prevent damage. Weights are interchangeable from side to side). Drive out governor gear retainer split pin using a small punch. Support governor on 3/16" plates installed in exhaust slots of governor sleeve, place in arbor press and with a long punch, press gear out of sleeve. Carefully clean governor sleeve of chips and reinstall in arbor press. Position new gear in sleeve and with a suitable socket, press gear into sleeve until nearly seated. Then remove any chips that may have shaved off the.gear hub and press gear in until it bottoms on shoulder. *(CAUTION—It is important that a socket be used to prevent damage to thrust button on end of gear).* Drill a new hole through sleeve and gear locating it 90° from existing hole, using a No. 24 (.152") drill. Install split pin retainer. Wash governor assembly thoroughly. Install governor valve and make sure that it operates freely. Install governor valve in bore of governor sleeve. Align governor weight pin holes in the governor thrust cap, governor weight assemblies and governor sleeve and install new pins. Crimp both pins to prevent them becoming dislodged. Check governor weight assemblies for free operation on pins. Check valve opening at entry and exhaust which should be .020" minimum. Adjust by bending tangs on governor weights.

R vers Serv Piston (1958-60): Remove reverse servo piston ring from piston and install in reverse piston bore. Check ring gap which should be .005-.010". Reassemble reverse servo piston ring on piston.

L w Serv Piston (Early 1958 - With Shaft Pressed Into Head): Cannot be disassembled. Check in same manner as for reverse piston (above).

L w Serv Pist n (Late 1958-60 - With Shaft R tain d in Head With Pin): Place low servo piston in an arbor press and support notched end of piston rod on a wood block. Use Tool J-3377 and compress piston spring and remove rod retainer. *CAUTION - This cushion spring is under 150 lbs. pressure.* Remove piston spring and washer from piston rod. Check ring gap which should be .005-.010". Assemble piston ring to piston and insert feeler gauge between side of ring and one wall of piston groove. Ring clearance should be .0005-.005". Assemble washer, spring and piston on piston rod, then place assemble in an arbor press and compress spring with Tool J-3377. Install retainer, making sure it is properly seated in piston rod groove.

POWERGLIDE PLANET CARRIER ASSEMBLY

Planet Carrier Assembly: ***Should not be disassembled unless inspection below indicates overhaul required. See Planet Carrier Overhaul below.***

Inspection—Wash in cleaning solvent, blow out all passages, dry with air. Inspect all gear teeth for nicks, scoring, or other damage. Check end clearance of planetary pinions with feeler gauge inserted between ends of pinion and thrustwasher. This clearance should be .006-.030". Check reverse sun gear rear thrustwasher for wear or damage. Inspect drum bushing for wear, scoring, or damage; inspect outer diameter of drum for scoring or burning. Check output shaft bearing surfaces for wear, nicks, or scoring. Check input pilot bushing for wear or scoring.

Planet Carrier Overhaul: If inspection (above indicates) that parts require replacement, proceed as follows:

Disassembly - Place assembly in holding fixture or clamp in a vise with front end upward. Mark each pinion and also mark planet carrier (use prick punch or other scribing tool) so that shafts can be replaced in the same location. *NOTE - Pinion shafts are no longer a selective fit, nowever, it is very important that pinion shafts be replaced in the same locations from which they were removed.*

1) Remove pinion shaft lockplate screws and rotate lockplate counterclockwise to remove it. Starting with a short planet pinion, and using a soft steel drift, drive out lower end of pinion shaft until pinion shaft is raised above pressed fit area of output shaft flange. Insert Tool J-4599 into short planet pinion from lower end and push planet pinion shaft ahead of it until tool centered in pinion and pinion shaft is removed from carrier. *NOTE - To l J-4599 comes in two pi ces, both alik . Only one piec is us d for removal, and two are used for reassembly.* Remove Tool J-4599, needle bearings, and three spacers from pinion. *CAUTION - Use care to prevent loss of needle bearings. Twenty bearings are used in each end and are separated by a bearing spacer in the center.* Follow above procedure and remove adjacent long pinion (paired to short pinion by thrust washers), then remove upper and lower thrust washers.

2) Remove and disassemble remaining planet pinions, in pairs, by first removing a short pinion, then the adjacent long pinion. Remove input sun gear and input sun gear thrust washer.

Inspection - Wash all parts in clean solvent and blow dry with air. Inspect all pinion gears and reverse sun gear for nicked or damaged teeth, inspect all thrust washers for wear, nicks, or scores. Inspect needle bearings for wear. Replace all worn or damaged parts. *NOTE - Needle bearings must be replaced in complete sets.*

Reassembly - *CAUTION - Pinion shafts must be replaced in accordance with marks made at disassembly (shaft is not a selective fit but should be replaced in same bore in carrier).* Assemble and install as follows:

1) Install Tool J-4599 in one long planet pinion, assemble needle bearing spacer and needle bearings in pinion (20 at each end) using cup grease to hold needle bearings in position.

2) Install pinion assembly in planet carrier with tool centered in assembly and with thrust washer (oil grooves in thrust washer toward gears) at each end of pinion. *NOTE - Long pinions are located opposite closed portion of carrier, short pinions are located opposite carrier openings.* Feed second part of Tool J-4599 in from top of planet carrier, making certain tool picks up thrust washer, and push first part of tool down and out of lower end. *NOTE - Tool must pick up second thrust washer as it is pushed down.* Lubricate correct pinion shaft (as marked at disassembly) and install it from top, pushing the assembly tools out ahead of it. Turn shaft so that slot in upper end faces toward center

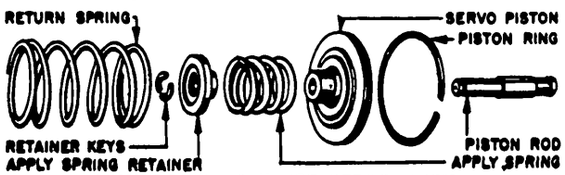
CONTINUED ON NEXT PAGE

POWERGLIDE (C ntinu d)

of assembly, then tap shaft down with a brass or soft steel drift until lower end is flush with lower face of carrier.

3) Assemble and install adjacent short planet pinion (paired with the above long planet pinion by using same thrust washers) by repeating procedures for long pinion (above). Install input sun gear thrust washer and input sun gear.

4) Assemble and install remaining planet pinions, in pairs, by first installing the long planet pinion and then the adjacent short planet pinion.



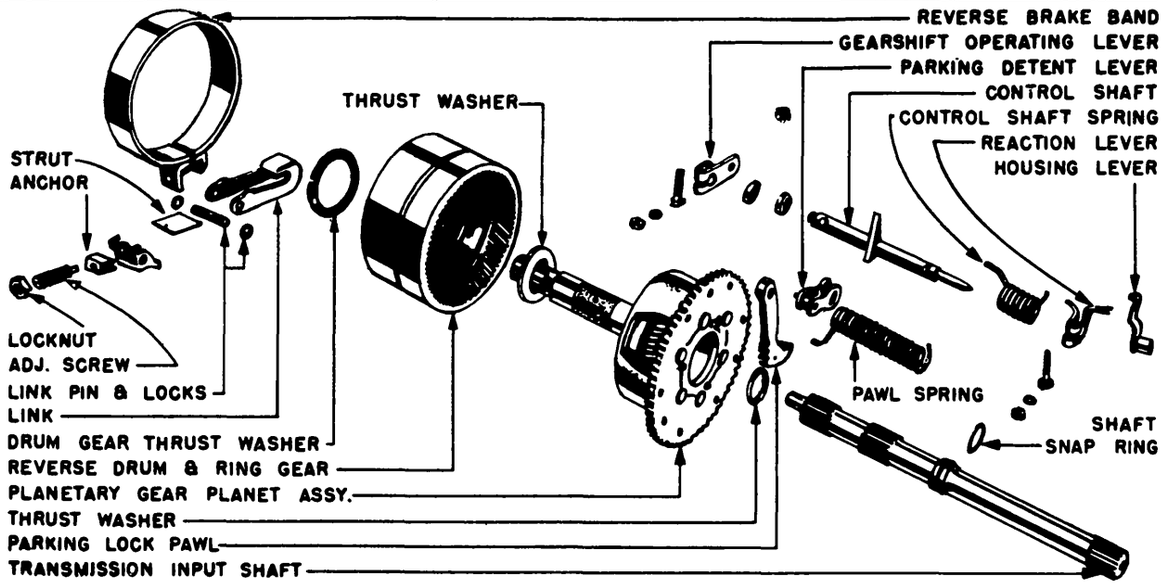
5) Check endplay of planet pinions using a feeler gauge inserted between end of pinion and thrust washer. This clearance should be .006-.030". Place pinion shaft lock plates in position, then with the extended portions of lock plate aligned with slots in planet pinion shafts, rotate lock plate clockwise until attaching screw holes are accessible. Install attaching screws and tighten to 2½-3 ft. lbs.

Input Shaft: Inspect shaft splines for nicks, wear, or other damage. Check spline fit in clutch hub, reverse sun gear, and converter hub. Inspect oil seal ring for wear and free fit in groove. Inspect input shaft pilot roller bearing installed in base of output shaft and if worn or damaged, pry out. Install new bearing by pressing in with pilot end of input shaft as a press tool.

Transmission Case & Rear Bushing: Check case for cracks, inspect rear bushing for wear or damage and replace if necessary.

Bushing Replacement—Place transmission case in an arbor press with rear end up. Using a cape chisel, cut bushing and remove from bore in case. Install rear bearing in its bore in rear oil pump assembly and install rear oil pump in case to serve as a pilot when installing new bushing. Place transmission case in an arbor press with front end up. Place new bushing on bushing installer J-4276, with the square end of bushing against shoulder of installer. Insert in case, entering pilot of tool into rear bearing, and press bushing into place. Bushing is precision type and does not require reaming.

Low & Reverse Brake Bands: Inspect bands for wear, cracks, and scored or burnt lining. Lining is bonded to band. Inspect linkage for wear.



POWERGLIDE REVERSE SERVO ASSY.

REASSEMBLY

AFTER ALL MAJOR UNITS REASSEMBLED (See Overhaul above), install units as directed below using ALL NEW GASKETS AND SEALS and tightening all parts evenly to SPECIFIED TORQUES.

CONVERTER HOUSING ASSEMBLY: *Install units:*

Valve Body: First install suction screen in oil sump *(CAUTION*—screen must be thoroughly cleaned), see that sealing ring is in place. Install two ¼—20 x 3½" guide pins (part of Pilot Stud Set J-3387) in two valve body attaching bolt holes, place new valve body gasket in position over guide pins, install valve body assembly. Install all attaching bolts *(CAUTION*—lower left bolt over accumulator bore is special self-locking type and must be installed in this position), tighten all bolts evenly in a criss-cross pattern to 7½-10 ft.lbs. torque. Check manual valve and pressure regulator valve for free operation after all bolts tightened.

POWERGLIDE PLANET CARRIER, REVERSE BAND, & PARKING LOCK

Front Pump: Align holes in stator support with mounting holes in pump body. Install two ¼—20 x 3½" guide pins (part of Pilot Stud Set J-3387) in pump mounting holes, use Driver J-4263-5 to install pump in converter housing *(CAUTION*—line up suction and oil delivery holes on left side of pump). Install five self-locking bolts through valve body and into pump, tighten all bolts evenly to 7½-10 ft.lbs. torque. *CAUTION—Check pressure regulator valve for free operation after bolts tightened and make certain that pump operates freely.*

Low & Drive Valve Body: Install two 5/16" - 18 x 3" guide pins (part of Pilot Stud Set J-3387) in two valve body mounting bolt holes on left side of converter housing, place new gasket in position over guide pins, install valve body assembly. Install attaching bolts and lockwashers, tighten bolts evenly to 15-18½ ft. lbs.

TRANSMISSION CASE ASSEMBLY: Install units:

►*REAR PUMP-TO-CASE ATTACHING BOLT PRODUCTION CHANGE:* A new "hollow" bolt is used in later cars to replace the top rear pump-to-case attaching bolt. This bolt provides a vent which allows a more accurate dipstick reading when oil is added to transmission.

Rear Pump: Install two 5/16—18 x 3" guide pins (part of Pilot Stud Set J-3387) in pump attaching bolt holes, place new gasket in position over guide pins, install pump *(CAUTION*—align oil suction and delivery holes), tighten pump mounting bolts evenly to 12½-15 ft.lbs. torque.

Lubrication Pressure Relief Valve: Make certain that valve is clean and openings free from obstructions, see that valve disc and spring operate freely. Install relief valve in mounting hole in rear of transmission case and tighten securely.

Reverse Servo Piston, Band, & Drum: Compress piston ring with Ring Compressor J-3365, install servo piston in case with notch in shaft toward front of case. Install reverse brake band and strut assembly with thin end of band away from piston, thread adjusting screw in until it indexes with hole in anchor. Install bronze thrustwasher on reverse drum hub, install drum in case and into brake band. ***DO NOT adjust band at this point.***

Planet Carrier Assembly: Rotate rear pump drive slot to top of pump, then fill drive pin hole in output shaft with cup grease and install drive pin. *CAUTION - Make sure drive pin does not fall out of shaft during assembly.* Install planet carrier assembly, including steel thrust washer, on shaft in drum, positioning the "O" stamped on face of output shaft of planet carrier assembly at top center. Install rear bearing locating front snap ring in its groove in output shaft and install rear bearing using Tool J-5814. *NOTE - Groove in outer diameter of rear bearing should be to rear of transmission.* Install rear bearing retainer in groove in outer diameter of rear bearing and attach to rear oil pump with screws and lockwashers. Tighten screws to 9-11 ft. lbs. Install rear bearing rear locating snap ring in its groove in output shaft, then use Tool J-5814 and install speedometer drive gear on output shaft. Center raised ground surface of output shaft so that it will mesh properly with speedometer driven gear fitting. Assemble driven gear in fitting, then install as an assembly in bore of

CONTINUED ON NEXT PA E

POWERGLIDE (C ntinu d)

extension Install retainer, attaching screw and lockwasher and tighten to 3½-5 ft lbs

Reverse Band Adjustm nt: *Adjust band at this point. See BAND ADJUSTMENT.*

Transmissi n Endplay Ch ck & Adjustment: After planet carrier assembly installed in case, the correct thickness of clutch drum thrust washer must be determined for correct transmission endplay of 025- 050"

►*GAUGING PROCEDURE CHANGE & TOOL J-4260 RFWORK (To provid a more accurate measurement)* The gauging procedure indicated below, supersedes procedure previously released Tool J-4260 must be reworked as follows in order to use the later procedure for gauging Press low sun gear pilot pins from tool bar, then remove spring and spring retainer from gauge rod Install a steel ball (similar to Rochester Carburetor pump outlet check ball) under end of gauge rod setscrew in tool bar Make a gauging collar (use a 2" length of a six cylinder engine valve guide, and solder a flat washer on one end to provide a larger surface for gauging, then thread a thumb screw through side of guide to permit locking on gauge rod) Slide gauge collar onto gauge rod between tool bar and knurled end of rod

Ch cking & Adjusting - Hold bar of Tool J-4260 solidly across front face of transmission case and push gauge rod into firm contact with front face of input sun gear Tighten setscrew in tool bar to lock gauge rod Slide gauging collar down rod until it seats on tool bar, then securely tighten thumb screw against rod Remove tool with setting retained *NOTF - The above tool setting was obtain d without the low sun gear thrust washer positioned against input sun gear* Place transmission main valve body assembly on a sheet of glass or a smooth table top, then install a clutch drum thrust washer on valve body and lower clutch assembly into place Center the low sun gear thrust washer on top of low sun gear *NOTE - If low sun gear thrust washer is "flanged" type, insert washer flange in I D of low sun gear* Using Tool J-4260, preset at dimension obtained (see above), place tool on top of low sun gear thrust washer, with gauge rod down through center of clutch and valve body so rod end rests on top of table (or glass) Loosen setscrew in tool bar and allow bar to drop down onto low sun gear thrust washer Using a feeler gauge, measure clearance betweer top side of bar and bottom face of gauging collar This dimension represents clearance in transmission and should be 025"- 050" If clearance is not within limits, substitute a thicker or thinner clutch drum thrust washer as necessary Clutch drum thrust washers aré available in three thicknesses as follows 078", stamped "2" (Part No 3737902), 106", stamped "3" (Part No 3737903), 134", stamped "4" (Part No 3737904) *NOTE - After checking and adjustment is completed, remove clutch assembly and thrust washer from oil delivery sleeve*

Parking Lock Mechanism: Install parking lock lever shaft assembly in case, install seal over end of parking lock lever shaft and into counterbore in case with seal lip toward inside of case Install flat washer and parking lock lever on end of parking lock lever shaft, pushing lever onto shaft to obtain 000- 010" clearance between lever and washer Connect short manual shift rod to parking lock lever Tighten clamp screw to 5-7 ft lbs Install parking lock pawl over pawl support rod and install parking lock pawl spring Wind up pawl spring using Tool J-3383, so that spring catches on inside of case

►*1958 INPUT SHAFT PRODUCTION CHANGE* A new low sun gear thrust washer, having no internal splines is used on later transmissions (beginning with Transmission Serial No C-407-D) The new thrust washer is used in conjunction with a new sun gear bushing added to input shaft Assembly procedures are different for the two types as follows

Input Shaft & Clutch Assembly: First Type - Install input shaft to clutch unit, then install thrust washer and locating snap ring on shaft Install unit assembly into case, indexing input shaft pilot with pilot in output shaft and low sun gear with short pinions in planet carrier

Later Type - Install input shaft to clutch unit, then install low sun gear bushing on input shaft spline, bottoming bushing against shoulder on shaft *NOTF - Wire type snap ring, used on input shaft with early type splined thrust washer, is not used on this later design* Assemble low sun gear thrust washer into planet carrier by tilting washer slightly to permit flange of washer to enter behind short planet pinions *NOTE - Use petroleum jelly to hold washer in place* Install clutch and input shaft assembly into case, aligning thrust washer on input shaft and indexing sun gear with short pinions in planet carrier

►*1958 LOW SERVO PISTON ASSEMBLY PRODUCTION CHANGE Two different piston assemblies have been used in production See production change above*

Low Servo Piston & Band Assembly: Install release spring on servo piston rod, use Ring Compressor J.3365 to compress piston ring and install assembly in transmission case. Install low brake band over the drum Install apply strut guide spring over piston rod, engage apply strut in piston rod slot and engage opposite end of strut in the band. Engage anchor strut assembly in band groove and locate opposite end of anchor over the adjusting screw. ***DO NOT adjust the band at this point.***

Governor: Install governor assembly in bore in transmission case *CAUTION - Governor must be allowed to rotate counterclockwise as gear teeth mesh, and care must be taken to prevent damage to teeth* Install two 5/16" - 18 x 3" guide pins (part of Pilot Set J-3387) in governor cover mounting holes, then place new gasket in position over guide pins and install governor cover, attaching bolts and lockwashers Tighten bolts evenly to 9-11 ft lbs

Extension Housing: Position new "O" ring seal on transmission extension Then carefully install extension on transmission case Install attaching capscrews and lockwashers and tighten to 12-15 ft lbs Install transmission extension oil seal using tool J-5154

TRANSMISSION & CONVERTER HOUSING ASSEMBLY:

1) Install manual valve in valve body and manual valve inner lever in converter housing Index lever pin with pickup slot in valve, set manual valve so it projects 1 11/16" out from face of valve body This places valve in "Low" position

2) Install new valve body-to-transmission case gasket, then raise transmission manual lever to top detent position (this is "Low" position and will align reaction lever so it indexes with manual valve inner lever in converter housing)

3) Place clutch drum thrust washer (selective washer of proper thickness as determined when transmission endplay checked above) over oil delivery sleeve Install two 3/8" - 16 x 3¾" guide pins (part of Pilot Stud Set J-3387) in converter housing, then push converter housing and case together, checking to see that reaction lever indexes with manual valve inner lever Install case-to-housing bolts and lockwashers and tighten t- 29-37½ ft lbs From front of converter housing install special self--locking bolt and tighten to 29-37½ ft lbs

4) Install two 5/16" - 18 x 3" guide pins (part of Pilot Stud Set J-3387) as guides for servo cover and install new servo cover gasket

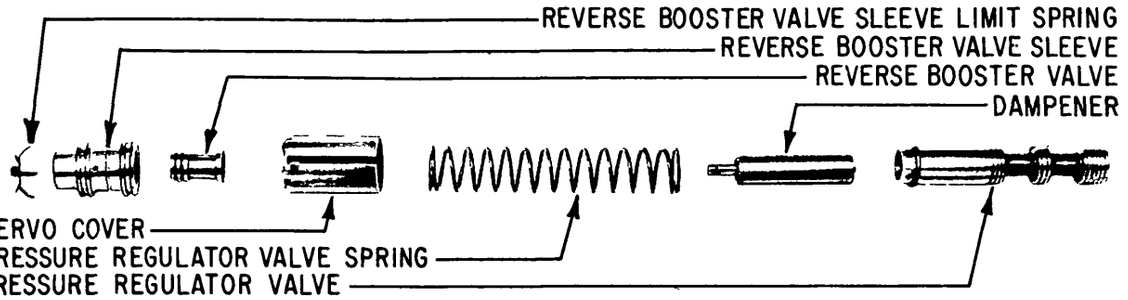
5) Install servo cover locating sleeve in bore of servo cover *CAUTION - Be careful not to exert any downward force on reverse booster valve sleeve*

►*1958 PRESSURE REGULATOR VALVE ASSEMBLY PRODUCTION CHANGE· Beginning with Transmission Serial No C-630-D, a new pressure regulator valve which includes a dampening spring entered production Installation procedures for the later type valve are the the same as for previous type*

6) Install pressure regulator valve and spring, then install reverse servo return spring Install servo cover on guide pins, then apply pressure to cover to compress springs making sure that locating sleeve is in alignment with pressure regulator valve bore Install bolts and lockwashers, but do not tighten *NOTF - Us a non-hardening sealer under head of bolt installed directly above vacuum modulator*

7) Before servo cover bolts are tightened, the vacuum modulator hole in servo cover and the through hole in transmission case must be carefully aligned *CAUTION - If these holes are not properly aligned, modulator strut will bind, resulting in improper pressur s, harsh shifts, and possible clutch failure* To properly align holes, separate a used vacuum modulator at the diaphragm and screw the threaded half into modulator hole in servo cover Slide a standard 15/64" drill through both modulator hole and strut hole in case The drill should slide freely through both holes if align-

CONTINUED ON NEXT PAGE



POWERGLIDE (C ntinued)

ment is correct. Align holes by tapping laterally or vertically on edges of servo cover with a soft hammer. With alignment correct, tighten all servo cover bolts to 15-18½ lbs., then remove half of vacuum modulator and 15/64" drill, and install strut and vacuum modulator. *NOTE - Be sure pressure regulator valve spring and reverse servo return spring are properly seated in servo cover.*

8) Adjust low servo band. *See "Band Adjustment" above.*

9) Install converter assembly in converter housing, aligning front pump drive gear lugs with drive slots in converter pump hub. *CAUTION - After converter is installed, check to insure engagement of converter pump hub drive slots in lugs of front pump drive gear. Hold a 6" straight edge against converter-to-flywheel mounting bracket and measure distance from straight edge to machined face of converter housing which should be 9/16". If distance is greater, converter pump hub drive slots are not properly engaged.*

10) Install Converter Holding Tool J-5384 to converter housing. This tool will prevent converter falling out when being installed in engine.

PRESSURE REGULATOR VALVE ASSEMBLY

INSTALLATION IN CAR

(EXCEPT CORVETTE)

TRANSMISSION ASSEMBLY INSTALLATION: Mount transmission on lifting device, then remove Converter Holding Tool J-5384. Proceed as follows:

1) Raise transmission into place and install transmission case-to-engine upper mounting bolts, then install lower and side bolts. *CAUTION - Be careful that converter does not move forward causing disengagement of pump hub drive slots from lugs of front pump drive gear.*

2) Remove support from beneath engine, then raise transmission to final position. Connect body ground strap. With flywheel cover removed, align flywheel bolt holes on converter and install converter-to-flywheel attaching bolts using a jumper to turn engine.

3) Reinstall transmission support crossmember. *NOTE - Two sets of holes are provided f r attachment of cr ssmember to frame as follows: L w r h les ar to be us d with Powerglide, Upper h l s used with Turboglid .* Be sure to reinstall exactly the same number (and thickness) of shims between extension mounting boss and crossmember as were removed. *NOTE - Thes shims maintain correct driv lin angl .*

4) Remove transmission lift equipment and support, then connect propeller shaft to transmission. Connect manual and throttle valve control linkage to transmission. Connect oil cooler lines, vacuum modulator hose, speedometer drive cable to transmission. Reinstall transmission oil filler tube and fill transmission. *S LUBRICATION above.*

5) Adjust all transmission linkage. *S LINKAGE ADJUSTMENT above.*

Form 61 A

CHEVROLET TURBOGLIDE TRANSMISSION

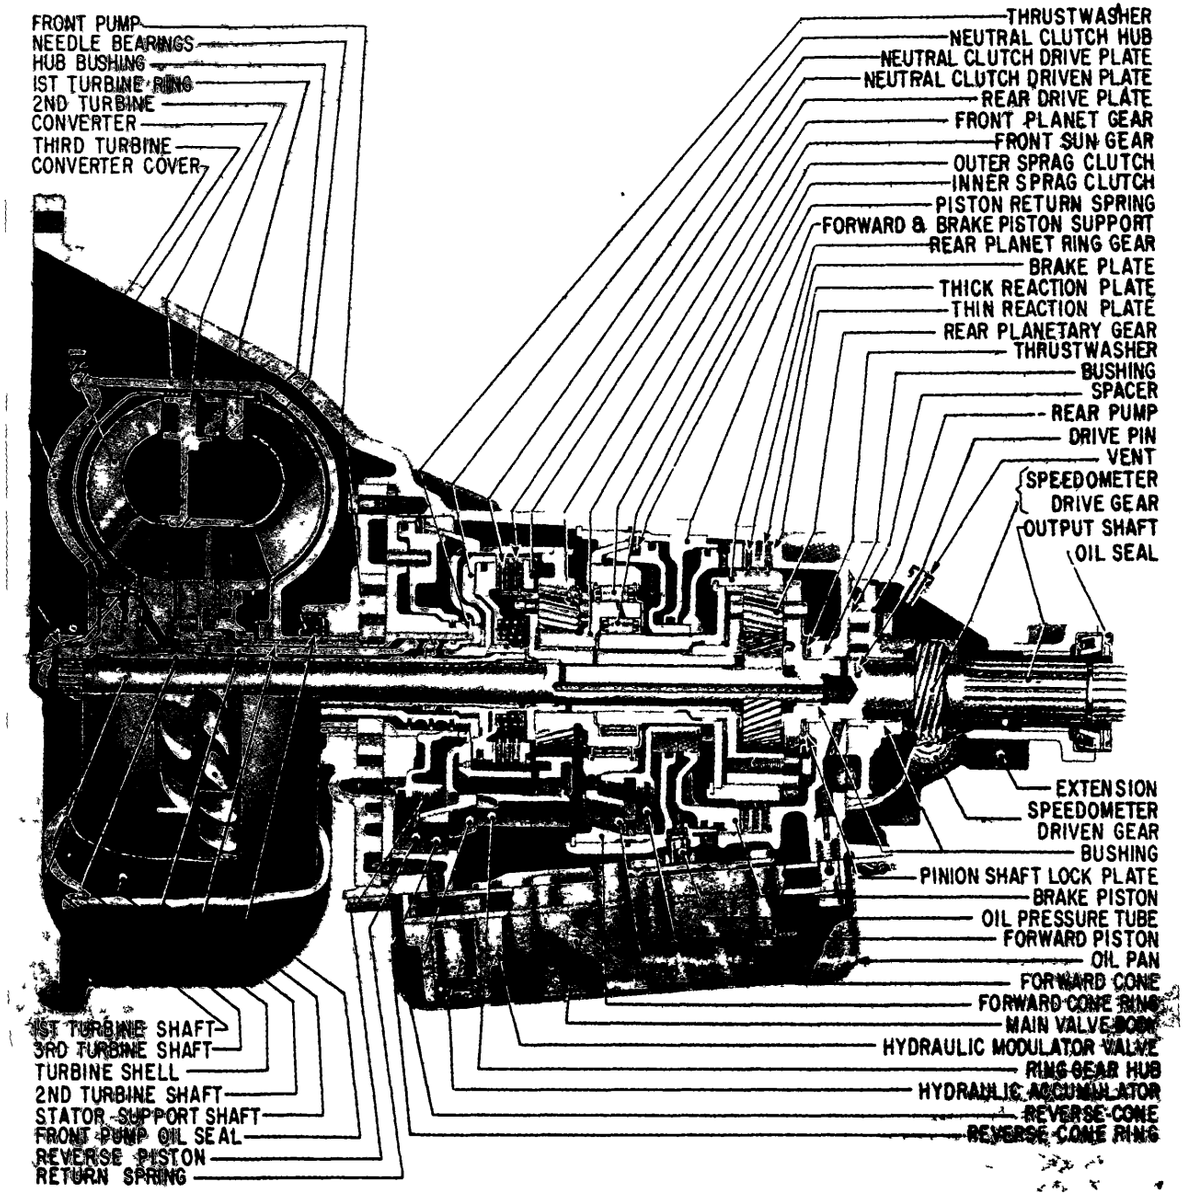
Ch vr let (1957) Opti nal with 283" Engin
Ch vr l t (1958) Opti nal with V8 Engines.

►CHANGES, CAUTIONS, CORRECTIONS

►*1957 TURBOGLIDE TRANSMISSION PRODUCTION CHANGE* A number of transmission parts have been changed in production and are covered in OVERHAUL below

►*1957 TRANSMISSION SELECTOR LEVER INDICATOR CHANGE* Indicator lettering on face of speedometer dial has been changed from "HR" (Hill-Retarder) to "GR" (Grade-Retarder) to prevent misinterpreting "HR" position as "High-Range"

►*1957 THERMAL BYPASS VALVE PRODUCTION CHANGE*· In later transmissions, the thermal bypass valve has been eliminated and replaced by a new plug which acts as a relief valve in the event the oil cooler becomes plugged



►*1957 VACUUM MODULATOR PRODUCTION CHANGE*· A new vacuum modulator, Part No 3745607, identified by a stripe of orange paint, replaces all previous vacuum modulators

►*1958 TURBOGLIDE TRANSMISSION REAR EXTENSION SEAL LEAKAGE CORRECTION (EARLY CARS):* On cars before Transmission Serial No. 1008, leakage around extension oil seal can be eliminated by using Chevrolet Gasket Paste on outer diameter of seal. The press fit at seal on later transmissions has been increased and gasket paste should not be required

►*1958 TURBOGLIDE EXTENSION HOUSING VENT LEAKAGE CORRECTION:* A condition can exist on early cars which makes it possible for the speedometer drive gear to throw oil (from rear pump) out of the extension housing vent. Beginning with Transmission Serial No. B1007, an oil deflector is installed on rear pump housing to prevent oil being thrown out of vent To install the new deflector, Part No. 3754075, on early cars, remove extension housing and two upper bolts securing rear oil pump body to transmission case. Install deflector on body and secure with the two upper bolts. If necessary, to prevent interference between bolts and extension housing when deflector is installed, grind approximately 1/16" from head of bolt.

►*STARTING ENGINE BY PUSHING CAR:* Place control lever in "N" (Neutral) range until car reaches 25-30 MPH. Turn key on and move control lever to "HR" (Hill Retarder) position. After engine starts, move control lever to "N" (Neutral) for engine warm-up. Towing is is not recommended to start car.

►*TOWING TURBOGLIDE CARS:* Cars must not be towed with rear wheels on the ground except with transmission in "N" (Neutral) position and should not be towed in excess of 30 MPH. If car is to be towed a long distance, drive shaft should be removed. *NOTE* – If car has been damaged and transmission cannot be placed in "N" with selector lever, disconnect long rod from idler lever on left side below mast jacket, then pull lever on transmission toward front of car as far as it will go. Move lever toward rear of car from the forward position to the third detent which is "N" (Neutral) position.

1958 CHEVROLET TURBOGLIDE TRANSMISSION (1957 SIMILAR)

DESCRIPTION

The new Turboglide transmission is a non-shifting, hydraulically controlled, planetary type transmission with a five unit torque converter having three turbines which are connected through two planetary units to the output shaft. Band or clutch engagement or disengagement (from standstill to top speed) is eliminated. In addition to the two planetary units, three cone clutches are provided for Neutral, Drive, and Reverse operation. A disc type clutch is used for control of Hill R tarder. A parking lock pawl engages a gear which is integral with the output shaft when selector lever is placed in

CONTINUED ON NEXT PAGE

Form 61 B

CHEVROLET TURBOGLIDE TRANSMISSION (Cont.)

"P" (Parking) position. Transmission clutches and torque converter variable pitch stator are hydraulically controlled by oil pressure supplied by front and rear oil pumps. A valve body mounted on the bottom of the transmission and enclosed in oil contains units to regulate oil pressure, control operation of clutches and provide manual selection of the operating ranges. When transmission is in "D" (Drive) position, torque multiplication is provided by the "first turbine" for starting and low speed power requirements. The "second turbine" is used for intermediate speeds and acceleration purposes and comes into operation at approximately 30 MPH (at full throttle operation). The "third turbine" is used for cruising and high speed operation and comes into operation at approximately 60 MPH (at full throttle). The actual point at which each turbine provides torque to the output shaft is dependent on car speed, engine speed, and throttle position. Oil pressure in the transmission is regulated and controlled in relation to engine torque by means of a diaphragm operated valve which is exposed to engine vacuum and maintains a pressure no higher than is required to hold clutches stationary. Oil temperature is controlled by a thermostatic valve which receives oil leaving the converter. When oil temperature reaches 180°F. the valve completely closes and directs oil through the heat exchanger installed in bottom of car radiator.

OPERATION

NEUTRAL (Selector Lever in "N"): All clutches are released and no drive is transmitted to transmission output shaft. Engine can be started with transmission in "N".

PARK (Selector Lever in "P"): All clutches are released (as in Neutral). The parking lock pawl is engaged with a gear on output shaft which prevents output shaft from rotating. Engine can be started with transmission in "P".

DRIVE (Selector Lever in "D"): Reverse clutch and hill retarder clutch are released. Neutral clutch and forward clutch are applied. Power transmission is through planetary units and output shaft as indicated below. As each of the three turbines are directly connected to a component of the two planetary units, power transmission varies in relation to turbine or turbines in operation depending on engine speed, car speed, and throttle position.

Power Range: As accelerator pressed to set car in motion, the engine drive pump starts, increasing with engine speed, and delivers nearly all of its output to first turbine. Motion of first turbine is transmitted to sun gear of rear planetary gear set, causing transmission shaft to be driven at a reduced rate as the rear planetary gears are forced to "walk" around their ring gear. The ring gear cannot rotate backwards because of its one way clutch. In this phase of operation, greatest transmission torque multiplication is obtained. Transmission gear reduction is 2.67-1, and with torque converter reduction (stator in normal low angle position), the maximum reduction is 3.8-1 at 1700 engine RPM. With stator in high angle, maximum reduction is 4.3-1 at 2700 engine RPM.

Acceleration Range: As car speed increases, angle of oil pumped by converter pump changes due to engine RPM and, because of the angle of first turbine blades, the oil starts to drive the second and third turbine in a progressive and overlapping action while output of first turbine diminishes. Output of second turbine is transmitted to output shaft through the front planetary sun gear at a 1.63-1 ratio. Reduction in the front gear set is obtained by turning the ring gear which causes planet gears to "walk" around sun gears and transmit their speed to the output shaft. The sun gear is prevented from turning backwards by a one way clutch. When second turbine reaches maximum torque, the first turbine is released and freewheels in converter pump oil stream. Like the first turbine declining action, as engine speed continues to increase, less oil pressure plays on the second turbine vanes but more reacts on the third turbine. Because of its direct connection to transmission output shaft, the third turbine is more favorable for high speed acceleration.

Cruising Range: When fluid coupling point of the torque converter is reached, the transmission is in cruising range. At this stage, work of the second turbine is completed and it is released by a clutch to freewheel in converter housing with the first turbine. All output is now from third turbine which is connected mechanically to output shaft at a 1 to 1 ratio.

Variable Pitch Stator: At speeds below 60 MPH, additional torque multiplication is available by depressing accelerator through its detent beyond full throttle position. Stator blades are changed to their high angle, which provides a greater redirection of oil entering the pump, to increase torque multiplication and permits engine speed to increase for greater power output to converter. Above speeds of 60 MPH, at full throttle, the stator freewheels regardless of blade angle, and converter ceases to multiply torque.

Hill Retarder: Hill Retarder clutch is applied and all other clutches are released. The hill retarder may be applied up to 40 MPH to control car forward speed when descending grades. When hill retarder position is applied, the multiple disc clutch on rear planetary gear set ring gear is engaged and all other clutches are released. This drives the first turbine at 2.67 times output shaft speed, while the second and third turbines freewheel. The pumping action of the first turbine creates a turbulence in the converter which effectively brakes the car by increasing engine speed and by transferring energy into heat in the converter oil. The heat is then dissipated by the engine cooling system.

REVERSE: Reverse cone clutch holds ring gear of front planetary gear set and the second turbine stationary and the drive range cone clutch connecting the third turbine to output shaft is also applied. Starting from a standstill in reverse, the reaction within the torque converter is same as for drive range. Inertia of the car tends to hold rear planetary carrier stationary. This causes the planet gears to drive ring gear in reverse. The rear ring gear then turns front planetary sun gear which forces front planetary gears to "walk" around locked ring gear and drive planet carrier and output shaft in reverse.

LUBRICATION

Check oil level at 1000 mile intervals, drain and refill every 25,000 miles.

Capacity - Approx. 3½ qts. (refill), 9½ qts. (after overhaul).

Recommended Oil – Use only Automatic Transmission Fluid Type A (as furnished in containers bearing "AQ-ATF" number).

Checking Fluid Level (Exc. Air Conditioned Cars): With transmission at normal operating temperature, transmission selector lever in "D" (Drive) position, and engine idling. Remove gauge rod located under right side of hood. Wipe with a clean cloth and check oil level. Add sufficient oil to bring level in transmission to the "Full" mark. *CAUTION - Do not overfill.*

Checking Fluid Level (Air Conditioned Cars): With transmission at normal operating temperature, transmission selector lever in "N" (Neutral) position, raise car on a hoist. Remove cap from oil level tube located at rear of transmission oil pan. Add oil to bring level in transmission to top of tube, as follows: Remove speedometer fitting and speedometer drive gear. Add Automatic Transmission Fluid Type "A" through speedometer gear hole.

Draining & Refilling: With engine and transmission at normal operating temperature, stop the engine and remove transmission oil pan drain plug. *(CAUTION – Do not run engine while draining transmission).* After completing draining, replace drain plug and install 3½ quarts of Automatic Transmission Fluid Type A, through the oil dipstick tube (use Funnel J-4264). Start engine and allow to run a few minutes as idle speed, then check oil level. If necessary, add oil to bring level up to "FULL" mark on dipstick.

LINKAGE ADJUSTMENT

►*THROTTLE LINKAGE ADJUSTMENT NOTE: See CARBURETOR on car model pages.*

Manual Control Linkage: Loosen shifter tube lever clamp nut sufficiently to allow upper control rod to move freely in the swivel. Move parking lock and range selector lever on left side of transmission case toward front of car to the "N" (Neutral) detent (3rd position forward). Place shift control lever on steering column in "N" (Neutral) position. With the parking lock and range selector lever and the shift tube lever held in the "N" (Neutral) position, tighten the shifter tube lever swivel clamp nut securely. Check linkage operation to insure the "R" and "D" stops of the transmission control selector plate (mast jacket gate) do not prevent positioning of the selector *(CAUTION – Lever position must be established by transmission Neutral detent and not by the "R" and "D" stops of the control selector plate on the mast jacket).* If necessary, reposition control selector plate to permit normal operation in "R" and "N". *CAUTION* – Improper adjustment of linkage will result in partial pressures on the cone clutches resulting in slippage and ultimate failure of the transmission.

Neutral Safety Switch: Loosen switch assembly mounting screws. Place selector lever in "N" (Neutral) position. Install cotter pin or similar aligning pin in each of the

CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE TRANSMISSION (C nt.)

two holes in switch (one on each side of pointer). Rotate switch to place pointer between holes. Tighten screws securely and remove pins (*NOTE* – Slot in neutral safety switch must be set on center line of tang on shifter tube). If engine will not turn over, loosen screws and rotate switch in the direction necessary until it does. Make sure selector lever is in "N" (Neutral) position when changing switch position.

TROUBLE SHOOTING

DRIVE POOR AT LOW SPEEDS (NO REVERSE, GRADE RETARD NORMAL): Inner overrun clutch assembled backwards.

NO DRIVE EXCEPT IN GRADE RETARD: Both overrun clutches assembled backwards.

NO DRIVE EXCEPT IN GRADE RETARD AND REVERSE: Outer overrun clutch assembled backwards. Forward and neutral clutch not applied due to severe leakage in forward clutch hydraulic circuit.

CAR DRIVES VERY SLIGHTLY IN "NEUTRAL" (REVERSE NORMAL): Neutral clutch not released.

CAR DRIVES NORMAL IN "NEUTRAL" AND "DRIVE" AT LOW SPEEDS (NO REVERSE): Forward clutch not released.

NO DRIVE IN ANY SELECTOR POSITION: Front pump is assembled backwards.

TRANSMISSION WILL NOT SHIFT TO HIGH STATOR ANGLE: Stator control linkage out of adjustment. Converter charging pressure low for one of the following reasons: (a) Leakage which will reduce line pressure enough to cause pressure regulator valve to shut off converter in line. (b) Leakage in converter circuit. (c) Stator control pressure leaking to converter out across front oil seal ring or second oil seal ring on second turbine shaft.

UNABLE TO PUSH START: Rear oil pump drive pin broken or missing.

CLUTCH SLIPPAGE ON WIDE OPEN THROTTLE STARTS: Low oil pressure due to leakage (especially check forward pressure tube "O" ring). Mechanical interference which will prevent forward or neutral piston to fully apply. Neutral or forward clutch facing bond failure.

SECOND TURBINE SEAL RING LANDS INTERFERING WITH I.D. OF STATOR SHAFT: Case locating dowels on engine or dowel holes in case misaligned. Check by indicating front pump bore in case from crankshaft.

GRADE RETARD SLOW TO APPLY: Control linkage out of adjustment, preventing manual valve getting into grade retard position. Leakage to grade retard clutch (check pressure tube "O" ring seal and other sources). Mechanical interference in grade retard piston. Glazed grade retard plates (check neutral clutch for release). If neutral clutch does not release during grade retard, grade retard plates can be damaged.

NO DRIVE, REVERSE NORMAL, NO GRADE RETARD: Reverse clutch not disengaged.

GRADE RETARD BRAKES VIOLENTLY, STATOR PRESSURE READS HIGH ON CHECKING: Vacuum hose disconnected.

SHIFTS FROM STANDSTILL VERY SLOW: Check linkage to ascertain that shift lever is positioned by transmission detents. Accumulator control valve stuck closed. Leakage in hydraulic system (Check pressure tube "O" rings and other seals and gaskets).

SHIFTS FROM STANDSTILL VERY FAST AND HARSH: Accumulator control valve spring too strong or valve stuck open.

TESTING

►*TESTING CAUTION: Do not stall test this transmission at wide open throttle.*

►*TESTING CAUTION: Before testing transmission, check oil level and bring it to the "FULL" mark on dipstick (See LUBRICATION above). Warm transmission to normal operating temperature as outlined below. Adjust engine idle speed to 425 RPM with transmission selector lever in "D" (Drive) range. Adjust throttle linkage (see CARBURETOR on car model pages).*

TRANSMISSION WARM-UP: (In Shop) – Connect tachometer to engine, set parking brake and start engine. Place selector lever in "D" (Drive) range and adjust carburetor idle speed to approximately 750 RPM. Operate engine at this speed for 15 minutes, then readjust engine idle speed to 425 RPM with transmission selector lever in "D" (Drive) range.

On Road – Drive car for approximately 5 minutes with frequent starts and stops. Make sure engine idle speed is 425 RPM with transmission selector lever in "D" (Drive) range. Check fluid level (see LUBRICATION above). *CAUTION* – If fluid level too high, lower the level to "FULL" mark, then drive car five minutes to work bubbles out of fluid.

PRESSURE TEST: Shop – Connect pressure gauge to test point on left side of transmission adjacent to torque converter housing.

Drive Range: Adjust engine idle speed to 425 RPM, selector lever in drive range. Check idle stator pressure, which should be 45-60 lbs.

Reverse Range: With selector lever in "R" Range, stator pressure should be 45-60 lbs.

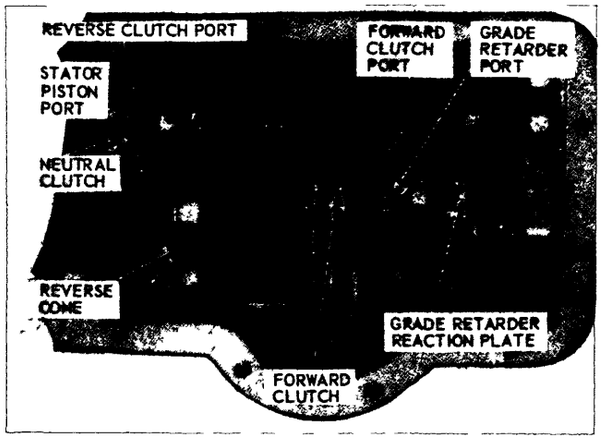
Grade Retard Range: With selector lever in "GR" ("HR" on early models), and foot on brake, accelerate engine to 700-900 RPM, stator pressure should be 45-60 lbs.

Park Range: With selector lever in "P" range, accelerate engine to 800-1000 RPM, stator pressure should be 80-90 lbs.

Neutral Range: Test in same manner as for "P" range.

PRESSURE TEST: Road – Disconnect stator control from throttle. Connect pressure gauge to test point on left side of transmission adjacent to torque converter housing. Connect vacuum gauge to engine.

1) With selector lever in "D" range, pressure should be 45-60 lbs.



2) With selector lever in "D" range and at a car speed of approximately 30 MPH depress accelerator to wide open position, throttle pressure will rise to 135-145 lbs. at 0" of vacuum. At any speed, with foot off throttle, stator pressure should be 50-65 lbs., with engine vacuum reading of 16-25" of vacuum.

3) **Stator Operation** – Reconnect stator control rod to the throttle, place selector lever in "D" range and drive car at 20 MPH. Open throttle quickly, going through detent. Pressure will then drop to 0 lbs., and engine speed will rise when stator is working correctly. *(NOTE – At wide open throttle, stator pressure sh uld read 0 lbs. at any car speed).*

4) With selector lever in "D" range, traveling at 40 MPH, and foot off the throttle, stator pressure should read 50-65 lbs. With selector lever in "HR" range at 40 MPH, and foot off throttle, stator pressure should rise to 85-95 ft. lbs.

►*NOTE:* If engine tachometer is being used, the engine speed will drop (during manual shift from "D" to "HR") and then when hill retarder pressure reaches 85-95 lbs., the clutch will set down and engine speed will increase.

►*CAUTION: Make sure vacuum hose is properly connected to transmission vacuum diaphragm.*

1957-58 TRANSMISSION AIR TEST POINTS

AIR PRESSURE TESTS (WITH TRANSMISSION IN CAR): Drain oil from transmission and remove converter cover pan, transmission oil pan, and main valve body. Install oil pressure tubes in Forward Clutch and Grade Retarder apply ports (see illustration). Use Tool J-4353-1 and an air source of 100 lbs. pressure. Proceed as follows for the five air pressure checks:

Reverse Clutch: Apply pressure to reverse clutch port (see illustration) and visually check that reverse cone moves rearward. Listen for air leaks. If reverse cone does not move, determine whether front pump-to-transmission case gasket is incorrectly installed and blocking oil passages, or if reverse piston is cocked or bound. If air leaks are heard, check for damaged front pump-to-transmission case gasket or for damaged seals in reverse piston.

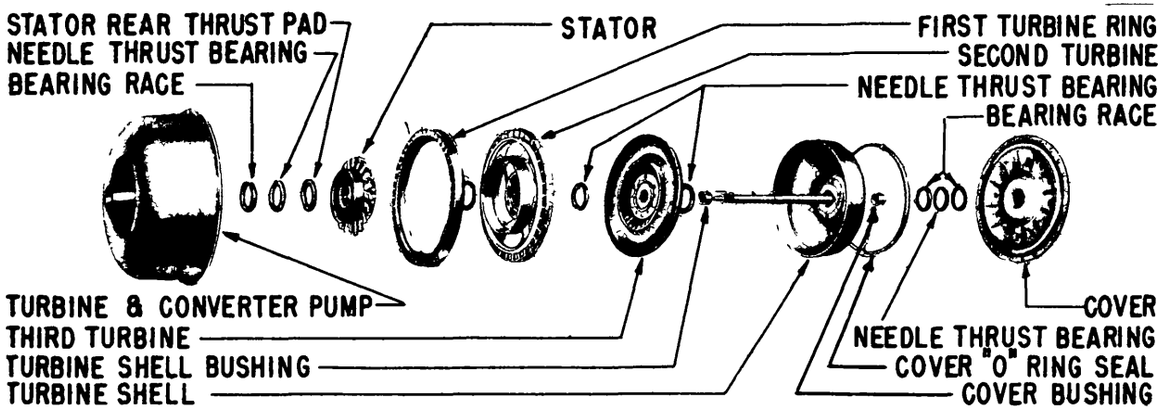
Stator Pist n: Apply air to stator piston port (see illus-

CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE TRANSMISSION (Cont.)

tration), and listen for air leaks. If air leaks are detected, check for a mispositioned or damaged front pump-to-transmission case gasket, broken or warped seal rings on second turbine shaft, defective stator piston seal, or damaged or worn brass seal in the inside diameter of stator support. Should it be determined that stator support brass seal is at fault, the stator support must be replaced as brass seal cannot be replaced separately.

Neutral Clutch: With air applied to neutral clutch port (see illustration), listen for application of clutch and air leaks. If no clutch application is heard, determine if the front pump-to-transmission case gasket is incorrectly positioned and blocking oil passages; otherwise disassemble neutral clutch and check for a locked-up or binding condition. If air leaks are heard, possible causes are a torn or distorted front pump-to-transmission case gasket, warped or broken oil seal rings on second or third turbine shafts, defective brass seal in the inside diameter of second turbine shaft. If brass seal is faulty, replace front ring gear hub and shaft assembly.



Forward Clutch: With oil transfer tube installed, apply air pressure to tube and observe that forward clutch applies. Listen for air leaks. Failure of clutch to apply can be the result of a wedged forward piston or Grade Retarder piston, probably caused by cocked piston "O" rings. A blockage of oil feed orifice in forward and brake piston support could also prevent clutch application. The first place to check if air leaks are found is the "O" ring seals on oil pressure tube in forward clutch port; otherwise, check forward piston-to-support seals.

Grade Retarder Piston: Apply air to grade retarder piston port with oil pressure tube installed (see illustration). Check Grade Retarder application by watching for movement of grade retarder reaction plate which will occur as the brake plates are forced against it by piston moving backward. If grade retarder piston does not move, check for cocked "O" ring seals in both the grade retarder and forward pistons or check for blocked orifice in piston support. Leakage could only occur at either the oil pressure tube "O" ring seal or brake piston "O" ring seal.

TRANSMISSION REMOVAL & INSTALLATION

1957 MODELS

REMOVAL: Place car on jack stands, and remove toe pan plate (under floor mat). Remove spark plugs and disconnect battery ground strap from battery. Disconnect wires from starting motor solenoid and remove starter. Remove underpan mounting bolt retaining oil filler tube clamp and remove filler pipe. *(NOTE - Use masking tape to cover opening in transmission).* On early cars with a thermal by-pass valve, disconnect oil cooler lines and vacuum hose at thermal valve on transmission case. On later cars, disconnect oil cooler lines at plug (replaces vacuum manifold valve). Move lines away from transmission and tie to right frame side rail. Disconnect manual and throttle control rods at transmission levers. Split rear universal joint, then remove propeller shaft and front universal joint as an assembly by sliding complete assembly rearward until free of transmission output shaft. Drain transmission. Disconnect exhaust pipe from crossover pipe and muffler from muffler support bracket. Move exhaust pipe and muffler as an assembly to left and tie to frame member. Remove converter underpan. Install engine support bar or cradle to support engine. Remove the six converter-to-flywheel bolts and nuts. Position hydraulic jack under transmission and attach handling equipment. Remove rear engine mounts from transmission *(CAUTION - Be sure engine is properly supported before removing mounts).* Remove all transmission-to-engine block attaching bolts, then lift accelerator bracket assembly toward front onto the block. Move transmission to rear slightly and install converter holding Tool J-5384. Move transmission to rear off of dowels on engine block and lower transmission from under car.

1957-58 TURBOGLIDE TORQUE CONVERTER ASSEMBLY

INSTALLATION: Raise transmission with proper handling equipment until converter housing is in line with flywheel housing. Remove converter assembly Tool J-5384 from converter housing, then carefully align the "X" mark on converter cover with "X" mark on flywheel *(CAUTION - After removing converter holding tool, be careful that converter does not move forward causing disengagement of the pump hub drive slots from lugs of front pump drive gear).* *(NOTE - "X" marks must be aligned. These marks are not visible after assembly has been completed).* Align bolt holes in flywheel and converter, then enter transmission case into dowels on engine and assemble one bolt on right side of center near the top. Assemble throttle bellcrank bracket on left side of case and assemble two bolts holding case and bracket to engine. Install transmission case-to-engine bolts and tighten to 25-30 ft. lbs. Install converter-to-flywheel bolts and nuts and tighten to 15-20 ft. lbs. Install underpan on case. Install rear engine mountings (both sides) and remove engine support bar or cradle. Complete the installation by reversing removal procedure (above).

1958 MODELS

REMOVAL: 1) Raise car on hoist (see "Jacking & Hoisting" in Suspension & Wheel Alignment Section), then proceed as follows:

2) Drain oil from transmission, then remove oil filler pipe. Disconnect oil cooler lines and speedometer drive cable fitting at transmission (tie lines out of way).

3) Disconnect manual and throttle valve control lever rods from transmission, then disconnect propeller shaft from transmission. Install suitable transmission lift equipment to hoist or jack and attach to transmission.

4) Disconnect engine rear mount on transmission extension, then remove transmission support crossmember. Remove flywheel cover, then use a jumper to turn engine, and remove flywheel-to-converter attaching bolts. *CAUTION - Use care to prevent any shims which may be installed between extension mounting boss and crossmember. The same number of shims must be installed as these affect drive line angle.*

5) Lower rear of transmission slightly so three upper transmission housing-to-engine attaching bolts can be reached using a universal socket and approximately a 39" extension. Remove upper bolts. *CAUTION - Care must be taken not to lower rear of transmission too far as distributor housing may strike fire wall.*

6) Support engine at oil pan rail with a jack, then remove remainder of transmission housing-to-engine attaching bolts. Remove transmission by moving it slightly to rear and downward, then remove from beneath car. *CAUTION - Keep front of transmission upward to prevent converter from falling out. Install Converter Holding Tool J-5384 immediately after transmission removal.*

INSTALLATION: 1) Mount transmission on lifting device. then remove Converter Holding Tool J-5384, then raise transmission into place and install transmission case-to-engine upper mounting bolts. Install lower and side bolts. *CAUTION - Be careful that converter does not move forward causing disengagement of pump hub drive slots from lugs of front pump drive gear.*

CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE (C nt.)

2) Remove support from beneath engine, then raise transmission into position. Connect body ground strap.
3) With flywheel cover removed, align flywheel balance mark "X" and small drilled balance hole on converter, then install converter-to-flywheel attaching bolts using a jumper to turn engine.
4) Reinstall transmission support crossmember. *NOTE - Two s ts of hol s ar provided for attachment of cross-m mb r to frame as follows: Lower holes are to be used with P w rglide. Upp r holes used with Turboglide.* Be sure to reinstall exactly the same number (and thickness) of shims between extension mounting boss and crossmember as were removed. *NOTE - These shims maint in corr ct drive line angle.*
5) Remove transmission lift equipment and support, then connect propeller shaft to transmission. Connect manual and throttle valve control linkage to transmission. Connect oil cooler lines, vacuum modulator hose and speedometer drive cable to transmission. Reinstall oil filler tube and fill transmission. *See LUBRICATION abov .*
6) Adjust all transmission linkage. *See LINKAGE ADJUSTMENT abov .*

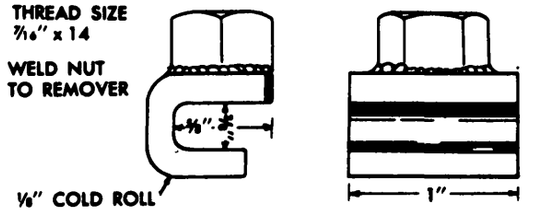
TRANSMISSION DISASSEMBLY

► *TRANSMISSION OVERHAUL CAUTION: Before dis-ass mbling transmissi n, clean outside of case thor-ughly to pr v nt dirt getting into transmission parts. As ach part is r mov d, clean it with cleaning solvent and blow dry with air. DO NOT USE WIPING CLOTH (which may l av lint on parts).*

1957-58 MODELS

DISASSEMBLY (Int Maj r Units): 1) Remove converter assembly from transmission *(CAUTION - Prevent dam-ag to c nv rter utput shaft during removal as the out-put shaft bushing may be misaligned which would make replacem nt of torus shell and shaft assembly neces-sary).* Remove oil pan and gasket. Remove capscrew and retaining clip holding speedometer gear housing in extension and remove housing. Remove extension hous-ing from transmission, noting the square type seal ring on rear pump body.
2) Remove speedometer drive gear from output shaft, using Puller J-5814. Remove rear oil pump body and seal ring, then remove driven gear. Remove drive gear and pin from output shaft *(CAUTION - Drive pin can fall ut if hol on bottom of shaft).* Remove parking pawl spring with needle nose pliers. Remove four bolts retaining valve body assembly to transmission case. *(NOTE -* All three units of valve body will come off as an assembly. Bolts are two different sizes. Rear bolt is hollow to permit oil pressure to valve body).
3) Remove oil pressure tubes between valve body assembly and case *(NOTE -* Tubes are interchangeable and the "O" ring seals are the same). Remove front and rear gasket on valve body.
4) Place transmission with input shaft facing upward, then remove front oil pump cap screws, pump, stator support and reverse piston assembly *(NOTE -* Install Puller J-6585 in threaded holes of front pump housing to remove this assembly). Remove reverse cone and spring from case and place transmission horizontally on bench.
5) Remove neutral clutch and front ring gear assembly, which includes turbine shaft assembly, neutral shaft, and neutral clutch piston. Remove reverse cone ring (tanged to case), with soft drift and hammer. Remove front planet carrier. Remove front sun gear and free-wheel assembly (gear section forward). Remove forward cone retaining ring which holds forward cone in place. Remove forward cone ring and forward cone *(NOTE -* By exerting slight pressure on output shaft, both ring and cone can readily be removed). Remove forward and brake pistons and support as an assembly.
6) Remove rear unit ring gear and output shaft and rear planet carrier as a unit. Also remove both brake clutch plates and aluminum separator. Disassemble rear ring gear from rear planet carrier by removing retaining ring, and remove two races and needle bearings from exten-sion of carrier. Remove caged needle bearing assembly from output shaft.
7) Remove hairpin clip and remove detent control lever which is splined to shaft *(NOTE -* Do not lose the seat and washer from shaft). Remove manual selector lever. Remove parking brake bracket from case (two bolts), then remove parking lock actuator assembly. Remove parking brake pawl, pin, and "O" ring. Pin must be re-moved by driving on front of pin. On early cars with a thermal by-pass valve, remove valve and square seal ring *(CAUTION - Thermal by-pass valve cover is under spring tension).* Remove vacuum diaphragm by holding valve body and removing retainer nut from inside trans-mission case (valve strut will come off with retaining nut). On later cars, remove the plug which replaces thermal by-pass valve.

► *DISASSEMBLY NOTE: For disassembly of the above units, see OVERHAUL following.*



TRANSMISSION OVERHAUL

► *OVERHAUL NOTE: After removal from case, overhaul sub-assemblies or units as follows:*

1957-58 MODELS

TORQUE CONVERTER (Disassembly): Mount converter in a support to avoid damage to turbine output shaft. *(CAUTION - Scribe a mark on converter housing and cover for alignment and balance).* Remove bolts from cover, then remove cover from converter pump. Remove square seal from cover. Remove first, second, and third turbines as an assembly. Remove stator assembly. Re-move stator rear thrust pad, needle thrust bearing and thrust bearing race.
Turbine - Place converter turbine assembly on bench and drive out three drive pins enough to remove first turbine from turbine shell (a small punch should be used to drive pins through the inside of first turbine shell to protrude from first turbine ring). Remove first turbine ring from turbine shell with Tool J-6585, and first turbine ring remover (see illustration). *(NOTE - First turbine ring remover must be fabricated locally).* Remove second and third turbine from turbine shell.

Stator - Remove clutch head retaining screws and front thrust pad, then remove stator freewheel cam, rollers

FIRST TURBINE RING REMOVER TOOL

and springs. Remove stator freewheel race, then remove stator blade front carrier by pushing on rear extension of front carrier. Two dowel pins hold the front carrier from turning. Remove 20 stator blades, stator piston and retaining ring, then remove stator piston from blade rear carrier and remove ring from piston *(CAUTION - B careful not to break cast iron seal ring on stator piston).*
Inspection: Wash all parts in cleaning solvent and blow dry with air *(CAUTION - Do not use rags to dry parts).* Inspect converter pump hub outer surface, and pump thrust washers for galling or scoring. Check converter pump vanes and turbine vanes for looseness or damage. Inspect turbine hubs, turbine thrust washers, stator race and cam rollers for galling or scoring. Inspect converter cover bushing for galling, scoring, or excessive wear. Inspect cam springs for distortion. Inspect stator for galling or scoring and for loose vanes or damage. In-spect loose needle thrust bearing assembly and races for damage.
Converter Cover Bushing Replacement: Use precision type converter cover bushing, Part No. 3737261 for field service replacement (this bushing does not require reaming). Install bushing as follows: Remove thrust washer, needle thrust bearing assembly with a sharp instrument. Remove bushing with a chisel or sharpened tool, taking care not to damage thrust surfaces in bottom of bushing hole. Place new bushing on pilot end of con-verter cover bushing replacer, Tool J-6583, and press bushing into place. Replace thrust washer and needle thrust bearing assembly.
First Turbine Hub Bushing Replacement: Remove needle bearing assembly, then remove bushing with a sharp chisel, being careful not to strike turbine hub. Using Tool J-6561, place pilot bushing, Part No. 3732200 (which requires no reaming), on end of tool and press into hub of first turbine. Install new needle bearing assembly with Tool J-6561.
Reassembly: Stator - Install cast iron seal ring in stator piston and install stator piston in rear blade carrier, being careful not to break cast iron seal ring. Install stator piston retaining ring and install the 20 stator blades. *(NOTE - Trailing or sharp edge of blades should point downward after installation in stator. Neck f stator piston must be pushed fully through rear carrier to install stator blades).* Install stator front blade carrier, indexing the dowel pins in holes in rear blade carrier. Install stator freewheel cam in stator front blade carrier, aligning holes for retaining screws. Install freewheel race, springs and cam rollers with springs in large end of ramp slots of freewheel cam. Install front thrust pad

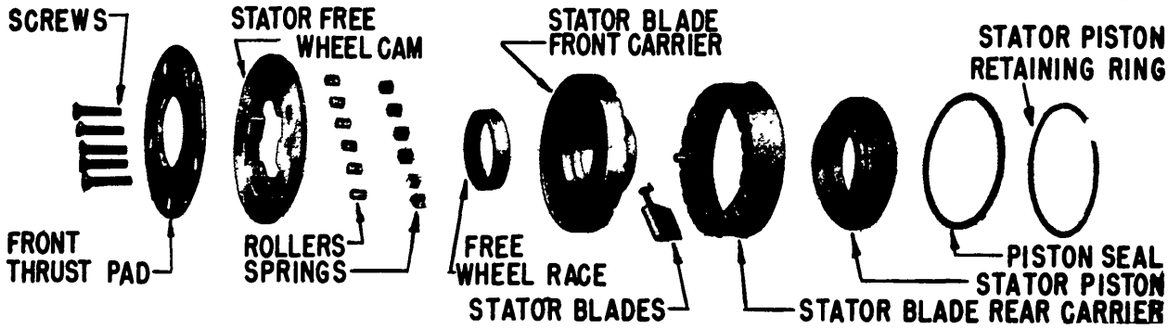
CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE TRANSMISSION (C nt.)

and retain with five screws. Tighten screws to no more than 3-4 ft. lbs.

Turbine - Install needle thrust bearings with Tool J-6561, in the three turbines (needle thrust bearing assembly is the same for each of the three turbines). Support third turbine with suitable bushing while installing thrust bearing *(CAUTION - Do not strike or drive needle bearing on thrust surface. The needle bearing should be installed only by applying force to outer edge of bearing).* Install third turbine in turbine shell with vanes up. Install second turbine in turbine shell with flange upward. Align balance marks, then install first turbine inner ring with inner flat surface facing up in turbine shell. Locating three drive pins in shell with their respective holes in the inner ring can be accomplished with a small drift having the diameter of the pin. Complete installation by seating pins in place with a small "C" clamp.

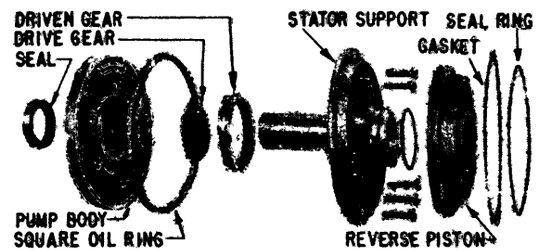
Converter - Install steel spring ring into thrust bearing opening in pump and invert pump and converter assembly on stand and install needle bearing race (thinner washer) in pump. Install needle bearing assembly in pump, then install stator rear thrust pad (heavier of two washers). Install stator assembly into pump with bolts on stator facing up. Mount pump on stand face up, and index converter turbine shaft through pump and stator assembly. Install new square ring seal on converter cover. Place thrust washer, needle bearing, and another thrust washer on face of hub. Install converter cover and align balance marks on converter cover and pump. Install bolts on each side of scribe mark, omitting each fourth bolt, then tighten nuts finger tight. Tighten converter bolts as follows: Tighten every third bolt to 8-12 ft. lbs., (in rotation). Tighten remaining bolts to 8-12 ft. lbs., (in rotation), then tighten all bolts to 13-18 ft. lbs., (in rotation).



1957-58 MODELS

PLANETARY UNITS (FRONT & REAR): Front and rear units are similar and service procedures are nearly identical. Front unit does not have a sun gear or sun gear thrust washers.

►*FRONT PLANETARY UNIT PRODUCTION CHANGE:* Early units had four planetary gears. Later units have only three. On later units, planet pinion shafts are held in place with a lock plate, and are not held in place by staking as on the earlier units.



►*REAR PLANETARY UNIT PRODUCTION CHANGE:* Rear planet carrier pinion pins are held in place on later units with a lock plate identical to the one used on later front planetary units. On transmissions disassembled for service in which the old pressed-in type pins are found, the pins should be removed and discarded. Carefully file out staking burrs in pinion shaft holes in carrier and output shaft. Reassemble, using a new pinion shaft, Part No. 3746468, and lock plate, Part No. 3746470.

Disass mbly: Place planet carrier in a vise (having protected jaws), then mark gear and output shaft for identification and alignment at reassembly. Remove three

1957-58 VARIABLE STATOR ASSEMBLY

hex head lock bolts from bottom of carrier (rear unit); four Allen head bolts (three on later units) from top of carrier (front unit), and install Tool J-6559 to top of assembly, retaining it in place with the lock bolts. Install assembly in an arbor press with the output shaft downward, then install a suitable drift in hole in carrier and press on sun gear (rear unit), flange of output shaft (front unit) until output shaft is away from carrier and planetary gear shafts are freed from carrier *(NOTE - On later transmissions, the pinion shaft lock plates must be removed).* When carrier is separated from output shaft, all parts of the assembly can be removed. Be careful to keep planet pinions on pinion shafts so as not to lose pinion needle bearings *(CAUTION - On early cars with pinion shafts staked in carrier and output shaft, do not attempt to remove pinion shafts by breaking the four way stake. Pinion shafts must be removed by disassembly of planet carrier only).* Remove Tool J-6559 from carrier. Install the part containing pinion shafts into a vise and remove needle thrust bearing assembly, thrust bearing retainer, needle bearing race, and on rear unit, remove sun gear and sun gear thrust washer. Place a dummy shaft (old pinion shaft or a wooden dowel the same size as pinion shaft) to end of pinion shaft and slide a knife blade between lower thrust washer and

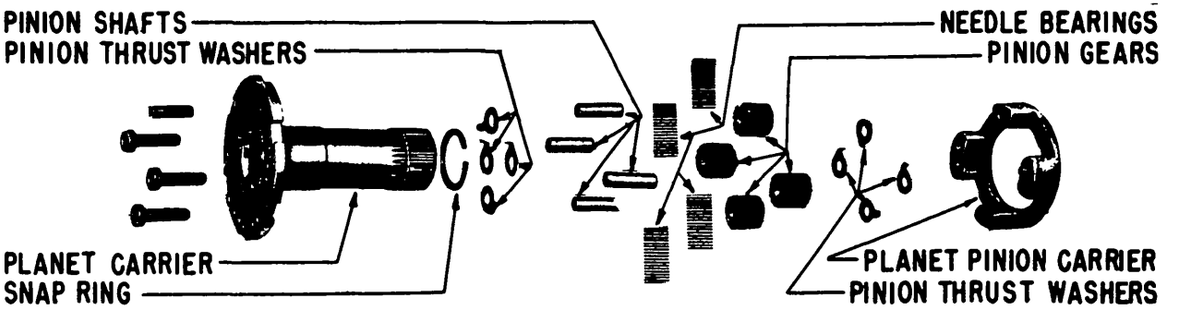
1957-58 FRONT PUMP & REVERSE PISTON ASSEMBLY

pinion shaft holder. Lift up on knife and slide lower bearing thrust washer onto dummy shaft. Remove other two (three on early type front units) pinion assemblies in the same manner. On units with early type front and rear units, pinion shafts may be removed by knocking shaft out of holder (carrier or output shaft) with a drift no larger than the inner circle formed by staking marks *(CAUTION - Damaging the staking marks will ruin retaining quality of carrier or utput shaft and nec ssitat replacement of these parts).*

Inspection: Wash all parts in solvent and blow dry with air. Check planetary pinion gears and sun gear for nicks or other tooth damage. Check thrust washers for wear or scoring and replace all worn or damaged parts. *(NOTE - The output shaft bushing is pr cision bor d in place during assembly, and is not r plac abl).* Inspect planetary needle bearings closely and if excessive wear shows, replace all the bearings in that pinion. Check pinion shafts and replace if worn (install new pinion shafts in output shaft half of the assembly).

Reassembly: *(NOTE* - If pinion shafts have been installed in output shaft, install output shaft in vise, if pinion shafts are not removed, install carrier in vise for installation of pinion gears). Using a dummy shaft, assemble needle bearings, and spacer (17 in each end), in one of the planet pinion gears (use cup grease sparingly to aid in assembling and holding needle bearings in place). Install pinion thrust washer over pinion shaft with tang indexed to small lock hole in output shaft (or carrier). Index dummy shaft with pinion gear assembly, to pinion gear shaft, and slide pinion gear assembly over shaft. Repeat operation for other pinion assemblies. Install sun gear rear thrust washer into output shaft with tang of thrust washer down and into lock hole in output shaft. Install sun gear. Install thrust bearing retainer in rear planet carrier. Install sun gear needle bearing race and needle thrust bearing assembly in rear planet carrier (use a slight amount of lubricant to retain in position). Install pinion thrust washers with tangs up. *(CAUTION - Make sure that no metal is shav d from pinion shafts during assembly as false clearanc r adings will b obtained).* Align alignment marks on carrier to alignment marks on output shaft and insert dowels of carrier into their respective holes in output shaft *(CAUTION -* While installing carrier to output shaft, align tangs of thrust washers to lock holes in carrier). To accomplish mating of carrier and output shaft, install assembly in arbor press in same manner as that used for disassembly, and press into position. Install the lock bolts and tighten to 18-22 ft. lbs. Check clearance of planet gears between washer and pinion (do not check between washer and carrier), this clearance should be .006-.030".

CONTINUED ON NEXT PAGE



CHEVROLET TURBOGLIDE TRANSMISSION (C nt.)

1957-58 MODELS

FRONT OIL PUMP & REVERSE PISTON: Disassembly - Remove gasket and the square oil seal ring. Remove reverse cone piston by using air pressure and applying nozzle approximately ½" from reverse port in stator support. Remove square seal ring from outer diameter of reverse piston, and square seal from stator support hub. Remove five hex bolts holding stator support to front oil pump body and remove oil pump body from stator support. Remove oil pump drive gear and driven gear. *(NOTE* - Lug on drive gear is installed to front of pump body. This lug mates with slot in converter housing hub).

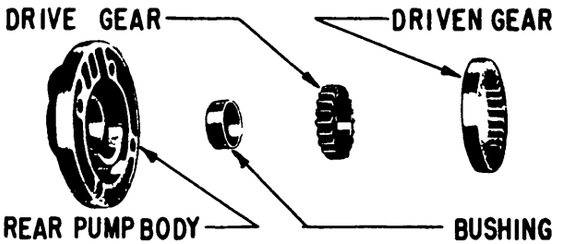
Inspection: Wash all parts in solvent and blow out all oil passages *(CAUTION - Do not use rags to wipe parts).* Inspect all parts for nicks or scores. Inspect seals for wear, hardness, damage, or evidence of oil leakage. If pump body oil seal is damaged, pry out and install new seal using Tool J-6584. Inspect splines on stator shaft for wear, and check both ends of shaft inner diameter for wear. Inspect facing material on reverse piston and ring for cracks or flaking and replace if found questionable. Inspect reverse cone and replace if excessive heat indicated. Inspect pump body bushing for galling or scoring. Check clearance between pump body bushing and converter pump hub. Maximum clearance should be .005". With parts clean and dry, install pump gears and check clearance between O.D. of driven gear and body. This clearance should be .0025-.0055". Check clearance between internal gear and crescent. This clearance should be .003-.009". With scale and feeler gauge, check gear end clearance by placing scale across gears and housing. Clearance between scale and gears should be .0005-.0015".

R assembly: Remove gears from pump after checking and lubricate with automatic transmission fluid, then reinstall gears in pump body *(NOTE* - Drive gear is installed in pump body with lug toward body. Lug mates with slot in converter housing. If drive gear is installed improperly, pump will not operate). Assemble stator support through drive gear and align attaching bolt holes. Install the five lock bolts but do not tighten. Install Concentricity Gauge J-6560 over front extension of stator support to align stator support to pump body, then tighten the five lock bolts to 18-22 ft. lbs., and remove gauge.

TYPICAL FRONT PLANET CARRIER (NOTE - THREE PLANET PINIONS USED IN LATER PRODUCTION)

Install square seal to stator support hub (lubricate seal with automatic transmission fluid), install outer square seal ring. Guide piston over dowels and press with fingers to seat in place (dowels are off center to facilitate correct mating of parts). Install square seal to outer edge of support. Install gasket on oil pump housing *(NOTE - Reverse cone spring is not installed at this time due to operation for selection of correct size thrust washer, during which spring is removed).*

REAR PUMP: Disassembly - Remove pump gears and wash parts with solvent. Blow out all oil passages and check parts for visible damage. Install gears and check all clearances which are the same as for the front pump (see above). *NOTE* - Use output shaft in place of converter to make check for clearance between output shaft and pump bushing.



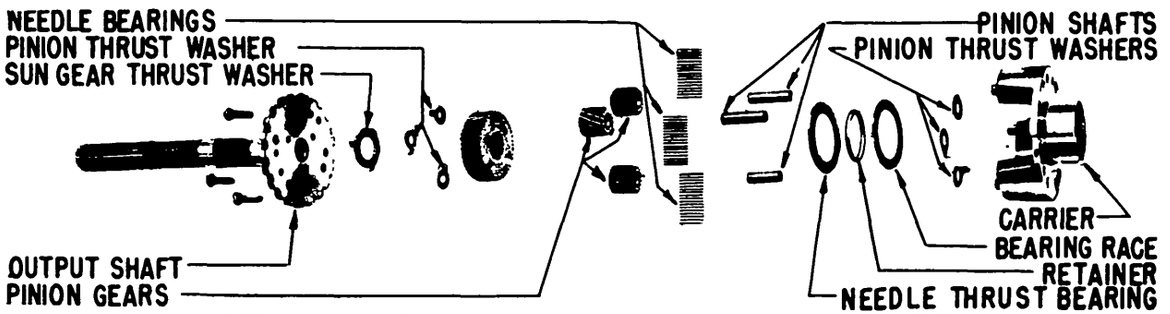
Rear Pump Body Bushing - Use precision bushing, Part No. 3727490, which requires no reaming, for service replacement. Cut bushing with a chisel and remove from pump body. Press new bushing into pump body with Tool J-6582. Bushing should be flush with neck of pump body on the inside, and flush to .010" below front surface of pump body.

Reassembly: Lubricate all parts with automatic transmission fluid. Reverse the disassembly procedure.

1957-58 MODELS

FRONT SUN GEAR FREE WHEEL ASSEMBLY: Disassembly - Remove needle thrust bearing assembly in opening in the rear of sun gear. Remove snap ring in outer cam from rear of assembly with a screwdriver. Remove forward cone freewheel sprag assembly, and outer bearing from sun gear (sun gear may have to be rotated clockwise to freewheel out of cam). Remove sprag assembly from outer cam *(NOTE* - The sprag assembly should not be disassembled. An arrow stamped on outer cage of sprag assembly designates front of transmission). Remove sheet metal retainer from sun gear, using pliers and bending retainer at staking points. Remove ring gear freewheel sprag assembly and bearings.

Inspection: Wash all parts in solvent and blow dry with air *(CAUTION - Do not use rags to wipe parts).* Inspect



1957-58 REAR PUMP ASSEMBLY

inner race (sprag bearing surface) of cam for excessive scoring or burning. Also check lugs on outer perimeter of cam for nicks or burrs. Check bushings in sun gear for looseness or bushing scoring. Replace if necessary. *(NOTE* - Bushings must be replaced in pairs with sun gear removed from freewheel unit). Inspect front sun gear teeth for nicks and burrs and for fit of sun gear into front planetary unit. Inspect internal and external races (sprag bearing surfaces) of sun gear for excessive scoring or burning. Inspect sprag bearing for excessive wear. Check sprag assemblies and if wear is indicated, replace the assembly.

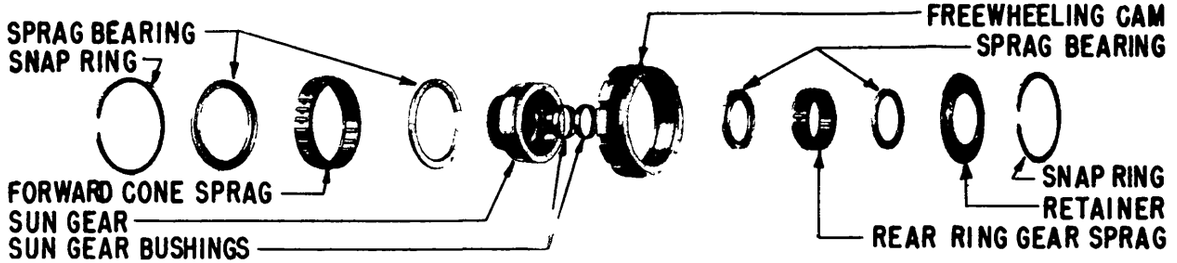
Front Sun Gear Bushing Replacement - Use precision bushings, Part No. 3727244, which require no reaming, for service replacement. *(CAUTION - Do not attempt replacement of these bushings with freewheel unit assembled).* Remove old bushings with Tool J-6581, using removal end of tool. *(CAUTION - Before installing bushings, note position of oil grooves in bushings. These grooves must point outward to maintain oil reservoir in sun gear).* Using Tool J-6581, mount sun gear in press and press bushings into place.

R assembly: Install front retainer, then large sprag front bearing (brass) into cam. Install sprag into cam *(NOTE* - Stamped arrow on outer cage of sprag assembly indi-

TYPICAL REAR PLANETARY CARRIER & OUTPUT SHAFT ASSEMBLY

CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE TRANSMISSION (C nt.)



cates front of transmission), compress unit into cam with fingers (do not force). Install large sprag rear bearing (brass) into cam, then set aside for further assembly. Install front bearing (brass) into rear of sun gear. Install sprag, then install rear bearing (brass) into sun gear. Index tang of new seal retainer into hole in rear of sun gear and clamp in vise, using a steel block and wood block, and stake retainer into place using a staking tool which must be sharp and give a "fingernail" impression *(CAUTION - Shield retainer must be held snug to rear of sun gear while staking operation is performed. Be very careful not to bend shield).* Index sun gear into forward cone sprag, twisting counterclockwise to enable sprag cams to twist, allowing sun gear race to seat under sprags while twisting. Install rear bearing into cam. *(NOTE - Sprags are assembled correctly if units will slip while holding outer cam stationary and turning sun gear clockwise as viewed from front).*

1957 MODELS

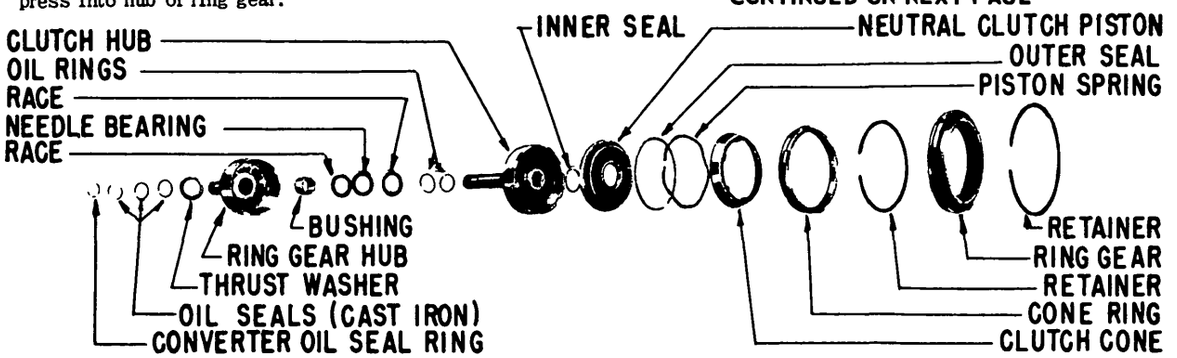
►*NEUTRAL CLUTCH PISTON & SPRING PRODUCTION CHANGE:* A new piston is being used in production and two release springs are being used in place of the former single spring. These springs are the same as the single original spring but must always be replaced in pairs from the same source and have the same die mark to assure proper nesting. Matched springs are furnished in service package, Part No. 3746425. When installing springs, the ends should be toward piston and the gaps of both springs must line up.

►*NEUTRAL CLUTCH CONE RING PRODUCTION CHANGE:* Transmissions bearing a date of Feb. 1, 1957 or later have a new clutch cone ring to which a .045-.035" step has been added to rear face. Slots in clutch hub have been increased .040" in depth to permit removal and installation of the ring retainer. Special procedures are required for disassembly and reassembly of unit using the new rings, as follows: In order to fully depress cone ring, install a small "C" clamp on each side of clutch hub assembly so that the adjustable foot of clamp is seated partly on step of cone ring and partly on clutch cone. Cone ring retainer can then be either removed or installed.

NEUTRAL CLUTCH & FRONT RING GEAR: Disassembly - Remove converter turbine shaft oil seal ring from front of ring gear hub shaft. Remove three turbine shaft oil seal rings and lift converter turbine shaft ring gear thrust washer off shaft *(NOTE* - This washer is a selective fit for proper clearances within transmission). Remove front planet ring gear retainer ring with a sharp instrument and remove ring gear from hub. Remove hub from turbine shaft and neutral clutch assembly. Remove oil seal rings from turbine shaft. Remove race, needle thrust bearing assembly and rear race from turbine shaft. Remove neutral cone ring retainer ring from neutral clutch assembly *(See "Neutral Cone Ring Production Change" above),* then remove cone ring, cone and cone piston return springs (or spring). Remove neutral clutch piston by putting air pressure into ball check hole in hub (Piston is doweled to hub and will not rotate independently of hub). Remove neutral cone piston outer square seal ring, and stator support square seal ring from stator support hub. *NOTE* - Ball check in hub is not removable.

1957-58 SUN GEAR FREE WHEELING UNIT

Inspection: Wash all parts in solvent and blow dry with air. *(CAUTION - Do not use rags to wipe parts).* Inspect splines in hubs for nicks or burrs and check hub for fit into third turbine. Inspect ball check for looseness. If leakage is suspected, hub may be checked by filling cavity with oil and noting any leakage at ball check. Inspect inner race of hub for excessive scoring or burring (surface on which piston moves must be microsmooth to eliminate possibility of oil ring breakage). Check all ring lands for nicks or burrs which may restrict ring movement. Check bushing in center of hub. If bushing is scored or loose, or inner race is damaged, replace hub and shaft assembly. Check neutral cone piston for burred or nicked groove for piston outer seal, or inner race being scored or pitted. Any surface roughness in contact with rubber seals will cause seal failure. Inspect neutral cone inner and outer facings for cracks or flaking. If questionable, replace as necessary. Check all tangs and keyways for proper engagement (the smallest burr or tang will hamper assembly). Inspect neutral cone surface and if excessive heat is indicated, replace the part.



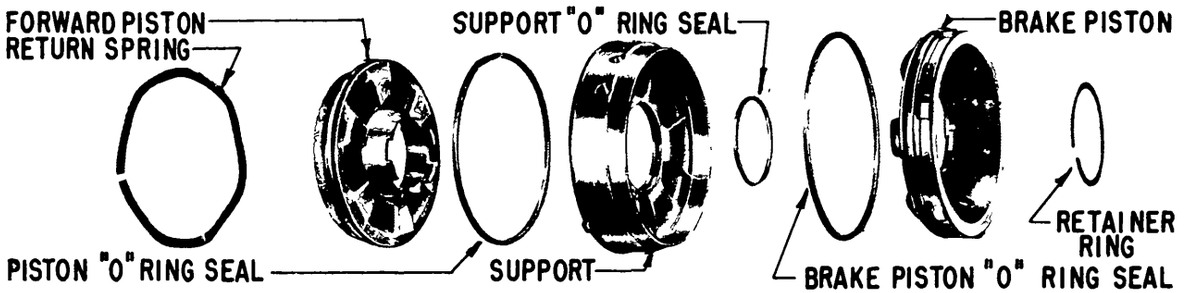
Front Ring Gear Hub Bushing Replacement - Use precission bushing, Part No. 3727301, which requires no reaming, for service replacement. Mount hub in vise (with jaws protected). Remove bushing with chisel *(CAUTION - Do not strike hub of ring gear).* Mount hub in arbor press and using Tool J-6643, pilot bushing on end of tool and press into hub of ring gear.

Reassembly: *(NOTE - Lubricat rubb r s als with aut - matic transmission fluid b f r assembling).* Install neutral cone piston inner square seal ring to center raised portion of hub. Install neutral piston outer square seal ring on piston. Install neutral clutch piston into hub, indexing hole in piston to fit dowel in hub. Apply hand pressure evenly around piston to facilitate installation. Install neutral cone piston return spring, neutral cone and cone ring, indexing lugs to keyways in hub. Install neutral cone ring retainer ring in groove in hub, seating it fully in groove. Place unit on bench with turbine shaft up and install needle thrust bearing race, needle bearing assembly and front race over turbine shaft of neutral cone hub. Install two piston hub oil seal rings (cast iron) on turbine shaft. Install front ring gear hub over neutral piston and turbine shaft assembly *(CAUTION - Be careful not to break il s al rings during installation).* Lift the assembly, keeping units together, and mount in vise. Key front planet ring gear to ring gear hub with large tapered portion of ring gear upward, or retainer cannot be installed. Install front ring gear retainer ring in hub and make sure it seats in bottom of groove. *NOTE - Oil s al rings and sel ctiv thrust washers are not install d at this tim as it would be necessary to remove them for s l cting prop r thrust washer during reassembly.*

1958 MODELS

NEUTRAL CLUTCH & FRONT RING GEAR: Disassembly - Remove converter turbine shaft oil seal ring from front of ring gear hub shaft. Remove three turbine shaft oil seal rings and lift converter turbine

CONTINUED ON NEXT PAGE



1957 NEUTRAL CLUTCH & RING GEAR ASSEMBLY (FIRST TYPE)

CHEVROLET TURBOGLIDE TRANSMISSION (C nt.)

shaft ring gear thrust washer off shaft- *NOTE - This wash r is s l ctiv fit for proper clearances within transmission.* Remove front planet ring gear retainer ring with a sharp instrument and remove ring gear from hub. Remove hub from turbine shaft and neutral clutch assembly. Remove two third turbine shaft seal oil rings from turbine shaft, then remove plate retaining snap ring and lift out rear drive plate, clutch drive plates, and driven plates. *NOTE - Plate retaining snap ring is staked in place. Remove staking by driving on snap ring with a punch and hammer.* To remove spring retainer snap ring, place neutral clutch assembly in an arbor press and compress springs with Tool J-5133 and J-7150, then remove snap ring and slowly release press. Lift off spring retainer and remove 16 springs. To remove neutral piston apply air to check ball (piston will blow out). Remove neutral piston outer seal and piston hub seal. *NOTE - Ball ch ck in n utral clutch hub must be free to move off s at .030" minimum and hole should be free of chips and dirt. Ball ch ck is n t removable.*

Fr nt Ring G ar Hub Bushing Replacement - *CAUTION - Th f llowing procedure applies only to early 1958 cars. On lat r units, the front ring gear hub must b r plac d as a c mpl te assembly if bushing requir s r plac ment.* Use precision bushing, Part No. 3727301, which requires no reaming, for service replacement. Mount hub in vise (with jaws protected). Remove bushing with chisel. *CAUTION- Do not strike hub of ring g ar.* Mount hub in arbor press and using Tool J-6643, pilot bushing on end of tool and press into hub of ring gear.

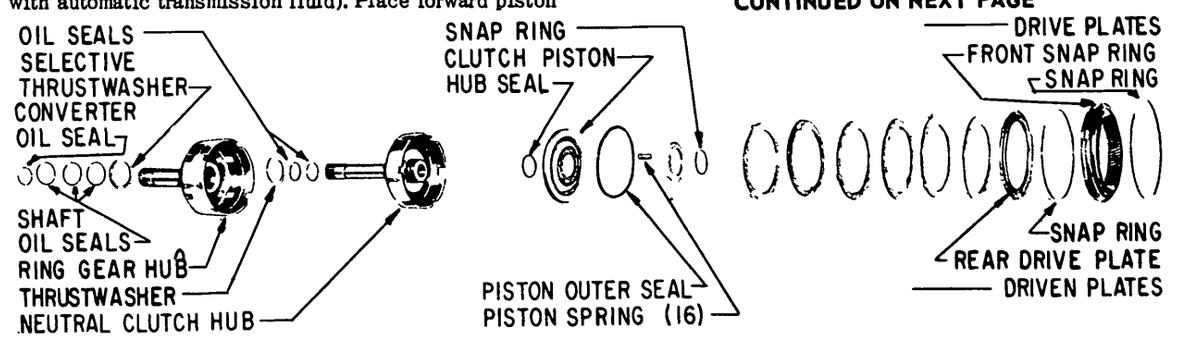
R ass mbly: *NOTE - Lubricate rubber seals with automatic transmissi n fluid before assembling.* Install neutral clutch piston hub seal ring to center raised portion of hub, then install neutral clutch piston outer seal on piston. Install neutral clutch piston into clutch hub (apply hand pressure evenly around piston to aid in piston installation). Arrange 16 piston springs on neutral clutch piston in a circle in piston spring groove, then place spring retainer on springs. Place assembly in an arbor press, then install snap ring in approximate position and compress springs with Tool J-5133 and J-7150. Make sure snap ring is properly seated, then remove neutral clutch from arbor press. Install externally tanged drive plates and internally splined driven plates alternately in neutral clutch hub starting with a drive plate. Install rear drive plate and secure all plates with snap ring. Stake retainer plate against snap ring in three places. Install ring gear hub bushing, then two third turbine shaft seal rings. Insert neutral clutch hub into front ring gear hub being careful not to break seal rings on third turbine shaft. Key front ring gear to ring gear hub (larger tapered portion of ring gear must be up or snap ring cannot be installed). Install front ring gear retainer ring in hub, making sure it seats fully in bottom of ring groove. *NOTE - Oil seal rings and selective washers are not installed at this time as it would be necessary to remove them for selecting proper thrust washer during assembly.*

1957-58 FORWARD & BRAKE PISTON & SUPPORT ASSEMBLY

1957 MODELS

FORWARD PISTON, BRAKE PISTON & SUPPORT: Disassembly - Remove return spring from forward piston, making sure that facing material is not chipped from piston cone surface. Remove retainer holding brake piston to forward piston. Mount assembly into Holding Fixture J-6580-1 indexing tang of support to keyway in holding fixture, then place in arbor press. Index Tool J-6580 into spline of hub of forward piston and press piston out of support and brake piston. Remove support from holding fixture and remove forward piston. Reverse support and install with brake piston down into holding fixture, then press out brake piston in the same manner as for forward piston. Remove parts from holding fixture and remove "O" rings from support, and square seal rings from forward and brake pistons.

Inspection: Wash all parts in cleaning solvent and blow dry with air. Inspect splines of hub for nicks or burrs and check hub of brake piston for fit into hub of forward piston. Inspect all surfaces contacting oil seal ring surfaces for scoring or burning, and check seal rings for damage. Inspect forward cone ring and piston for cracks or flaking in facing material. If condition of material is questionable, replace the necessary parts. Inspect forward cone surface and replace if excessive heating is indicated. Inspect hill retarder composition plates and replace if damaged.



Reassembly: Install new "O" ring in support and square seal rings on brake and forward piston (lightly lubricate with automatic transmission fluid). Place forward piston on bench with splines facing up. Index support over hub of forward piston and hand press together, noting position of raised ribs of piston to mate with cavities in support. Key the splines of hub on hill retarder piston to splines of forward piston and align tang with hill retarder piston between pressure tube holes in support, then press together evenly to avoid damage to seals (rear piston must be down far enough to enable retainer to be installed and fully seated). Install return spring to forward piston taking care not to chip off facing material. *(CAUTION* - Make sure spring is indexed properly with notches in forward cone ring). Install forward cone ring and align tang of ring to tang of support.

1958 MODELS

FORWARD PISTON, BRAKE PISTON & SUPPORT: Disassembly - Disassembly is the same as for 1957 models (see above).

Reassembly: Install new "O" ring in support and the square seal rings on brake and forward piston (lightly lubricated with automatic transmission fluid). Install brake piston into support, centering any one of the six lugs between the two pressure tube holes in support. Align lugs and supports of forward piston and brake piston and install forward piston. Use Tool J-6580 to to press the two pistons together if necessary. Install retainer ring in forward piston hub, making sure it is fully seated. Install return spring to forward piston. Tangs of spring must be toward front of transmission, and gap of spring should be centered over pressure tube hole that is most counterclockwise as viewed from front of transmission. Install forward cone and cone ring,

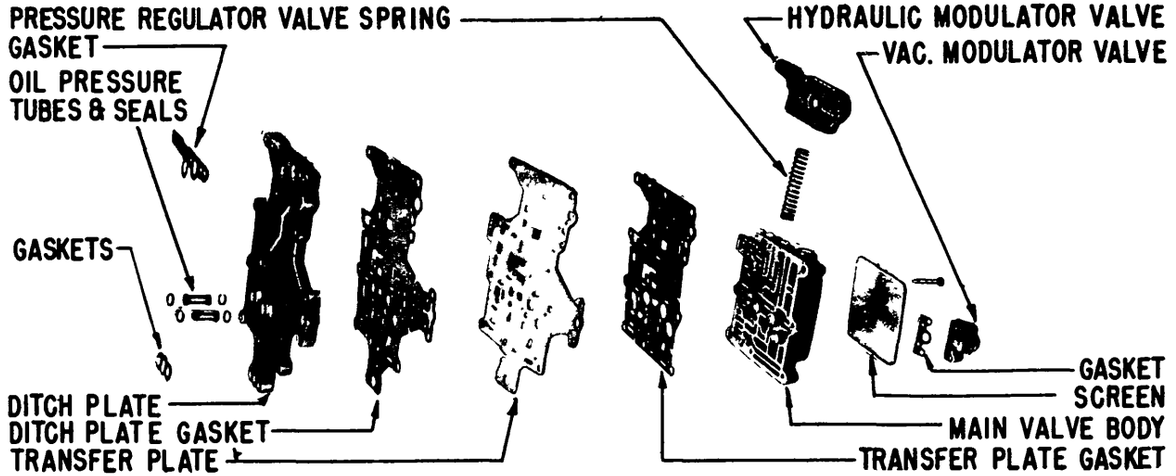
CONTINUED ON NEXT PAGE

1957 (SECOND TYPE) & 1958 NEUTRAL CLUTCH & RING GEAR ASSEMBLY

CHEVROLET TURBOGLIDE TRANSMISSION (C nt.)

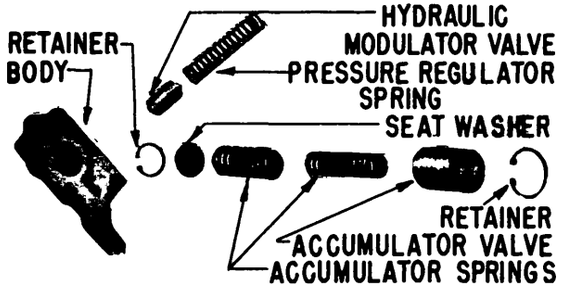
indexing spring tang to cone ring notches and tang of cone ring to tang support.

1957-58 MODELS



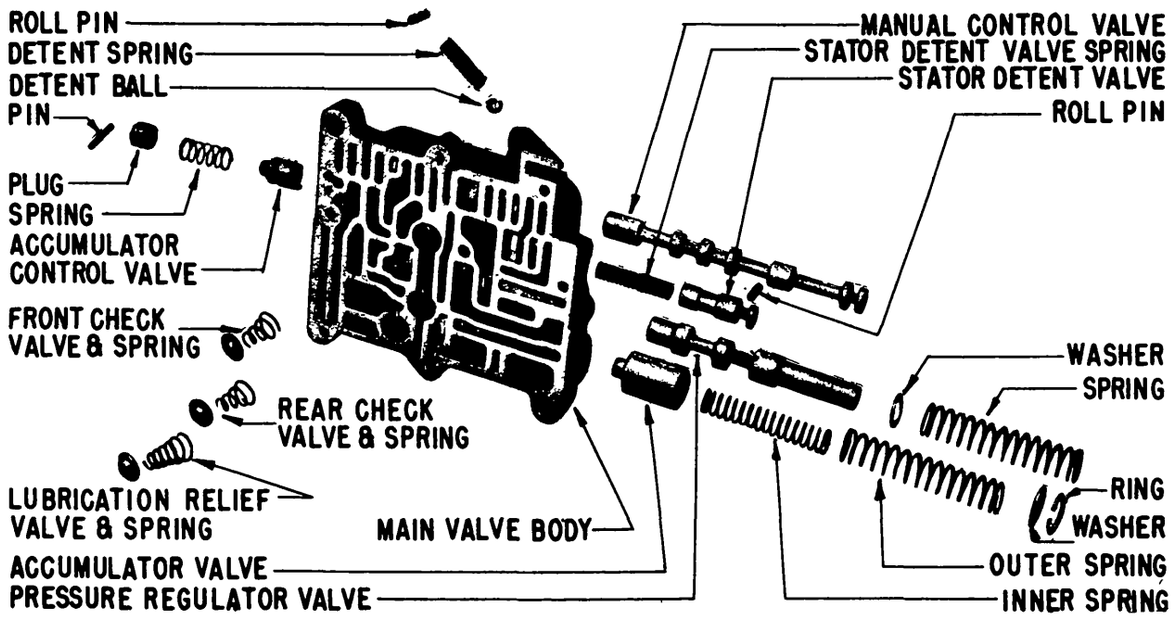
TRANSMISSION CASE REAR BUSHING REPLACEMENT: The case rear bushing, Part No. 3732210 is a precision type and requires no reaming after installation. Place transmission case on bench with rear portion facing up, then cut bushing with a cape chisel and remove from case. *(CAUTION - Be careful not to damage the aluminum transmission case).* Install bushing into case using Tool J-6582, from inside of case.

1957 MODELS



►*CONTROL VALVE BODY PRODUCTION CHANGES:* A new main valve body, Part No. 3746447, including the hydraulic modulator valve assembly is being used in production to increase line pressure from 60-170 lbs., to 90-200 lbs. The valve body transfer plate has been replaced by a new plate, Part No. 3745601, which has the .13" x .50" orifice for stator feed oil reduced in size to .062". Two ditch plate straps, Part No. 3747241, and 3747242 are used to prevent oil leakage with the increased oil pressure. New bolts with a torque specification of 8-12 ft. lbs. are being used. The stator detent spring and the manual detent spring have also been changed.

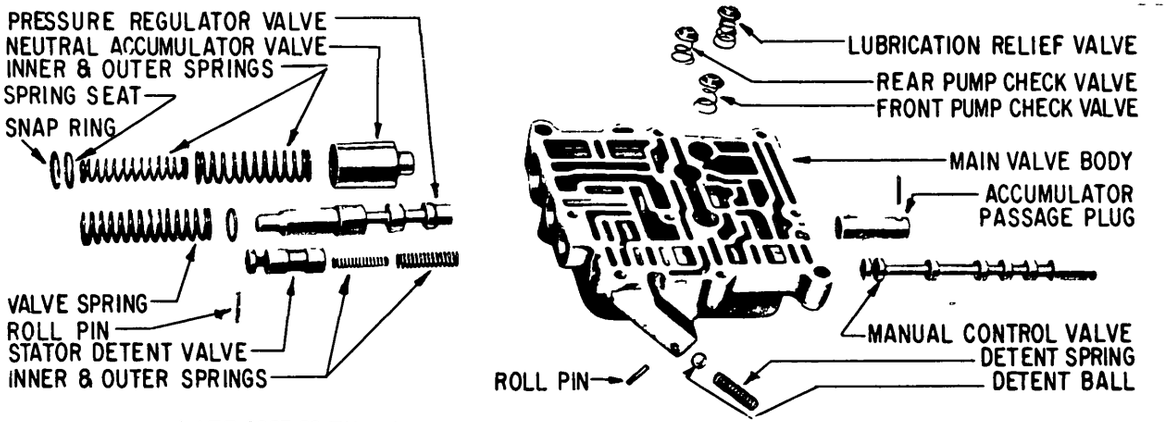
CONTROL VALVE BODY: Disassembly - Remove both oil pressure tubes (if they did not stay on support). Remove valve body screen and manual valve. Remove both gaskets between valve body and transmission case. Remove vacuum modulator valve body and gasket. Remove modulator valve body *(NOTE* - Hold valve body securely while removing bolts as this unit is spring loaded by pressure regulator valve spring). Remove accumulator valve by installing hydraulic modulator valve body in a vise (or use a "C" clamp) to depress the accumulator valve while the accumulator valve snap ring is being removed *(CAUTION* - This valve is under about 90 lbs. pressure). Then remove seat and inner and outer springs and accumulator piston. Remove hydraulic modulator valve from body. Remove pressure regulator spring, valve, and spring seat washer. Remove main valve by removing screw retaining parking pawl spring strut, then remove other valve body locating screw holding valve body to ditch plate. Reverse valve body and remove seven bolts holding ditch plate to valve body. Separate ditch plate (aluminum) from transfer plate (steel) and valve body. Remove gasket between ditch plate and transfer plate, remove transfer plate, then remove gasket between transfer plate and valve body. Remove front and rear pump check and lubrication relief valve and springs *(NOTE* - Front and rear check valve springs are interchangeable. Lubrication relief valve spring is different and is not interchangeable. The three valves are interchangeable). Remove accumulator check valve from ditch plate, then remove accumulator control valve plug roll pin, plug, valve and spring. Remove accumulator valve snap ring (in end of valve body), spring seat, inner and outer springs and accumulator piston. Remove the seven socket head pipe plugs from valve body. Remove detent roll pin, spring, and detent ball.



Inspection: Wash all parts in solvent and blow dry with air *(CAUTION - Do not use rags to wipe parts).* Inspect all springs for distortion or damage and all valves for nicks, burrs, galling, or scoring. Check valves and pistons for free operation in their respective bores. Inspect lands of manual valve for wear or scratches. In-

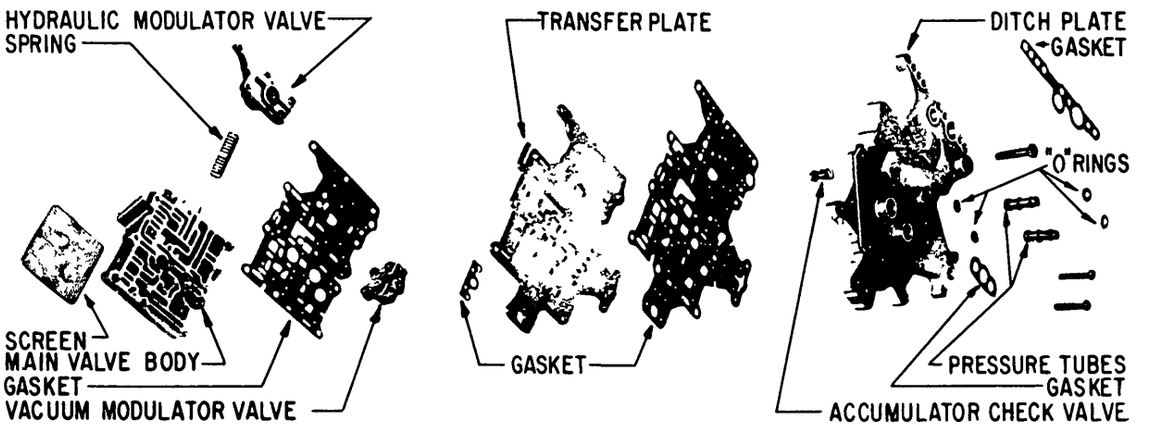
EARLY 1957 CONTROL VALVE BODY ASSEMBLY

1957-58 HYDRAULIC MODULATOR VALVE ASSEMBLY



EARLY 1957 CONTROL VALVE MAIN BODY ASSEMBLY

CONTINUED ON NEXT PAGE

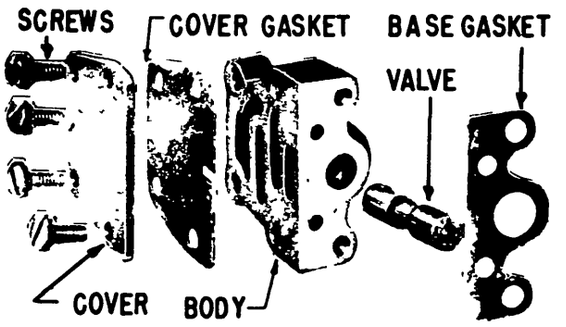


CHEVROLET TURBOGLIDE TRANSMISSION (C nt.)

spect valve bodies for cracks, scoring, or galling. Clean sump screen and inspect rubber by-pass valve.

Reassembly: Install the seven pipe plugs in valve body. Install detent ball and spring, then install new roll pin to retain detent ball and spring. Install inner and outer springs into accumulator piston and install this assembly into valve body *(NOTE - This is not the accumulator valve located in hydraulic modulator body).* Hold spring seat over springs and compress, then install retaining snap ring into groove in bore *(CAUTION - Do not confuse pressure regulator spring with accumulator outer spring. The pr ssure regulator spring is heavier with a free length f 3¼").* Install stator detent valve spring in valve body, then install detent valve with hollow end indexing over spring. Hold valve in and press roll pin to engage in groove in end of valve. Do not install pin too deep (end of spring should not touch bottom of groove). Check freedom of the assembly. Install accumulator control valve with tangs of valve inward, then install spring and plug. Compress spring by pushing in on plug, then install retaining pin. Install accumulator check valve spring onto accumulator check valve, then install assembly into respective hole in aluminum ditch plate (set aside for further assembly). *(NOTE* - Accumulator check valve spring is lightest spring in the valve assembly, and check valve has a hole in the center. Valve and spring are not interchangeable with other valves or springs in valve assembly). Install large hollow bolt through rear hole in ditch plate to aid in alignment of gaskets and parts. Install gasket on ditch plate, then install transfer plate. Invert valve body and install front and rear pump check valve, lubrication relief check valve and springs. Install gasket on valve body. Install transfer plate and ditch plate assembly on valve body, indexing holes in transfer plate with valves in valve body *(CAUTION - Mak sure that valve seats and gask ts ar not damag d).* Hold ditch plate down and start three bolts to hold plate to valve body *(NOTE* - On later valve bodies with ditch plate straps, install straps). Turn bolts completely down to overcome tension of valve springs. Install shortest bolt in center hole of valve body (this hole is used for the bottom bolt and for the screw retaining sump screen). *(NOTE* - Installation of wrong length bolt in this hole will prevent sump retaining screw installation). Install and tighten remaining bolts to 8-12 ft. lbs. Reverse valve body and install pressure regulator valve, washer, and spring into valve body. Install accumulator valve into hydraulic modulator valve body with piston boss facing down. Install both springs, then install spring cover with raised portion of cover away from spring, and compress (using a vise or "C" clamp) sufficiently to install snap ring *(CAUTION - Approximat ly 90 lbs. pressure is exerted by accumulator springs and care must be taken to prev nt damage to parts during valve installation).* Install modulator valve into hydraulic modulator valve body (valve can be installed either way). Place regulator valve spring into counterbore of modulator valve in modulator valve body, compress spring and install bolts. Install long bolt through valve body to ditch plate. Install vacuum modulator valve and gasket to valve body assembly and tighten screws. Install manual valve and sump screen. Install parking brake spring clip and bolt and tighten to 8-12 ft. lbs.

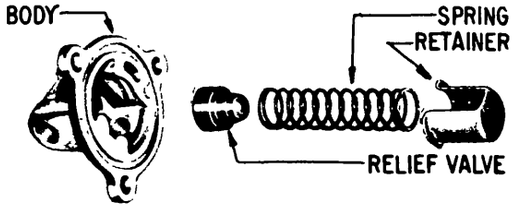
LATE 1957-58 TURBOGLIDE MAIN VALVE BODY ASSEMBLY (TYPICAL)



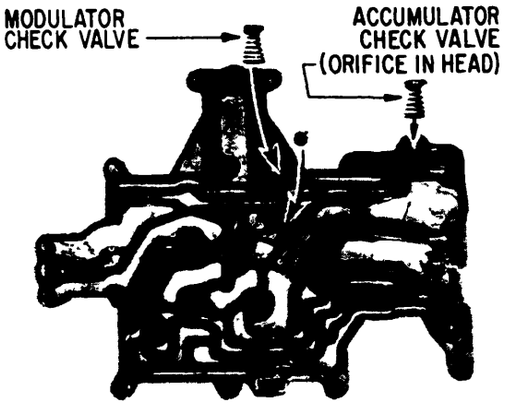
LATE 1957-58 TURBOGLIDE CONTROL VALVE ASSEMBLY (TYPICAL)

1958 MODELS

CONTROL VALVE BODY: Disassembly - Remove both oil pressure tubes (if they did not stay on support). Remove valve body screen and manual valve. Remove both gaskets between valve body and transmission case. Remove vacuum modulator valve body and gasket. Remove hydraulic modulator valve body. *NOTE - Hold valve body securely while removing bolts as this unit is spring loaded by pressure regulator valve spring.* Remove screw retaining parking pawl spring strut, then remove other valve body locating screw holding valve body to ditch plate. Invert valve body assembly and remove seven bolts holding ditch plate to valve body, then remove ditch plate reinforcing straps. Separate ditch plate from transfer plate and valve body, then remove gasket between ditch plate and transfer plate and remove transfer plate and gasket. Remove vacuum modulator accumulator check valve (with orifice in head) and remove vacuum modulator check valve (without orifice in head). Remove front and rear pump check valves, and lubrication relief valve, with their springs. *NOTE - Front and rear pump check valve springs ar*



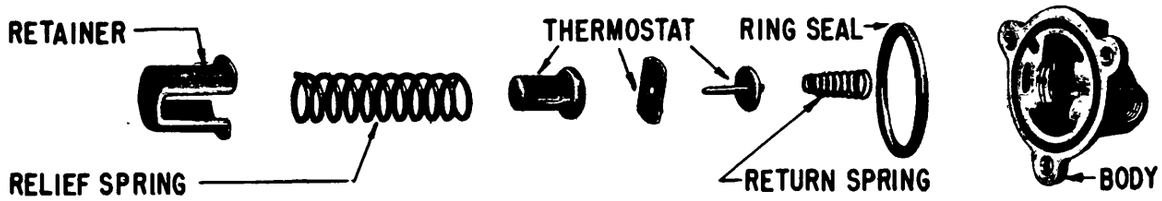
CONTINUED ON NEXT PAGE



1957-58 VACUUM MODULATOR VALVE ASSEMBLY

CHEVROLET TURBOGLIDE TRANSMISSION (C nt.)

interchangeable. Lubrication relief valve spring is heavier and is not interchangeable. The three valves are interchangeable. Remove manual control valve. Remove stator detent valve roll pin, then remove stator detent inner and outer springs and valve. *NOTE - Later valve bodies use a single heavier spring with the detent valve.* Remove accumulator valve snap ring, then remove spring seat washer, springs, and neutral accumulator valve. Remove detent ball roll pin, spring, and detent ball. Remove pressure regulator valve and spring seat washer. Remove roll pin, then remove accumulator passage plug. Remove seven socket head pipe plugs from valve body.



LATE 1957-58 THERMAL BYPASS VALVE

CHECK VALVE POSITIONS IN DITCH PLATE

Vacuum Modulator Valve - Remove cover screws and lift off cover and gasket, then remove valve and base plate. To reassemble, insert modulator valve into valve body, then install cover using a new gasket. Tighten screws evenly, then install a new base gasket.

Hydraulic Modulator Valve - Remove valve from valve body, then depress accumulator valve with a narrow hammer handle and remove retainer ring. Slowly release pressure on accumulator valve to prevent springs and valve from flying out, then remove valve and two accumulator springs. Remove accumulator valve retainer ring, and seat washer from opposite side of valve body. Inspect all parts for wear, nicks, or burrs, then

EARLY 1957 THERMAL BYPASS VALVE

reassemble as follows: Install one retainer ring in bottom of hydraulic modulator valve body and install seat washer. Place accumulator valve inner and outer springs in valve body and place accumulator valve on top of springs. *CAUTION - Do not confuse the pressure regulator spring with accumulator outer spring. Pressure regulator spring is heavier and shorter (.072" wire diameter with 3¼" free length).* Holding second retainer ring in snap ring pliers ready to install, depress accumulator valve deep into its cylinder with a hammer handle and install snap ring. *CAUTION - Be sure ring is fully seated before releasing pressure on accumulator valve.* Install hydraulic modulator valve. *NOTE* - Pressure regulator spring is not installed until final assembly of main valve body.

Reassembly: Install socket head pipe plugs in valve body, then install accumulator passage plug and secure with a roll pin. Install detent ball and spring in valve body, then install new roll pin to retain detent ball spring. Install neutral accumulator springs in accumulator piston and install piston into valve body. Hold spring seat over springs and compress, then install retaining snap ring into groove in accumulator piston cylinder wall. Install stator detent valve springs into valve body, then install detent valve with hollow end indexing over springs. *NOTE - Later valve bodies have a single, heavier spring with the detent valve.* Hold valve in and tap roll pin to engage in groove in end of valve. Do not install roll pin too deep (end of pin should touch bottom of groove). Check freedom of valve in bore. Install pressure regulator valve with spring seat washer installed in valve body, then install manual valve. Install front and rear pump check valves and lubrication relief valve. Refer to "Valve Location" illustration and install vacuum modulator valve (without orifice in head) in ditch plate, then install vacuum modulator accumulator check valve (with orifice in head) in ditch plate. *NOTE - This valve is closer to rear of plate from valve installed above.* Install large hollow bolt through rear hole in ditch plate to aid in alignment of gaskets and parts. Install gasket on ditch plate, then install transfer plate on gasket. Install transfer plate gasket on main valve body, then install transfer plate and ditch plate on main valve body indexing valves of valve body to holes in transfer plate and making sure valve seats and gaskets are not damaged. Hold ditch plate down and start three bolts to hold ditch plate to valve body, then turn bolts completely down to overcome spring tension of valves. *CAUTION - Be sur that b lt being installed at each location is the same l ngth as b lt pr viously removed from that locati n.* Install shortest bolt into center hole of valve body (this hole is common hole for bottom bolt and for screw retaining sump screen). *CAUTION - Installation of wr ng bolt at this l cati n will prevent sump screen r taining scr w installati n.* Position ditch plate reinforcing straps, then install and tighten remainder of bolts to 8-10 ft. lbs. Place pressure regulator valve spring into counterbore of modulator valve in hydraulic modulator valve body and compress spring to enable bolts to be installed. Install pressure regulator spring guide sleeve over end of pressure regulator valve spring (on units so equipped). Install long bolt through valve body to ditch plate, then, using a new gasket, install vacuum modulator valve body to valve body assembly and secure with two screws. Install sump screen. Install parking brake spring clip and bolt and tighten to 8-10 ft. lbs.

1957-58 MODELS

REAR EXTENSION HOUSING REAR OIL SEAL REPLACEMENT: Place extension housing on a wooden surface and remove oil seal using a cape chisel or punch (*CAUTION - Be careful not to damag aluminum case*). Using Installing Tool J-5154, install seal in extension housing.

► *EXTENSION HOUSING BUSHING NOTE: This bushing is precision bored in position and is not replaceable.*

TRANSMISSION REASSEMBLY

REASSEMBLY: 1) Install parking pawl and parking pawl shaft with "O" ring in transmission case. Index manual control lever into manual control rod and park lock pawl rod (bullet type), and secure with bolt and nut (*NOTE* - Shaft is serrated to permit installation in one position only). Install stator lever through control lever and install detent control lever plate, then install hairpin clip (*NOTE* - Stator lever is serrated to permit installation in one position only). Install parking lever bracket and tighten bolts to 7-9 ft. lbs.

2) Install rear race, needle bearing assembly, and front race on front of output shaft carrier. Install caged needle thrust bearing assembly on rear of output shaft (hold in place with lubricant). Install rear ring gear onto rear planet carrier and output shaft, using grease sparingly, to hold bearing in place. Install output shaft and rear ring gear assembly into case from the front. Install

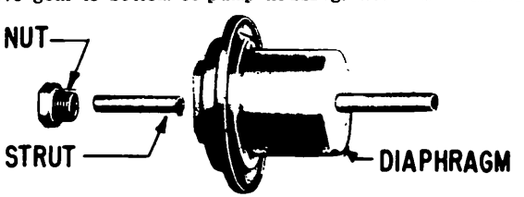
CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE TRANSMISSION (C nt.)

brake drive plate (composition) by indexing rear ring gear, then index brake reaction plate (aluminum) to case. Finally, index the other brake drive plate (composition) to rear ring gear.

3) Install forward cone on forward piston, then install forward cone ring over spring on forward piston, making sure that notches of ring fully engage outer tangs on edge of spring *(CAUTION - Be careful when placing spring on forward piston so that the indexing is proper for installation of ring to case and indexing of ring to the return spring).*

4) Install forward and brake pistons and support in case (outer forward cone ring may have to be tapped gently to compress spring in forward piston to provide enough space to install retainer. *(NOTE - Retainer must be s at d in groov in transmission case or failure may result, causing s rious damage to transmission).*



5) Install needle thrust bearing race over extension of front planet carrier, then install needle thrust bearing assembly over race. Install tanged washer on front end of planetary (use a small amount of lubricant to retain in position during assembly). Hold the neutral clutch assembly in one hand with the shaft pointing upward, then lift front planetary, with tanged washer installed, and index keyways on front planetary housing to cone lugs in neutral clutch assembly. *(CAUTION - Improper mating f th se parts will pr v nt transmission being assembl d).* After planetary assembly is installed, rest shaft of neutral clutch on bench and install freewheel sprag assembly over rear extension of planetary. Twist sprag assembly to mate sun gear to planetary gears. Install needle thrust bearing over extension of front planetary gear extending through freewheel unit.

► *REVERSE CONE RING SELECTION (For Proper Running Cl arance During Forward Drive Range Operation and Contact Area for Positive Holding in Reverse):* (1) Before installing the neutral clutch and freewheel units in the transmission case, temporarily install the reverse cone ring, cone, spring, and front pump and reverse piston assembly (be sure that cone is seated evenly in reverse cone ring). Secure front pump with at least four bolts. (2) Clamp a dial indicator onto side of transmission case, using an indicator tip 1¼" long, so that tip of indicator is against reverse piston (set tip on a flat area of piston to prevent slippage during piston travel). Set dial indicator at zero, then turn front end of transmission case downward, and, while watching dial indicator, apply air pressure to reverse piston passage in control valve mounting boss (second hole in boss, from control lever side of transmission case). If cone ring is within limits, indicator reading will be between .059-.085". If piston travel is over the high limit, repeat the test using a new **green** cone ring, Part No. 3740892, or a **blue** cone ring, Part No. 3740891, in that order. If travel is below the limits, repeat test, starting with the **green** cone first, then the **yellow** cone ring, Part No. 3740893.

6) Install neutral clutch and freewheel sprag assembly into case, twisting shaft to engage lugs of freewheeling assembly outer cam to forward clutch assembly mounted in transmission case (forward cam is loose and can be turned to align with lugs of freewheeling cam).

7) Turn transmission so input shaft is facing up and install reverse cone ring in case (tapered portion forward with tang fitted into case and oil return groove at bottom). Check for correct selective washer thickness as follows: With gasket installed on front pump assembly, install dial indicator on Tool J-6557 with indicator set at zero and touching contact arm on tool. Mount gauge and tool assembly to rear hub of front pump so that contact arm is resting on mounting flange of pump. Gauge several points around mounting flange and record the highest reading obtained. Remove gauge and dial indicator assembly and mount in transmission case over input shaft so that gauge arm contacts thrust washer pad of neutral clutch and front ring gear assembly. Record highest reading obtained at this point, then subtract reading from the reading taken on front pump assembly. The difference will indicate correct thrust washer thickness. Thrust washers are available in the following three sizes: .068" (Part No. 3727319), .085" (3727321), & .103" (3727320). Select the thrust washer which will provide a clearance of .008-.028".

8) Install four oil seal rings to extension on front ring gear hub. Install reverse cone into case, meshing tangs with slots in neutral clutch and front ring gear assembly. Install reverse cone spring into case. Install two guide studs, J-3361-10 in case to guide the pump assembly and avoid damage to oil seal rings. Install stator support gasket to case, then install square type seal ring on outer lip of stator support. Align tang of oil pump drive gear to bottom of pump housing. With front end of transmission case facing upward, index front pump on guide studs and carefully guide pump over oil seal rings on front ring gear hub shaft (tap housing lightly to fully seat in case). Remove guide studs and install capscrews retaining pump to case, and tighten to 15-18 ft. lbs.

1957-58 VACUUM DIAPHRAGM

9) Install converter assembly (driving lug of pump to mate with keyway of front pump drive gear) rotating converter as necessary to complete mating of splines.

► *CHECKING CAUTION: A minimum distance of ¾" from front of transmission case to front of converter at flang , measured with a straightedge assures that all parts ar properly engaged. If this distance is less, check transmission for improper assembly.*

10) Install Torus Holding Tool J-5384 in position and place transmission in a horizontal position. Turn output shaft to locate drive pin holes to top of transmission, and install drive pins *(CAUTION - Make sure that drive pins do not fall out of transmission during assembly).* Position rear pump output shaft indexing drive gear to drive pin. Install bolts through pump into rear of case and tighten to 7-9 ft. lbs. Install square seal ring over pump.

11) Install thermal by-pass and tighten to 7-9 ft. lbs., and install vacuum diaphragm outside of case along with vacuum modulator strut and attaching nut. Install "O" rings in support and then install "O" rings on oil pressure tubes in support (tapered end of support) through case, making sure that seal rings are seated. Install valve body gaskets, using a small amount of lubricant to retain gaskets in position for assembly.

12) Place stator control or detent lever in "down" position and install valve body in case, guiding detent plate into groove, manual lever to manual valve detent valve, and carefully pick up manual valve, oil pressure tubes and vacuum modulator strut. Install special drilled bolt at rear of valve body to rear case (hole in bolt carries lube pressure to drilled passage in case to output shaft, from valve body). Tighten hollow bolt to 18 ft. lbs. Install remaining bolt in valve body and tighten to 8-10 ft. lbs.

13) Index spring in parking pawl lock, then index into clip on rear bolt of valve body. Install speedometer gear on output shaft with Tool J-5814. Install in extension housing and install extension housing on transmission case. Tighten bolts to 23-26 ft. lbs.

► *EXTENSION HOUSING INSTALLATION NOTE:* After tightening extension housing bolts, install universal joint yoke on output shaft and rotate freely. If yoke is tight, remove rear extension and tap rear oil pump body with plastic hammer to center output shaft with rear extension bushing and seal.

14) Install driven speedometer gear in extension housing and install transmission oil pan gasket and oil pan.

CHEVROLET TURBOGLIDE TRANSMISSION

Chevrolet Pass. Cars (1959-60)

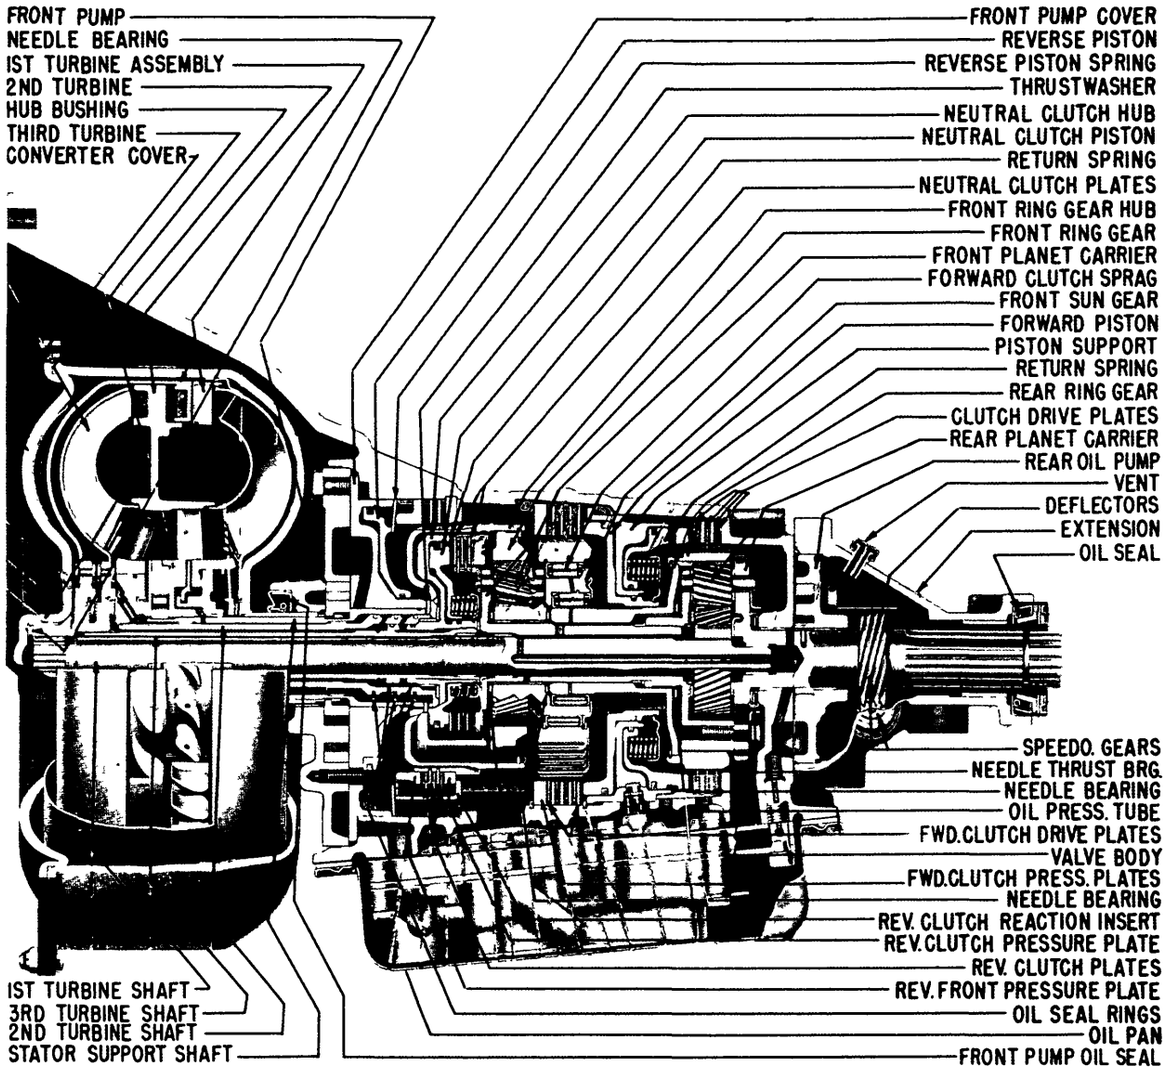
►CHANGES, CAUTIONS, CORRECTIONS

►*1959 TURBOGLIDE CONVERTER COVER INSTALLATION NOTE & ALIGNMENT MARK PRODUCTION CHANGE:* Later production converter covers and converter pump housings do not have the 5/32" hole in outer flange of both parts. To align these parts at reassembly, index the identical notch in outer rim of both cover and converter pump housing.

►*TURBOGLIDE REVERSE CLUTCH PLATE REPLACEMENT CAUTION:* It is important that when a reverse clutch plate is installed, a new reverse clutch piston return spring be installed at the same time. *NOTE* - The old spring may appear to be normal but will be "dished" in the opposite direction to a new one. This condition will result in clutch failure.

►*1960 TURBOGLIDE HYDRAULIC MODULATOR VALVE BODY PRODUCTION CHANGE & 1959-60 SERVICE REPLACEMENT NOTE:* A new hydraulic modulator valve body, Part No. 3779625, without the vacuum modulator accumulator valve is being used in production and may be used for service replacement on 1959-60 transmissions to replace the former valve body, Part No. 3759834. Early and later type valve bodies are interchangeable and either may be used for service.

►*STARTING ENGINE BY PUSHING CAR:* Place control lever in "N" (Neutral) range until car reaches 25-30 MPH. Turn key on and move control lever to "GR" (Grade Retarder) position. After engine starts, move control lever to "N" (Neutral) for engine warm-up. Towing is not recommended to start car.



►*TOWING TURBOGLIDE CARS:* Cars must not be towed with rear wheels on ground except with transmission in "N" (Neutral) position and must not be towed in excess of 30 MPH. If car is to be towed a long distance, drive shaft should be removed. *NOTE* - If car has been damaged and transmission cannot be placed in "N" with selector lever, disconnect long rod from idler lever on left side below mast jacket, then pull lever on transmission toward front of car as far as it will go. Move lever toward rear of car from the forward position to the third detent which is "N" (Neutral) position.

DESCRIPTION: Design is similar to 1957-58 Turboglide transmissions except as noted below.

Clutches: Multiple plate type clutches have replaced the former "cone" type clutches at the forward and reverse clutch locations.

Second Turbine: A five spoke second turbine is being used. The second turbine shaft is heavier and a bushing has been added to prevent interference between second turbine shaft and the stator shaft bore.

Main Valve Body: Valve body reinforcing strap, accumulator passage plug, and the two check valves in modulated oil circuit have been eliminated. A second spring and a spring cap between the pressure regulator valve and the hydraulic modulator valve have been added. A single short heavy spring replaces the two springs formerly used with the hydraulic modulator accumulator.

CHEVROLET TURBOGLIDE TRANSMISSION (SECTIONAL VIEW)

Front Planetary Gearset: Six planet gears replace the three formerly used. *NOTE - Because of pinion alignment, the front planetary set is serviced only as a unit. DO NOT attempt disassembly.*

LUBRICATION

Check oil level every 1000 miles. *NOTE - Draining and refilling of transmission is not recommended other than for transmission repairs.*

Capacity - 2 quarts (refill), 9½ quarts (after overhaul).

Recommended Oil - Use Automatic Transmission Fluid Type "A", Suffix "A". If this type fluid not available, use Automatic Transmission Fluid Type "A".

Checking Fluid Level: With transmission at normal operating temperature, transmission selector lever in "N" (neutral), check oil level on dipstick located in engine compartment on right side.

Draining & Refilling: *NOTE - Draining & refilling of transmission is not recommended other than for transmission repairs.* Remove drain plug (early cars), filler tube (later cars). To refill, replace drain plug or filler tube, then install 2 qts. of recommended fluid. Start engine and allow to run a few minutes at idle speed, then check oil level. If necessary, add oil to bring level up to "FULL" mark on dipstick. *NOTE - If torque converter was drained, approximately 9½ qts. of fluid will be required to fill transmission and converter.*

CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE (C nt.)

LINKAGE ADJUSTMENT

►*THROTTLE LINKAGE ADJUSTMENT NOTE: See CARBURETOR on car model pages.*

Manual C ntr l Linkag : Place selector lever in "D" (Drive) position, then disconnect swivel on shift control rod at its attachment to shift control lever on mast jacket in engine compartment. Position shift lever on transmission in "D" (Drive) position (second detent forward, from full rear position). Adjust swivel on shift control rod for free entry into shift lever on mast jacket. Secure swivel nut attachment to mast jacket shift lever, then test transmission shifts in all ranges.

N utral Saf ty Switch: Place selector lever in "N" (Neutral) and loosen screws attaching neutral safety switch retainer. While holding ignition switch in "START" position, adjust position of switch until engine turns over. Hold switch in this position and tighten retainer screws. Check adjustment by testing for cranking in both "N" (Neutral) and "P" (Park).

TROUBLE SHOOTING

DRIVE POOR AT LOW SPEEDS (NO REVERSE, GRADE RETARD NORMAL): Inner overrun clutch assembled backwards.

NO DRIVE EXCEPT IN GRADE RETARD: Both overrun clutches assembled backwards.

NO DRIVE EXCEPT IN GRADE RETARD AND REVERSE: Outer overrun clutch assembled backwards. Forward and neutral clutch not applied due to severe leakage in forward clutch hydraulic circuit.

CAR DRIVES VERY SLIGHTLY IN NEUTRAL (REVERSE NORMAL): Neutral clutch not released.

CAR DRIVES NORMAL IN NEUTRAL AND DRIVE AT LOW SPEEDS (NO REVERSE): Forward clutch not released.

TRANSMISSION WILL NOT SHIFT TO HIGH STATOR ANGLE: Stator control linkage out of adjustment. Converter charging pressure low for one of the following reasons: (a) Leakage which will reduce line pressure enough to cause pressure regulator valve to shut off converter in line. (b) Leakage in converter circuit. (c) Stator control pressure leaking to converter out across front oil seal ring or second oil seal ring on second turbine shaft.

UNABLE TO PUSH START: Rear oil pump drive pin broken or missing.

CLUTCH SLIPPAGE ON WIDE OPEN THROTTLE STARTS: Low oil pressure due to leakage (especially check forward pressure tube "O" ring). Mechanical interference which will prevent forward or neutral piston to fully apply. Neutral or forward clutch facing bond failure.

SECOND TURBINE SEAL RING LANDS INTERFERING WITH I.D. OF STATOR SHAFT: Case locating dowels on engine or dowel holes in case misaligned. Check by indicating front pump bore in case from crankshaft.

GRADE RETARD SLOW TO APPLY: Control linkage out of adjustment, preventing manual valve getting into grade retard position. Leakage to grade retard clutch (check pressure tube "O" ring seal and other sources). Mechanical interference in grade retard piston. Glazed grade retard plates (check neutral clutch for release). If neutral clutch does not release during grade retard, grade retard plates can be damaged.

NO DRIVE, REVERSE NORMAL, NO GRADE RETARD: Reverse clutch not disengaged.

GRADE RETARD BRAKES VIOLENTLY, STATOR PRESSURE READS HIGH ON CHECKING: Vacuum hose disconnected.

SHIFTS FROM STANDSTILL VERY SLOW: Check linkage to ascertain that shift lever is positioned by transmission detents. Accumulator control valve stuck closed. Leakage in hydraulic system (Check pressure tube "O" rings and other seals and gaskets).

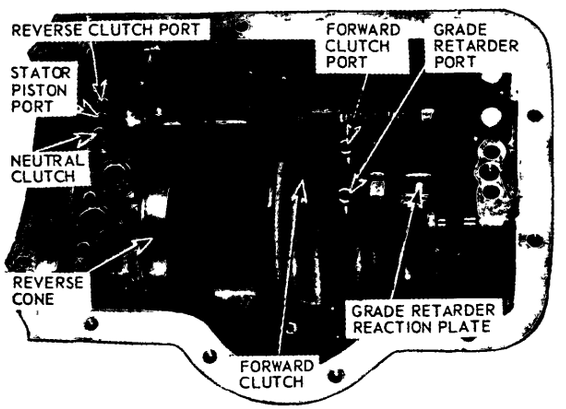
SHIFTS FROM STANDSTILL VERY FAST AND HARSH: Accumulator control valve spring too strong or valve stuck open.

TESTING

►*TESTING CAUTION: Before testing transmission, check oil level and bring it to the "FULL" mark on dipstick (See LUBRICATION above). Warm transmission to normal operating temperature as outlined below. Adjust engine idle speed to 425 RPM with transmission selector lever in "D" (Drive) range. Adjust throttle linkage (see CARBURETOR on car model pages).*

►*TESTING CAUTION: Do not stall-test Turboglide Transmission.*

TRANSMISSION WARM-UP: (In Shop) – Connect tachometer to engine, set parking brake and start engine. Place selector lever in "D" (Drive) range and adjust carburetor idle speed to approximately 750 RPM. Operate engine at this speed for 15 minutes, then readjust engine idle speed to 425 RPM with transmission selector lever in "D" (Drive) range.



On Road – Drive car for approximately 5 minutes with frequent starts and stops. Make sure engine idle speed is 425 RPM with transmission selector lever in "D" (Drive) range. Check fluid level (see LUBRICATION above). *CAUTION –* If fluid level too high, lower the level to "FULL" mark, then drive car five minutes to work bubbles out of fluid.

PRESSURE TEST: Road - Connect pressure gauge to test point on left side of transmission case and connect a tachometer and a vacuum gauge to engine. With engine and transmission at normal operating temperature and oil level in transmission at "FULL" mark, proceed as follows: Place selector lever in "D" (Drive) position and bring car speed to approximately 30 MPH. Push accelerator to wide open position. Engine speed should increase to 700-900 RPM if stator is functioning and the pressure should rise to 190-210 lbs. at 3" manifold pressure. *NOTE - At any car speed, with foot off throttle, pressure gauge should read 80-90 lbs. with 18-25" of engine vacuum (pressures in "R", reverse, should be the sam as in "D", drive).* With selector lever in "D" (Drive) and at a road speed of 45 MPH, foot off throttle, pressure gauge should read 80-90 lbs. Place selector lever in "GR" (Grade Retarder) range at 45 MPH, and pressure should drop to zero. *NOTE - Engine speed may drop momentarily (during manual shift from "D" to "GR") and then the Grade Retarder clutch will apply and the engine speed will increase.*

AIR PRESSURE TESTS (WITH TRANSMISSION IN CAR): Drain oil from transmission and remove converter cover pan, transmission oil pan, and main valve body. Install oil pressure tubes in Forward Clutch and Grade Retarder apply ports (see illustration). Use Tool J-4353-1 and an air source of 100 lbs. pressure. Proceed as follows for the five air pressure checks:

Reverse Clutch: Apply pressure to reverse clutch port (see illustration) and visually check that reverse cone moves rearward. Listen for air leaks. If reverse cone does not move, determine whether front pump-to-transmission case gasket is incorrectly installed and blocking oil passages, or if reverse piston is cocked or bound. If air leaks are heard, check for damaged front pump-to-transmission case gasket or for damaged seals in reverse piston.

Stator Piston: Apply air to stator piston port (see illustration), and listen for air leaks. If air leaks are detected, check for a mispositioned or damaged front pump-to-

TRANSMISSION AIR TEST POINTS

transmission case gasket, broken or warped seal rings on second turbine shaft, defective stator piston seal, or damaged or worn brass seal in the inside diameter of stator support. Should it be determined that stator support brass seal is at fault, the stator support must be replaced as brass seal cannot be replaced separately.

Neutral Clutch: With air applied to neutral clutch port (see illustration), listen for application of clutch and air leaks. If no clutch application is heard, determine if the front pump-to-transmission case gasket is incor-

CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE (Cont.)

rectly positioned and blocking oil passages; otherwise disassemble neutral clutch and check for a locked-up or binding condition. If air leaks are heard, possible causes are a torn or distorted front pump-to-transmission case gasket, warped or broken oil seal rings on second or third turbine shafts, defective brass seal in the inside diameter of second turbine shaft. If brass seal is faulty, replace front ring gear hub and shaft assembly.

Forward Clutch: With oil transfer tube installed, apply air pressure to tube and observe that forward clutch applies. Listen for air leaks. Failure of clutch to apply can be the result of a wedged forward piston or Grade Retarder piston, probably caused by cocked piston "O" rings. A blockage of oil feed orifice in forward and brake piston support could also prevent clutch application. The first place to check if air leaks are found is the "O" ring seals on oil pressure tube in forward clutch port; otherwise, check forward piston-to-support seals.

Grade Retarder Piston: Apply air to grade retarder piston port with oil pressure tube installed (see illustration). Check Grade Retarder application by watching for movement of grade retarder reaction plate which will occur as the brake plates are forced against it by piston moving backward. If grade retarder piston does not move, check for cocked "O" ring seals in both the grade retarder and forward pistons or check for blocked orifice in piston support. Leakage could only occur at either the oil pressure tube "O" ring seal or brake piston "O" ring seal.

TRANSMISSION REMOVAL & INSTALLATION

REMOVAL: 1) Raise car on a hoist *(see "Jacking & Hoisting" in Suspension & Wheel Alignment Section)*, then proceed as follows:

2) Drain oil from transmission *(see "Draining & Refilling" above)*, then disconnect oil cooler lines and speedometer drive cable fitting at transmission (tie lines out of way). Remove crankcase ventilator tube clamp bracket bolt from transmission.

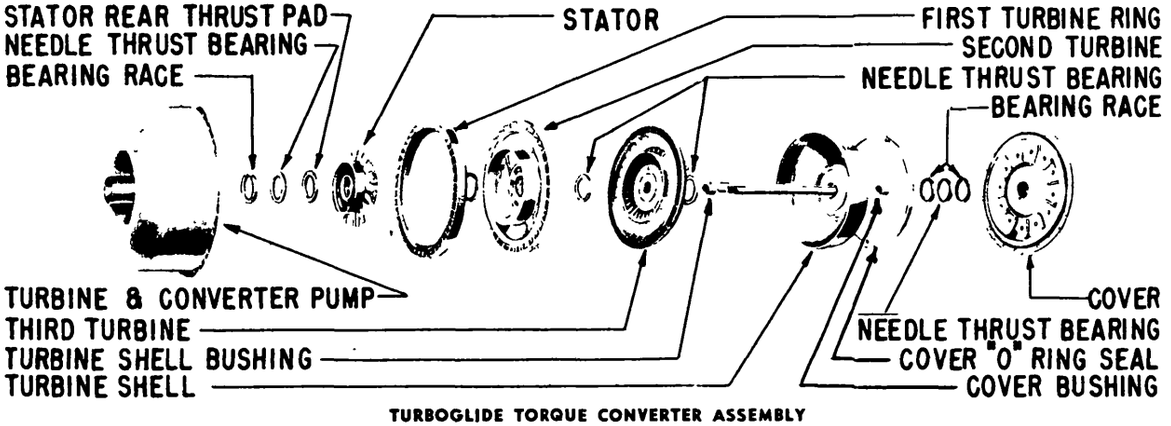
3) Remove vacuum modulator hose from vacuum modulator and from clamped attachment at side of transmission. Disconnect manual and throttle valve control lever rods from transmission, then disconnect propeller shaft from transmission.

4) Install suitable transmission lift equipment to jack or other lifting device and attach on transmission. Disconnect engine rear mount on transmission, then remove transmission support crossmember. *NOTE - Crossmember is attached to frame bracket at upper attaching holes. Use care to remove any shims which may be installed between extension mounting boss and crossmember. It is very important that exactly the same number of shims be installed when transmission is replaced in car.* Remove flywheel cover and scribe a line to establish relationship between flywheel and converter, then using a jumper to turn engine, remove flywheel-to-converter attaching bolts.

5) Lower rear of transmission slightly so three upper transmission housing-to-engine attaching bolts can be reached using a universal socket and approximately a 39" extension. Remove upper bolts. *CAUTION - Care must be taken not to lower rear of transmission too far as distributor housing may strike firewall.*

6) Support engine at oil pan rail with a jack, then remove remainder of transmission housing-to-engine attaching bolts. Remove transmission by moving it slightly to rear and downward, then remove from beneath car. *CAUTION - Keep front of transmission upward to prevent converter from falling out. Install Converter Holding Tool J-5384 immediately after transmission removal.*

INSTALLATION: 1) Mount transmission on lifting device. then remove Converter Holding Tool J-5384. then raise transmission into place and install transmission case-to-engine upper mounting bolts. Install lower and side bolts. *CAUTION - Be careful that converter does not move forward causing disengagement of pump hub drive slots from lugs of front pump drive gear.*



2) Remove support from beneath engine, then raise transmission into position. Connect body ground strap.

3) Through transmission underpan opening, align as closely as possible the "white" flywheel balance mark stripe and the "blue" painted stripe on end of converter housing. If scribed during removal, align scribe marks on flywheel and converter cover. Install converter-to-flywheel attaching bolts and tighten to 15-20 ft. lbs.

4) Reinstall transmission support crossmember. *NOTE - Two sets of holes are provided for attachment of crossmember to frame as follows: Lower holes are to be used with Powerglide. Upper holes used with Turboglide.* Be sure to reinstall exactly the same number (and thickness) of shims between extension mounting boss and crossmember as were removed. *NOTE - These shims maintain correct drive line angle.*

5) Remove transmission lift equipment and support, then connect propeller shaft to transmission. Connect manual and throttle valve control linkage to transmission. Connect oil cooler lines, vacuum modulator hose and speedometer drive cable to transmission. Reinstall oil filler tube and fill transmission. *See LUBRICATION above.*

6) Adjust all transmission linkage. *See LINKAGE ADJUSTMENT above.*

TURBOGLIDE TORQUE CONVERTER ASSEMBLY

TRANSMISSION DISASSEMBLY

►*TRANSMISSION OVERHAUL CAUTION: Before disassembling transmission, clean outside of case thoroughly to prevent dirt getting into transmission parts. As each part is removed, clean it with cleaning solvent and blow dry with air. DO NOT USE WIPING CLOTH (which may leave lint on parts).*

DISASSEMBLY (Into Major Units): 1) Remove converter assembly from transmission *(CAUTION - Prevent damage to converter output shaft during removal as the output shaft bushing may be misaligned which would mak replacement of torus shell and shaft ass mbly necessary).* Remove oil pan and gasket. Remove capscrew and retaining clip holding speedometer gear housing in extension and remove housing. Remove extension housing from transmission, noting seal ring in rear pump body. Remove speedometer gear oil deflector, then remove speedometer drive gear from output shaft with Tool J-5814. Remove oil pump, seal ring, and driven gear, then remove pump drive gear, drive pin, and wear plate from output shaft. *CAUTION - When gear is removed, drive pin can fall out if hole is on bottom of shaft and shaft is horizontal.*

2) Remove parking pawl spring and remove four bolts retaining valve body assembly to case *(NOTE - All three units of valve body will come off as an assembly).* Bolts are two different sizes. Rear bolt is hollow to permit oil pressure to valve body.

3) Remove two oil pressure tubes between valve body assembly and case *(NOTE - Tubes are interchangeable and the "O" ring seals are the same).* Remove vacuum modulator plunger.

4) Place transmission with shaft facing upward, then remove seven front oil pump bolts. Remove front oil pump and reverse piston assembly (includes stator shaft and support, square seal ring and gasket), using Tool J-6585. *NOTE - There are two threaded holes to mount puller, Tool J-6585, in front pump body.* Remove reverse piston spring, neutral clutch and front ring gear assembly and reverse front pressure plate, three drive

CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE (C nt.)

plates, and two steel reaction plates by grasping the second turbine shaft and pulling out of case. Separate the spring and clutch pack from neutral clutch unit. *NOTE - The reverse front pressure plate is selective. The selective washer on front ring gear hub of neutral clutch unit will be removed during disassembly of neutral clutch and front ring gear.*

5) Remove reverse rear pressure plate and reverse clutch reaction insert. Remove front planet carrier thrust washer, front planet carrier and neutral clutch hub assembly. Remove the race, needle bearing, and thrust ring from carrier extension. Remove front sun gear freewheel assembly (overrunning sprag clutch unit) and needle thrust bearing. Remove forward clutch retainer ring from transmission case by prying out with a screwdriver.

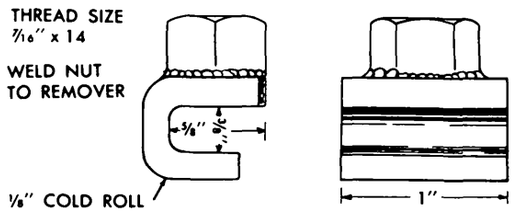
6) Remove forward clutch pack consisting of a pressure plate, four drive plates and four steel reaction plates. Remove retainer ring securing forward and brake piston, and support by prying out at case slots with a screwdriver (note position of ring gap in case).

7) Remove ring gear assembly and the forward and brake piston and support assembly as a unit by grasping the ring hub to extract from case. Separate the two assemblies. Remove rear planet carrier assembly and race, needle bearing and race on hub of carrier. The front race may adhere to rear ring gear previously removed. Also remove caged needle bearing from rear of carrier or case.

8) Remove grade retarder plates which consist of four steel reaction plates (two thicknesses) and three drive plates.

9) If required, remove remainder of case components as follows: Remove "C" retainer from shaft at inner throttle valve lever and remove throttle valve control outer lever assembly with shaft. Throttle valve inner lever will be free of shaft and should be removed.

10) Loosen screw and nut securing parking lock and range selector inner lever to outer lever and remove both levers. If necessary, disassemble parking lock actuator rod from inner lever by removing "C" retainer. Remove parking lock bracket, parking lock pawl shaft, "O" ring seal and pawl. Remove bypass valve assembly and square seal ring. *CAUTION - Spring under cover in bypass valve is under tension and care should be tak n when cover removed.*



11) Remove vacuum modulator assembly by unscrewing from case, then lift out vacuum modulator and remove gasket.

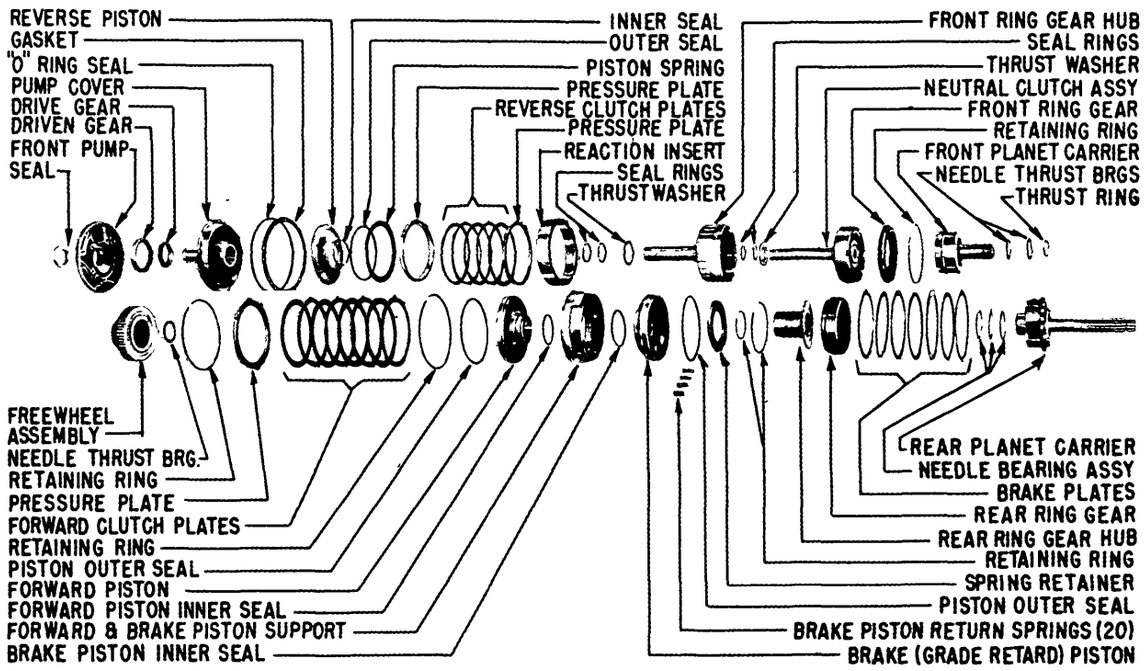
CONVERTER OVERHAUL

►*OVERHAUL NOTE: After removal from case, overhaul sub-assemblies or units as follows:*

TORQUE CONVERTER (Disassembly): Mount converter in a support to avoid damage to turbine output shaft. *(CAUTION - Scribe a mark on converter housing and cover for alignment and balance).* Remove bolts from cover, then remove cover from converter pump. Remove square seal from cover. Remove first, second, and third turbines as an assembly. Remove stator assembly. Remove stator rear thrust pad, needle thrust bearing and thrust bearing race.

Turbin - Place converter turbine assembly on bench and drive out three drive pins enough to remove first turbine from turbine shell (a small punch should be used to drive pins through the inside of first turbine shell to protrude from first turbine ring). Remove first turbine ring from turbine shell with Tool J-6585, and first turbine ring remover (see illustration). *(NOTE - First turbine ring remover must be fabricated locally).* Remove second and third turbine from turbine shell.

FIRST TURBINE RING REMOVER TOOL



Stator - Remove clutch head retaining screws and front thrust pad, then remove stator freewheel cam, rollers and springs. Remove stator freewheel race, then remove stator blade front carrier by pushing on rear extension of front carrier. Two dowel pins hold the front carrier from turning. Remove 20 stator blades, stator piston and retaining ring, then remove stator piston from blade rear carrier and remove ring from piston *(CAUTION - Be careful not to break cast iron seal ring on stator piston).*

Inspection: Wash all parts in cleaning solvent and blow dry with air *(CAUTION - Do not us rags to dry parts).* Inspect converter pump hub outer surface, and pump thrust washers for galling or scoring. Check converter pump vanes and turbine vanes for looseness or damage. Inspect turbine hubs, turbine thrust washers, stator race and cam rollers for galling or scoring. Inspect converter cover bushing for galling, scoring, or excessive wear. Inspect cam springs for distortion. Inspect stator for galling or scoring and for loose vanes or damage. Inspect loose needle thrust bearing assembly and races for damage.

Converter Cover Bushing Replacement: Use precision type converter cover bushing, Part No. 3737261 for field service replacement (this bushing does not require reaming). Install bushing as follows: Remove thrust washer, needle thrust bearing assembly with a sharp instrument. Remove bushing with a chisel or sharpened tool, taking care not to damage thrust surfaces in bottom of bushing hole. Place new bushing on pilot end of converter cover bushing replacer, Tool J-6583, and press bushing into place. Replace thrust washer and needle thrust bearing assembly

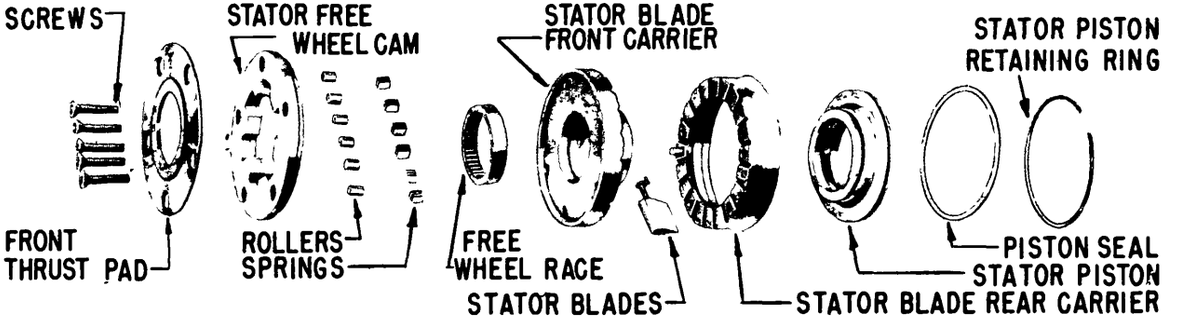
►***FIRST TURBINE HUB THRUST (NEEDLE OR SOLID TYPE) BEARING NOTE: Either a needle type or a solid type bearing is used. Removal and installation procedures are similar.***

First Turbine Hub Bearing or Bushing Replacement: Remove needle or solid bearing, then remove bushing with a sharp cape chisel, being careful not to strike turbine hub. Use Tool J-6561 and pilot the bushing on end of tool, then press into hub of first turbine. *NOTE - Bushing is precision type and does not require reaming.* Install a new needle bearing assembly (or solid bearing) with Tool J-6561 (end opposite that used for bushing). *CAUTION - Do not cock b aring during installation.*

CHEVROLET TURBOGLIDE INTERNAL COMPONENTS (EXPLODED VIEW)

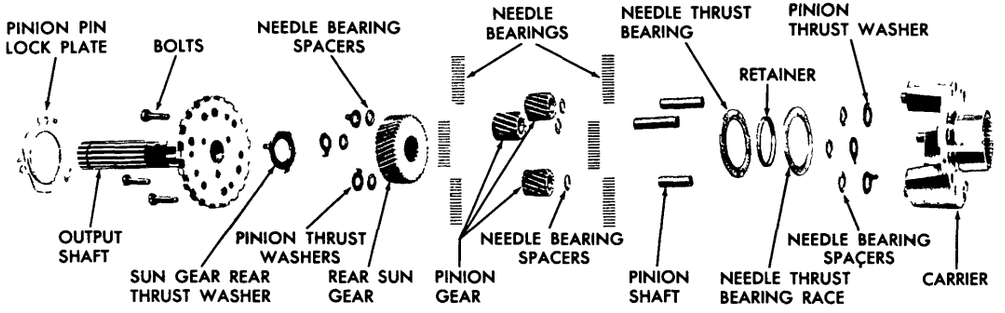
CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE (C nt.)



Sec nd & Third Turbin Hub Bearing R plac ment: These bearings are replaced in the same manner as for first turbine. *NOTE - All three turbines use the same bearing assembly.*

Reassembly: Stator - Install cast iron seal ring in stator piston and install stator piston in rear blade carrier, being careful not to break cast iron seal ring. Install stator piston retaining ring and install the 20 stator blades. *(NOTE - Trailing or sharp edge of blades should point downward after installation in stator. Neck of stator piston must be pushed fully through rear carrier to install stator blades).* Install stator front blade carrier, indexing the dowel pins in holes in rear blade carrier. Install stator freewheel cam in stator front blade carrier, aligning holes for retaining screws. Install freewheel race, springs and cam rollers with springs in large end of ramp slots of freewheel cam. Install front thrust pad and retain with five screws. Tighten screws to no more than 3-4 ft. lbs.



Turbine - Install needle thrust bearings with Tool J-6561, in the three turbines (needle thrust bearing assembly is the same for each of the three turbines). Support third turbine with suitable bushing while installing thrust bearing *(CAUTION - Do not strike or drive needle bearing on thrust surface. The needle bearing should be installed only by applying force to outer edge of bearing).* Install third turbine in turbine shell with vanes up. Install second turbine in turbine shell with flange upward. Align balance marks, then install first turbine inner ring with inner flat surface facing up in turbine shell. Locating three drive pins in shell with their respective holes in the inner ring can be accomplished with a small drift having the diameter of the pin. Complete installation by seating pins in place with a small "C" clamp.

Converter - Install steel spring ring into thrust bearing opening in pump and invert pump and converter assembly on stand and install needle bearing race (thinner washer) in pump. Install needle bearing assembly in pump, then install stator rear thrust pad (heavier of two washers). Install stator assembly into pump with bolts on stator facing up. Mount pump on stand face up, and index converter turbine shaft through pump and stator assembly. Install new square ring seal on converter cover. Place thrust washer, needle bearing, and another thrust washer on face of hub. Install converter cover and align balance marks on converter cover and pump. Install bolts on each side of scribe mark, omitting each fourth bolt, then tighten nuts finger tight. Tighten converter bolts as follows: Tighten every third bolt to 8-12 ft. lbs., (in rotation). Tighten remaining bolts to 8-12 ft. lbs., (in rotation), then tighten all bolts to 13-18 ft. lbs., (in rotation).

PLANETARY UNITS: R ar Unit Disass mbly - Bend tabs of pinion lockplate away from bolt heads, then mark or scribe edges of carrier and output shaft flange for correct reassembly. Back out bolts so approximately ½" of bolt length extends toward output shaft, then with output shaft held downward, support assembly in a press so as to press on the extended bolts. Using a suitable tool, press on sun gear with the press arbor until carrier separates from output shaft. Remove bolts to free carrier. *NOTE - Pinion shafts will normally remain in output shaft. If pins hang at start of separation of carrier from output shaft, drive pins out of carrier from carrier side so that they may all remain in output shaft. Be careful not to lose any of the planet pinion needle bearings.* Using a drift, tap edge of lock plate to free it from grooves in pinion shaft and remove lockplate. Install output shaft (containing pinion shafts and remaining gear set components) in a vise with shaft pointing downward, then remove needle bearing assembly, needle thrust bearing race, sun gear and sun gear thrust washer. *CAUTION - Thrust washer retainer should not be removed unless replacement is required.* Place a dummy shaft (old pinion or a wooden dowel the same size as pinion shaft) on end of pinion shaft and slide a knife blade between lower thrust washer and pinion shaft holder. Lift up on knife and slide lower pinion thrust washer, pinion with needle bearings, and upper pinion thrust washer onto dummy shaft. Remove remaining pinion assemblies in the same manner. *NOTE - Pinion shafts may be removed, if necessary, by knocking them out of output shaft with a drift (drive toward output shaft on nd opposite lock plate groove).*

VARIABLE STATOR ASSEMBLY

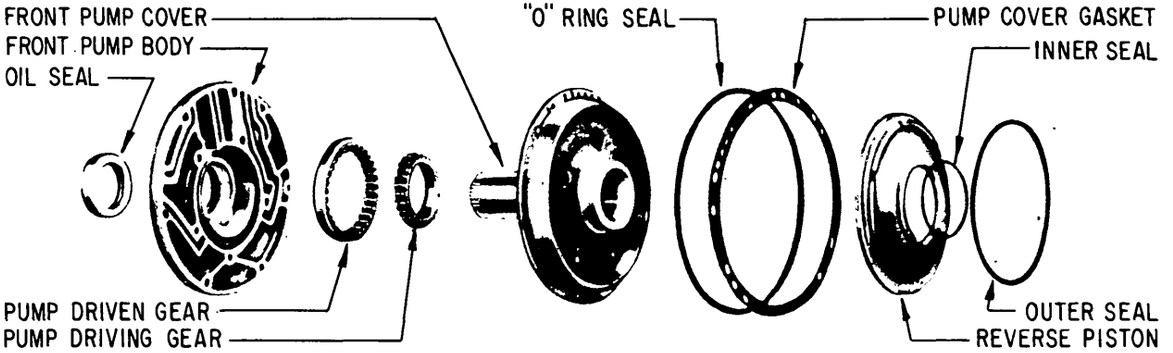
REAR PLANETARY GEAR SET

Insp ction: Wash all parts in solvent and blow dry with air. Check planetary pinion bears and sun gear for nicks or other tooth damage. Check thrust washer for wear or scoring and replace all worn or damaged parts. *NOTE - The output shaft bushing is precision bor d during assembly and is not replaceable.* Inspect planetary needle bearings closely and if excessive wear shows, replace all bearings in that pinion. Check pinion shafts and replace if worn (install new pinion shafts in output shaft half of the assembly).

Rear Unit Reassembly: Install locking plates so they fully seat in grooves in pinion shafts, then install output shaft in vise, shaft downward, using a dummy shaft. *CAUTION - Two b aring arrang m nts may be found in production transmissions. In one, 17 needle bearings separated by a spac r are installed in each end of the pinion. In other installations a single row of 17 longer type bearings are installed in ach pinion, eliminating the use of a spac r.* When assembling bearings, use petroleum jelly to hold bearings in place. Install pinion thrust washer over pinion shaft with tang indexed to small lock hold in output shaft. Index dummy shaft with pinion gear assembly on pinion gear shaft and slide pinion gear assembly over shaft. Repeat operation for remaining pinion assemblies. Install sun gear rear thrust washer into output shaft with tang of thrust washer positioned downward and into lock hole in output shaft, then install sun gear. *NOTE - If thrust bearing retainer replacement was necessary, press a new retainer into carri r until retainer bottoms.* Install sun gear needle thrust bearing race and thrust bearing assembly in rear planet carrier (use petroleum jelly to

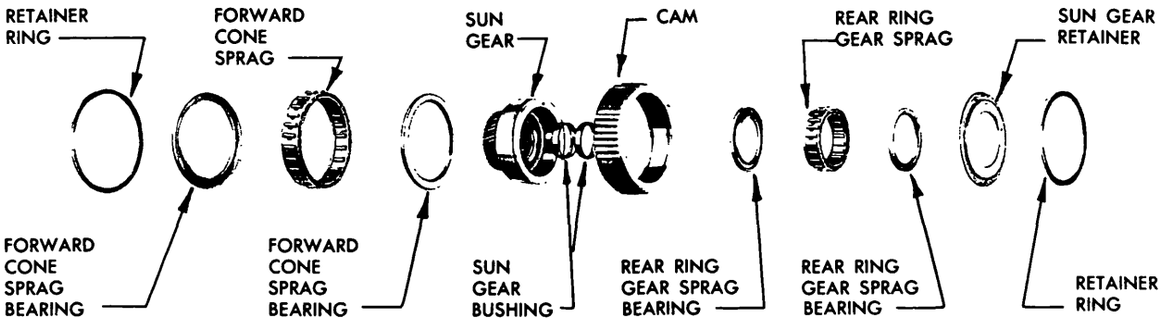
CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE (C nt.)



keep pieces located during assembly). Install pinion thrust washers with tange upward. Align scribe marks on carrier with marks on output shaft and insert carrier dowels into respective holes in output shaft. While assembling carrier to output shaft, align tangs of thrust washers to lock holes in carrier. With output shaft downward, press on carrier with arbor press until halves are are fully together. Install three bolts and tighten to 18-22 ft. lbs. Check end clearance of planet gears between thrust washer and flange. *CAUTION - Reading must be taken in this area.* If clearance is greater than .006-.030" and thrust washers are not worn, check to see that carrier has been fully pressed to output shaft. When correct clearance has been obtained, bend lockplate tabs onto bolts.

Front Unit & N utral Clutch Hub: *NOTE - Component parts of this unit are not serviced. If worn or damaged, the entire carrier unit must be replaced as an assembly.* Inspect this unit in same manner as for rear unit (above). End clearance of planet gears should be .006-.030".

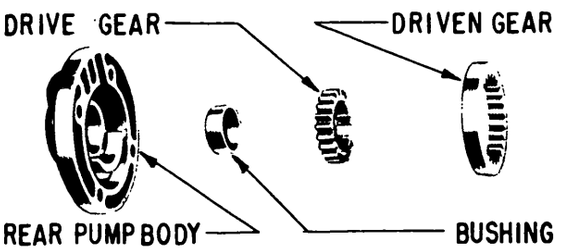


FRONT PUMP & REVERSE PISTON: Disassembly - Remove gasket and square oil seal ring. Remove reverse piston by using air pressure and applying air to reverse port in pump cover (stator support). Remove square oil seal ring from inner diameter of reverse piston, then remove five hex lock bolts holding pump cover to front oil pump body and remove oil pump body from cover. Remove both pump gears. *NOTE - Two lugs on drive gear are installed toward front of pump body and mate with slots in converter housing hub.*

Inspection: Wash all parts in solvent and blow out all oil passages *(CAUTION - Do not use rags to wipe parts).* Inspect all parts for nicks or scores. Inspect seals for hardness, wear, damage or evidence of oil leakage. If pump body oil seal is damaged, pry out and install new seal with Tool J-6584. Inspect splines on stator shaft for wear and check both ends of shaft inner diameter for wear. Inspect reverse piston for damage and inspect reverse drive, reaction and pressure plates for wear or heat. Replace if necessary. Inspect pump body bushing for galling or scoring. Check clearance between pump body bushing and converter pump hub. Maximum clearance should be .005". Inspect reverse piston spring for heat damage. With all parts clean and dry, install pump gears and check as follows: Clearance between outside diameter of driven gear and body should be .0025-.0055". Clearance between driven gear and crescent should be .003-.009". With scale and feeler gauge, check gear end clearance which should be .0005-.0015".

R assembly: Remove gears from pump body after checking and lubricate with automatic transmission fluid, then reinstall gears in pump body. *NOTE - Drive gear is installed in pump body with lugs toward body (lugs mate with slots in converter housing). If installed backward, pump will not operate.* Assemble pump cover (stator support) through drive gear and align attaching bolt holes. Install hex lock bolts but do not tighten. Install concentricity gauge J-6560 over front extension of pump cover to pump body, then tighten the hex lock bolts to 18-22 ft. lbs. and remove gauge. Install square seal ring in inner diameter of reverse piston (lubricate with transmission oil before installation), and install square seal ring to outer diameter of reverse piston. Position reverse piston to front pump cover and press into place with fingers. Install square seal ring to outer edge of pump cover, then place gasket on rear face of cover.

FRONT PUMP & REVERSE PISTON ASSEMBLY



SUN GEAR FREEWHEEL ASSEMBLY

REAR PUMP: Disassembly - Remove pump gears and wash parts with solvent. Blow out all oil passages and check parts for visible damage. Install gears and check all clearances which are the same as for the front pump (see above). *NOTE* - Use output shaft in place of converter to make check for clearance between output shaft and pump bushing.

Rear Pump Body Bushing - Use precision bushing, Part No. 3727490, which requires no reaming, for service replacement. Cut bushing with a chisel and remove from pump body. Press new bushing into pump body with Tool J-6582. Bushing should be flush with neck of pump body on the inside, and flush to .010" below front surface of pump body.

Reassembly: Lubricate all parts with automatic transmission fluid. Reverse the disassembly procedure.

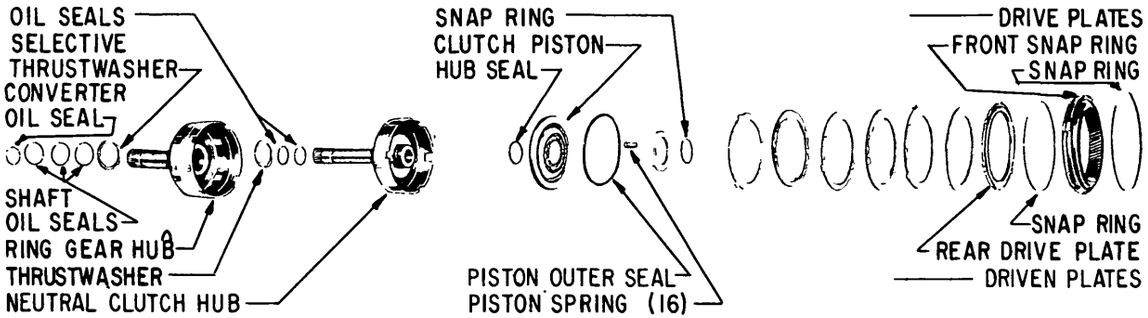
FRONT SUN GEAR FREE WHEEL ASSEMBLY: Disassembly - Remove needle thrust bearing assembly in opening in the rear of sun gear. Remove snap ring in outer cam from rear of assembly with a screwdriver. Remove forward clutch freewheel sprag assembly and outer bearing from sun gear (sun gear may have to be rotated clockwise to freewheel out of cam). Remove sprag assembly from outer cam. *NOTE - The sprag assembly*

REAR PUMP ASSEMBLY

should not be disassembled. An arrow stamped on outer cage of sprag assembly designates front of transmission. Remove sheet metal retainer from sun gear using pliers and bending retainer at the staking points. Remove ring gear freewheel sprag assembly and bearings.

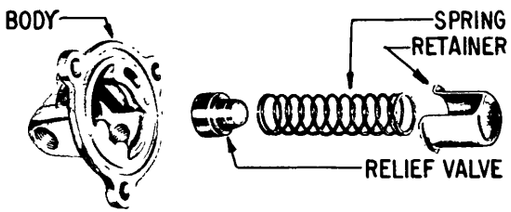
Inspection: Wash all parts in solvent and blow dry with air *(CAUTION - Do not use rags to wipe parts).* Inspect inner race (sprag bearing surface) of cam for excessive scoring or burning. Also check lugs on outer perimeter of cam for nicks or burrs. Check bushings in sun gear for looseness or bushing scoring. Replace if necessary. *(NOTE* - Bushings must be replaced in pairs with sun gear removed from freewheel unit). Inspect front sun gear teeth for nicks and burrs and for fit of sun gear into front planetary unit. Inspect internal and external races (sprag bearing surfaces) of sun gear for excessive

CONTINUED ON NEXT PAGE



CHEVROLET TURBOGLIDE (C nt.)

scoring or burning. Inspect sprag bearing for excessive wear. Check sprag assemblies and if wear is indicated, replace the assembly.

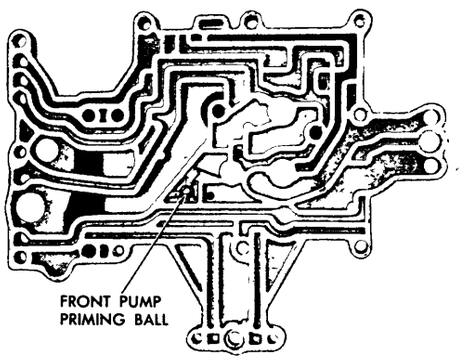


Front Sun Gear Bushing Replacement - Use precision bushings, Part No. 3727244, which require no reaming, for service replacement. *(CAUTION - Do not attempt replacement of these bushings with freewheel unit assembled).* Remove old bushings with Tool J-6581, using removal end of tool. *(CAUTION - Before installing bushings, note position of oil grooves in bushings. These grooves must point outward to maintain oil reservoir in sun gear).* Using Tool J-6581, mount sun gear in press and press bushings into place.

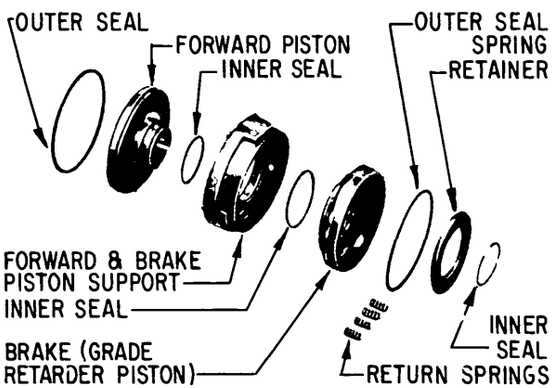
R assembly: Install front retainer, then large sprag front bearing (brass) into cam. Install sprag into cam *(NOTE - Stamped arrow on outer cage of sprag assembly indicates front of transmission),* compress unit into cam with fingers (do not force). Install large sprag rear bearing (brass) into cam, then set aside for further assembly. Install front bearing (brass) into rear of sun gear. Install sprag, then install rear bearing (brass) into sun gear. Index tang of new seal retainer into hole in rear of sun gear and clamp in vise, using a steel block and wood block, and stake retainer into place using a staking tool which must be sharp and give a "fingernail" impression *(CAUTION - Shield retainer must be held snug to rear of sun gear while staking operation is performed. Be very careful not to bend shield).* Index sun gear into forward clutch sprag, twisting clockwise to enable sprag cams to twist, allowing sun gear race to seat under sprags while twisting. Install rear bearing into cam. *NOTE - Sprags are assembled correctly if units will slip while holding outer cam stationary and turning sun gear clockwise as viewed from the front.*

NEUTRAL CLUTCH & FRONT RING GEAR: Disassembly - Remove converter turbine shaft oil seal ring from front of ring gear hub shaft. Remove three turbine shaft oil seal rings and lift converter turbine shaft ring gear thrust washer off shaft- *NOTE - This washer is selective fit for proper clearances within transmission.* Remove front planet ring gear retainer ring with a sharp instrument and remove ring gear from hub. Remove hub from turbine shaft and neutral clutch assembly. Remove two third turbine shaft seal oil rings from turbine shaft, then remove plate retaining snap ring and lift out rear drive plate, clutch drive plates, and driven plates. *NOTE - Plate retaining snap ring is staked in place. Remove staking by driving on snap ring with a punch and hammer.* To remove spring retainer snap ring, place neutral clutch assembly in an arbor press and compress springs with Tool J-5133 and J-7150, then remove snap ring and slowly release press. Lift off spring retainer and remove 16 springs. To remove neutral piston apply air to check ball (piston will blow out). Remove neutral piston outer seal and piston hub seal. *NOTE - Ball check in neutral clutch hub must be fr to move off seat .030" minimum and hole should be fr of chips and dirt. Ball check is not removabl .*

NEUTRAL CLUTCH & RING GEAR ASSEMBLY



THERMAL BYPASS VALVE



Front Ring Gear Hub Bushing Replacement - Front ring hub is not serviced separately. If bushing fails, replace complete front gear hub assembly.

Reassembly: *NOTE - Lubricate rubber seals with automatic transmission fluid before assembling.* Install neutral clutch piston hub seal ring to center raised portion of hub, then install neutral clutch piston outer seal on piston. Install neutral clutch piston into clutch hub (apply hand pressure evenly around piston to aid in piston installation). Arrange 16 piston springs on neutral clutch piston in a circle in piston spring groove, then place spring retainer on springs. Place assembly in an arbor press, then install snap ring in approximate position and compress springs with Tool J-5133 and J-7150. Make sure snap ring is properly seated, then remove neutral clutch from arbor press. Install externally tanged drive plates and internally splined driven plates alternately in neutral clutch hub starting with a drive plate. Install rear drive plate and secure all plates with snap ring. Stake retainer plate against snap ring in three places. Install ring gear hub bushing, then two third turbine shaft seal rings. Insert neutral clutch hub into front ring gear hub being careful not to break seal rings on third turbine shaft. Key front ring gear to ring gear hub (larger tapered portion of ring gear must be up or snap ring cannot be installed). Install front ring gear retainer ring in hub, making sure it seats fully in bottom of ring groove. *NOTE - Oil seal rings and selective washers are not installed at this time as it would be necessary to remove them for selecting proper thrust washer during assembly.*

FORWARD PISTON, BRAKE PISTON & SUPPORT: Disassembly - Position the assembly on press bed with retaining ring upward, then use Tools J-7782 & J-5133

FRONT PRIMING BALL LOCATION

FORWARD & BRAKE PISTON

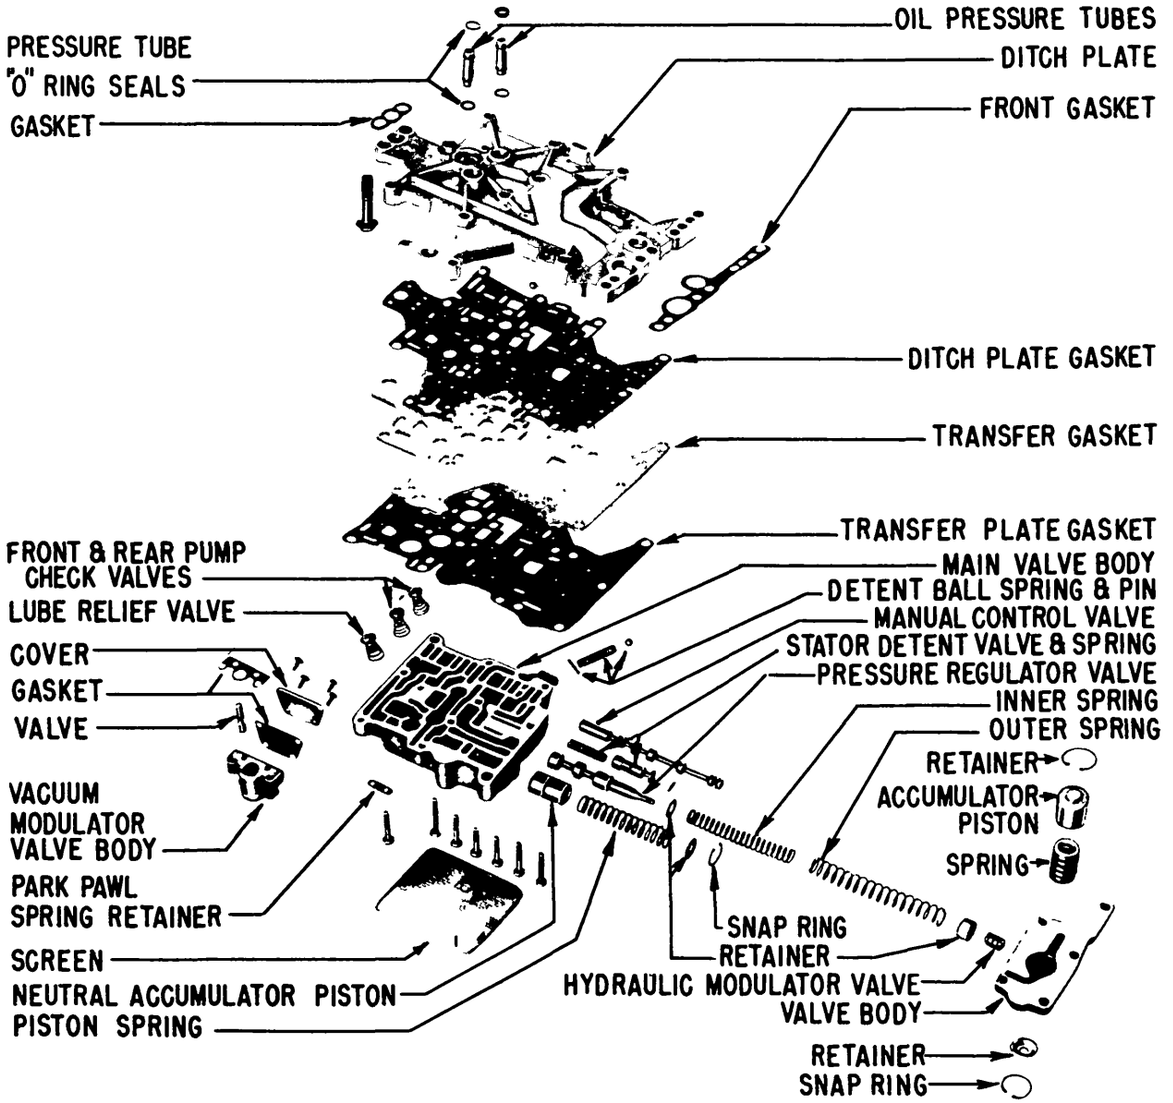
to compress spring seat and remove retaining ring, spring seat, and twenty coil springs. Remove forward piston and brake piston from support by blowing air under pressure into forward and brake piston pressure ports. Remove the two seals from forward piston outer diameter and seals from outer and inner diameters of brake piston.

Inspection: Wash all parts in solvent and blow dry with air. Inspect all parts for indications of heat damage. Inspect all surfaces contacting seal rings for scoring

CONTINUED ON NEXT PAGE

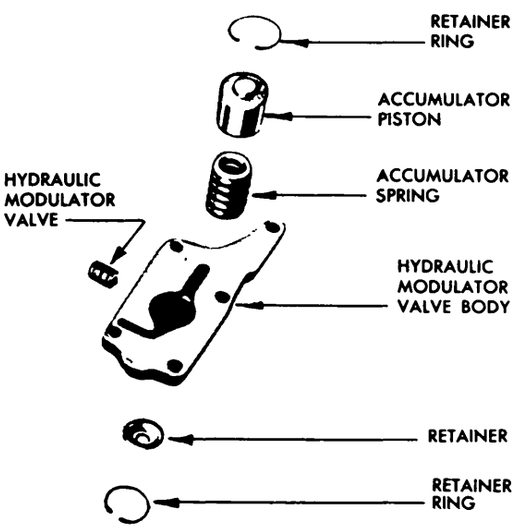
CHEVROLET TURBOGLIDE (C nt.)

or burning, then check fits of forward and brake piston into support. Inspect inside diameter of forward piston which mates with ring gear for nicks or burrs.



R ass mbly: Assemble new seals to outside diameter of forward piston and to outside and inside diameters of brake piston. Lubricate seals and carefully install forward piston in support using extreme care to avoid damage to seals as they enter support. Fully seat forward piston in support. Position Tool J-7781 on support hub to protect seal on inside diameter of brake piston, then carefully guide brake piston into support over seal protector using care not to damage large seal on brake piston as it enters support at slightly chamfered edge. Set unit in a press, forward piston end down, and assemble 20 springs to brake piston. Place spring seat over springs, then use Tools J-7782 and J-5133 in arbor press and compress seat and springs and install retainer.

TRANSMISSION CASE REAR BUSHING REPLACEMENT: *NOTE - This bushing is a precision type and does not require reaming or finishing after installation.* Place transmission case on bench with rear of case upward, then use remover end of Tool J-7562 and press or tap bushing from case (from rear of case to front). To install the bushing, use opposite end of tool and press ortap bushing from outside of case toward the front until tool stop is reached. *NOTE - Open nds of bushing oil groove must be toward rear of case.*



CONTROL VALVE BODY: Disassembly - *NOTE - Note locations of various lengths of bolts as they are removed.* Remove manual valve, then remove valve body screen and vacuum modulator assembly. Remove two attaching bolts securing hydraulic modulator valve body assembly to ditch plate (while holding valve body against spring pressure), then remove valve body assembly, inner and outer pressure regulator spring, and spring retainer. Remove parking pawl spring retainer and the remaining screw on oil screen side of assembly which holds main valve body to ditch plate. Invert valve body assembly and remove nine bolts holding ditch plate to main valve body assembly. Separate the ditch plate from transfer plate and main valve body. Remove gasket between ditch plate and transfer plate, then remove front pump priming ball from cavity in ditch plate. Remove gasket between transfer plate and main valve body. Remove front and rear pump check valves and lube relief valve with their springs. *NOTE - Front and rear pump check valve springs are interchangeable. Lube relief valve spring is heavier and is not interchangeable. The three valves are interchangeable.* Check stator detent valve for freedom of operation. If valve requires removal, then remove roller pin, valve and spring. Remove neutral accumulator piston spring seat snapring with Tool J-5403, then remove seat, spring and piston. If required, remove detent ball pin, spring, and detent ball. Remove pressure regulator valve and spring seat washer. If required, remove seven socket head pipe plugs from valve body.

Vacuum Modulator Valve - Remove cover screws and lift off cover and gasket, then remove valve and base plate. To reassemble, insert modulator valve into

CONTINUED ON NEXT PAGE

VALVE BODY ASSEMBLY

HYDRAULIC MODULATOR

CHEVROLET TURBOGLIDE (C nt.)

valve body, then install cover using a new gasket. Tighten screws evenly, then install a new base gasket.

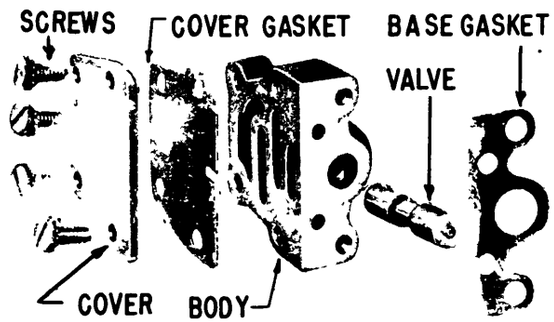
Hydraulic Modulator Valve - Remove valve from valve body, then compress piston and spring and check for free movement. If disassembly is required, depress accumulator piston with a narrow hammer handle and remove retainer ring with Tool J-5403. Slowly release pressure on accumulator piston, then remove piston and spring. Remove retainer ring and retainer from opposite side of valve body. To reassemble, install one retainer ring in bottom of valve body with Tool J-5403, then install retainer. Install accumulator piston spring and piston, then depress accumulator piston into bore with a hammer handle and install retainer ring, making sure ring is fully seated before releasing pressure on accumulator valve. Install hydraulic modulator valve.

R assembly: Install the seven pipe plugs in valve body, then install detent ball, spring, and roll pin. Install neutral accumulator piston, spring, and seat into main valve body, then hold seat over spring and compress and install snap ring into groove. If removed, install stator detent valve spring in main body, then install detent valve with hollow end positioned over spring. Depress valve and tap in roll pin to engage groove in end of valve. *NOTE --Do not install pin too deeply as end of pin should not touch bottom of groove.* Check valve for freedom of movement after installation of pin. Install spring seat washer to pressure regulator valve and install valve and seat in valve body. Install front and rear pump check valves and lube relief valve. *NOTE - Lube relief valve has heavier spring. Front and rear pump check valve springs are interchangeable. All three valves are interchangeable.* Install front pump priming ball in ditch plate (see illustration). Install large hollow bolt through rear hole in ditch plate to aid in alignment of gaskets and components. Install gasket on ditch plate, then install transfer plate to gasket. Install gasket on main body and install transfer plate and ditch plate to valve body by grasping assembly and indexing lube relief valve and front and rear pump check valves of main body with holes in transfer plate. *CAUTION - Be sure gaskets are not torn or damaged during installation.* Hold ditch plate down and install nine shorter bolts finger tight to ditch plate side of assembly. *NOTE - Excluding the two smaller vacuum modulator attaching bolts, the eleven shorter bolts are installed to ditch plate side of the assembly and are all the same size. Nine of these bolts attach ditch plate and transfer plate to main valve body and two attach hydraulic modulator body to ditch plate. The two longer valve body to ditch plate bolts are installed to main valve body side of the assembly.* Install inner and outer pressure regulator valve springs in pressure regulator bore of valve body and install spring retainer on end of springs. Position hydraulic modulator body assembly so that pressure regulator springs enter hydraulic modulator valve bore in body, then compress springs and install two remaining shorter bolts finger tight to secure hydraulic modulator unit to ditch plate. Tighten all bolts on ditch plate side to 9-12 ft. lbs. working outward from the center. Invert the assembly and install parking pawl spring retainer and longer bolt through main valve body side and tighten to 9-12 ft. lbs. Install diagonally opposite longer bolt through main valve body and tighten to 9-12 ft. lbs. Use a new gasket and position vacuum modulator assembly on ditch and transfer plates, then install attaching screws and tighten securely. Install valve body screen and slotted head bolt, then install manual valve.

REAR EXTENSION HOUSING REAR OIL SEAL REPLACEMENT: Place extension housing on a wooden surface and remove oil seal using a cape chisel or punch *(CAUTION - Be careful not to damage aluminum case).* Using Installing Tool J-5154, install seal in extension housing.

► *EXTENSION HOUSING BUSHING NOTE: This bushing is precision bored in position and is not replaceable.*

of neutral clutch on bench and install freewheel sprag assembly over rear extension of planetary. Twist sprag assembly to mate sun gear to planetary gears. Install needle thrust bearing over extension of front planetary gear extending through freewheel unit.



TRANSMISSION REASSEMBLY

REASSEMBLY: 1) Install vacuum modulator gasket and modulator assembly, then install square seal ring and bypass valve assembly. Tighten bolts to 7-9 ft. lbs. Install parking lock pawl and pawl shaft with new "O" ring seal in case.

2) Install parking lock bracket to case with two screws and lockwashers and tighten to 7-9 ft. lbs. Assemble parking lock actuator assembly, parking lock and range selector inner lever and secure with "C" retainer. Install parking lock and range selector outer lever and shaft through case, then assemble inner lever to outer lever shaft and tighten screw and nut.

3) Install throttle valve control outer lever with washer and new "O" ring seal installed to shaft through center of parking lock and range selector lever shaft. *NOTE - Washer must be positioned so inner lip will enter seal.* Assemble inner throttle valve lever to outer lever shaft and secure with "C" retainer.

4) Lubricate and install needle thrust bearing race and bearing on front hub of rear planet carrier. Dip caged needle thrust bearing in transmission oil, assemble over output shaft of rear planet carrier and stick to carrier with petroleum jelly. Lubricate all gears and friction surfaces before installing.

VACUUM MODULATOR VALVE ASSEMBLY

5) Lubricate and assemble rear ring gear unit to rear planet carrier assembly with bearings installed. Hold up parking lock pawl and insert entire unit into case (support output shaft during installation). Install brake (grade retarder) clutch pack in following sequence: **Thin** steel reaction plate, faced brake plate, **thick** steel reaction plate, faced brake plate, **thick** steel reaction plate, faced brake plate, and **thin** steel reaction plate. *NOTE - The three steel reaction plates are internally tanged and engage in grooves in rear ring g ar hub. The four reaction plates are externally tang d for engagement into grooves in transmission case. Align all internal notched tangs on faced brake plates.*

6) Install forward and brake piston and support assembly. Seat assembly by tapping with brass drift. *NOTE - Pressure tube ports point toward valv body or bottom of transmission and align with holes in cas when seated.* Install forward and brake piston support retainer ring in case. *NOTE - Do not position ring gap at grooves in case.* Lubricate and install needle thrust bearing into rear cavity of front sun gear freewheel assembly (overrun sprag clutch unit) and install assembly in case. *NOTE - Races not used with this bearing.*

7) Lubricate and install forward clutch pack in the following sequence: Steel reaction plate, then a faced brake plate, repeating this sequence to complete the pack of four steel reaction plates and three faced brake plates. Finally install the thick steel pressure plate. *NOTE - Notched tangs on reaction plates must be in alignment.* Install forward clutch retainer ring in case. *NOTE - Do not position ring gap at case groov s.*

8) Assemble new "O" rings in top groove of each oil pressure tube and in the brake (grade retarder) and forward clutch orifices, making sure they are fully seated, then install tapered ends of pressure tubes into "O" rings in orifices and check forward and brake pistons for leakage.

9) Apply a small amount of petroleum jelly and locate tanged thrust washer on front end of front planet carrier. Also lubricate and install needle bearing race and and bearing over front planet carrier extension. Install thrust ring in groove on front planet extension. Lubricate and install front planet carrier in case.

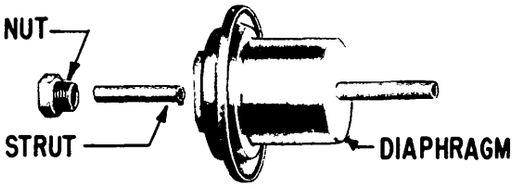
10) Install neutral clutch and front ring gear assembly over front planet carrier, then hold front ring gear shaft while turning the outer shaft to engage neutral clutch plates with front planet carrier. Lubricate and install reverse clutch reaction insert and rear pressure plate in case. Alternately install faced plates and steel reaction plates in insert, then complete assembly by installing the original selective reverse front pressure plate. Install reverse piston spring with coned side of spring facing front of transmissions.

11) Install new square seal ring on outer lip of stator support. Align tangs of oil pump drive gear to top and bottom of pump housing. *NOTE - Transmission must be in a vertical position with front end facing upward to avoid damage to oil seal rings on second turbine shaft during front pump and conv rter installation. Align oil seal ring gaps for as of installation.* Install two guide studs J-3387-10 in case to guide front pump to avoid damaging oil seal rings on front ring gear hub shaft.

CONTINUED ON NEXT PAGE

CHEVROLET TURBOGLIDE (C nt.)

12) Install front pump gasket on case, then lubricate four oil seal rings on second turbine shaft with petroleum jelly and center rings on shaft. Index pump on guide studs and carefully guide pump over oil seal rings. If necessary, tap pump housing to seat it in case. Check second turbine shaft for free rotation. If shaft binds, remove assembly and check for broken seal rings. Install four of the front pump mounting bolts and tighten to 15-18 ft. lbs. and recheck second turbine.



13) Check for correct selective reverse front pressure plate running clearance as follows: Position transmission so output shaft is horizontal, then using feeler gauges, measure clearance between selective reverse pressure plate and the adjacent faced plate. *CAUTION - B car ful to measure only the clearance, making sure that clutch pack plat s are not being compressed by ins rtion of the feeler gaug s.* Clearance should be .025-.050". If clearance not within limits, disassemble reverse clutch pack and install a thicker or thinner selective reverse plate as required. Three sizes of reverse pressure plates are available as follows:

R v rs Pr ssure Plates

Thickn ss ℄	Id ntification ②	Part No.
.5971"	1	3759803
.5814"	2	3759804
.5657"	3	3759805

℄ - Plus or minus .003".
② - Number of depressions in plate.

14) To check for correct thickness of washer on front ring gear hub, position transmission so output shaft is down, then mount dial indicator so plunger of indicator is resting on end of neutral clutch hub. Push upward on output shaft and note total indicator movement. Clearance should be .008-.028". If clearance is within limits, remove guide studs, then coat all front pump bolts with non-hardening sealer and install. Tighten bolts to 15-18 ft. lbs. If clearance is not within limits, remove front pump and reverse piston assembly and change the selective washer. Washers are available in thicknesses of .068", .085", .103". Recheck second turbine shaft for free movement after reassembly.

VACUUM DIAPHRAGM

15) Install converter assembly engaging the two slots in converter pump hub with lugs in front pump drive gear. *NOTE - Lift converter up and down while turning slightly to engage pump lugs. The converter will drop approximately ½" further when engagement with front pump lugs is attained.* Measure from front of case to front of converter. If measurement is a minimum of ¾", all parts are properly engaged. Install converter Holding Tool J-5384, then turn transmission parallel to floor, bottom side upward. Air check stator piston for air leakage.

16) Turn output shaft to locate drive pin hole at top of output shaft, then install wear plate and rear pump drive pin. Position rear pump on output shaft, indexing drive gear to drive pin, then install two lower oil pump bolts which are not used to secure oil deflector. Tighten bolts snugly. Install speedometer drive gear with Tools J-5814 and J-5814-15. *NOTE - Front face of driv gear should be ¼" from rear pump.* Install oil deflector and remaining two rear oil pump bolts and tighten bolts snugly. Install seal ring around pump body and against rear face of case. *CAUTION - Converter assembly must be in transmission before rear oil pump bolts are tightened.* Install transmission extension and bolts and tighten securely.

17) Using a universal joint slip yoke, check for free movement of output shaft. If there is binding, center rear oil pump by tapping on extension with soft hammer until shaft turns freely. When output shaft turns freely, carefully remove extension to avoid shifting oil pump. Tighten rear oil pump bolts to 7-9 ft. lbs. Install extension and tighten the five mounting bolts to 23-26 ft. lbs. Install slip yoke and recheck for free rotation of output shaft. If removed, install speedometer driven gear in extension, position retainer and tighten capscrew to 3½-5 ft. lbs.

18) Install vacuum modulator plunger, then install new new gaskets on front and rear of valve body or case. Position valve body on case, making sure that selector inner lever engages with manual valve and detent ball and that pressure tubes and vacuum modulator plunger enter valve body. Install and tighten front bolts to 8-10 ft. lbs., and rear hollow bolt to 18-21 ft. lbs. Install parking pawl spring to pawl retainer on rear of valve body. Install oil pan gasket and oil pan. Tighten capscrews to 3-4 ft. lbs.

CORVAIR TRANSAXLE

C rvair (1960)

DESCRIPTION: The Transaxle consists of either an integral differential (rear axle) assembly and synchro-mesh transmission; or a differential (rear axle) assembly and a Powerglide transmission as follows:

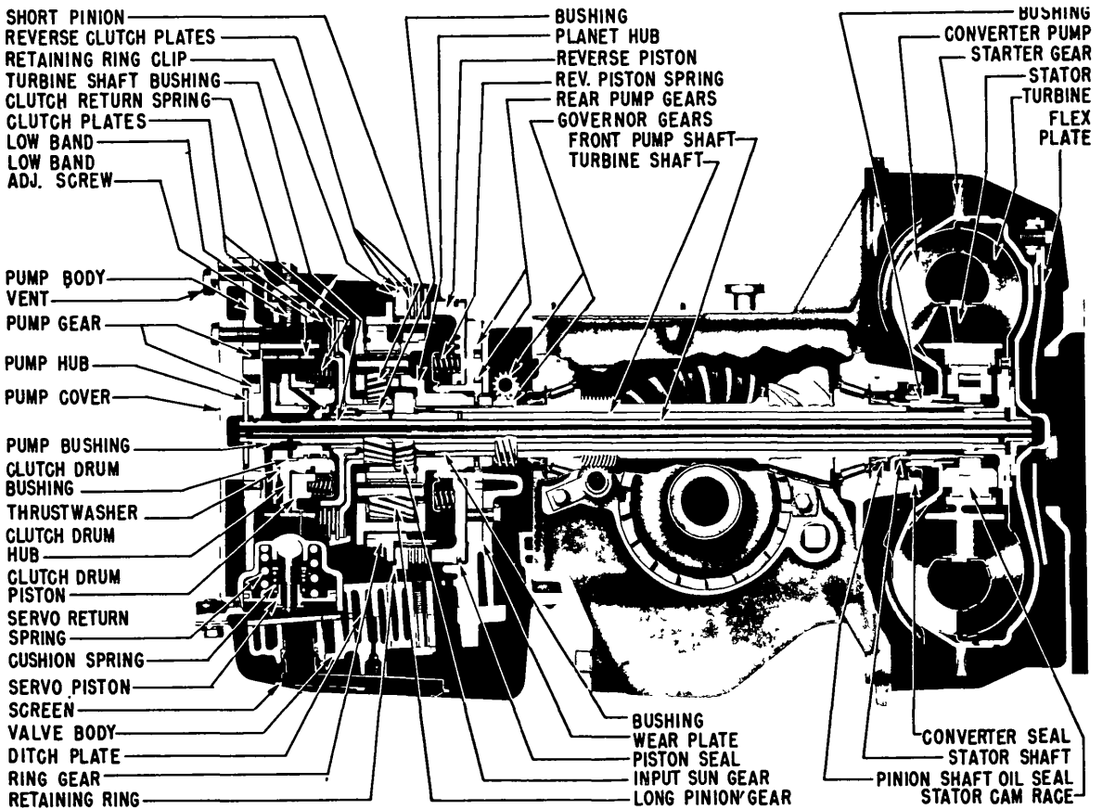
Differential (Rear Axle) Assembly: Straddle mounted hypoid gear type of new design with transmission input & output shafts running axially through differential pinion shaft. This unit which is contained in a separate carrier housing is located between transmission (either Synchro-mesh or Powerglide) and the engine assembly.

Synchro-mesh Transmission: Three-speed synchro-mesh type integral with rear axle differential carrier. Because of attachment to differential carrier, a hollow mainshaft is used to permit passage of the clutch shaft to front of transmission for engagement of clutch gear with countergear. *NOTE - Except for counter-g ar and clutch gear, all transmission gears are interchangeable with the conventional Chevrolet 3-Speed synchro-mesh transmission.*

P werglide Transmission: Three element torque converter and a hydraulically operated two-speed type automatic shift transmission integral with rear axle differential carrier. Converter torque from the welded type torque converter assembly located between differential carrier and engine is transmitted to transmission through two hollow shafts running through the hollow differential pinion shaft. One shaft runs from converter cover hub to transmission front pump and the other from the turbine to transmission input sun gear.

LUBRICATION

Check fluid level in all units every 1000 miles. Drain and refill every 10,000 miles (Rear Axle & Synchro-mesh Trans.). *NOTE - Draining and refilling of Powerglide Trans. not recommended except at time of overhaul.*



Recommended Oil (Rear Axle & Synchro-mesh Trans.) - SAE 80 "Multi-Purpose" gear lubricant. *CAUTION - Do not use "Mineral Oil" gear lubricants or any "active surphur soap" lubricants.* Differential carrier & transmission are connected by internal passages.

Powerglide Trans. - Automatic Transmission Fluid Type "A" (Suffix "A"). *NOTE - Automatic transmission is sealed off from differential carrier.*

Checking Fluid Level: Rear Axle & Synchro-mesh Trans. - With unit at normal operating temperature, check fluid in differential carrier first (plug is adjacent to rear axle universal joint on left side of transmission case). If level is low in differential carrier, also check level in transmission. *NOTE - With unit at operating temperature, fluid should be level with bottom of filler plug hole. If unit is cold, fluid should be ½" below filler plug hole.*

Powerglide Transmission - With transmission at normal operating temperature and transmission selector lever in "N" position, engine idling, check fluid level on dipstick in filler tube at right side of engine near firewall. Add fluid as necessary to bring level to "Full" mark on dipstick, using recommended fluid.

Draining & R filling: R ar Axl - Drain carrier housing and replace drain plug. Refill housing with 3.1 pints of recommended fluid.

CORVAIR POWERGLIDE TRANSMISSION SECTIONAL VIEW

Rear Axle & Synchro-mesh Trans. - Remove drain plug in transmission housing and in differential carrier housing. *NOTE - Transmission drain plug is on left side adjacent to idler arm on side of transmission case.* Refill by adding lubricant to both units (5 pints total). Check level at both units after refilling.

Powerglide Trans. - *NOTE - Not required except at time of transmission overhaul.* Drain oil by loosening filler tube attaching nut in oil pan. Tighten filler tube nut and add 4 pints of recommended fluid using filler tube and funnel J-4264. Start engine and allow to idle 3-5 minutes in "N", then add sufficient fluid to bring level to "Full" mark. Capacity is 6 pints (approximately) for normal refill. 13 pints (approximately) with transmission and torque converter dry.

ADJUSTMENT

Transmission Shift Linkage (Synchro-mesh Trans.): Loosen universal joint clamp nut at transmission end of shift shaft, then move manual shift shaft on transmission so transmission is in first speed position. Hold selector lever and tighten universal joint clamp bolt. Check shift in all positions.

Transmissi n Thr ttl Linkag (P w rglid Trans.): *Se "Accel rator Control Linkag Adjustm nt" under CARBURETOR on car model page.*

Manual Linkag (P w rglid Trans.): Drain transmission oil and remove oil pan. Place transmission selector lever in "D" (Drive) range, then insert Tool J-8365 into manual valve bore (end opposite linkage) with tab of gauge upward so it engages forward port of valve body. With tool in place, push forward on manual valve levers. If valve is properly adjusted, tool will be held in place horizontally without being supported. If adjustment is necessary, loosen lockscrew in manual valve linkage (inside transmission) and push manual valve levers forward so Tool J-8365 is held in a horizontal position. Recheck adjustment. Install oil pan and fill transmission with fluid.

Neutral Starter Switch Adjustm nt (P w rglid Trans.): Loosen two switch mounting screws and place transmission selector lever in "N" (Neutral) position. Turn ignition switch to "Start" position, then move Neutral Switch fore and aft until engine cranking begins. Secure switch in that position. Recheck to make sure engine will not start with transmission selector lever in any position other than "N" (Neutral).

Low Band: Remove parcel shelf behind rear seat and remove plug covering access hole in floor. Loosen locknut and tighten the square head adjusting screw to 40±5 inch pounds, **then back ff adjusting scr w 4 full turns xactly.** Hold adjusting screw stationary and tighten locknut.

CONTINUED ON NEXT PAGE

CORVAIR TRANSAXLE (C nt.)

►*ADJUSTING TOOL NOTE:* A wrench for turning the adjusting screw locknut can be made by welding two ¾" tubular steel spark plug wrenches together (end-to-end) so wrench can be installed over adjusting screw locknut. A square socket wrench can be inserted through this tool to engage adjusting screw.

TROUBLE SHOOTING

NO DRIVE IN ANY SELECTOR LEVER POSITION (CANNOT LOAD ENGINE): Low oil level. Clogged oil suction pipe screen. Broken or disconnected manual cable. Defective pressure regulator valve. Defective line pressure limit valve. Defective front pump. Rear pump check valve and rear pump priming ball not seating (both must occur for possible malfunction). Front pump shaft disengaged at either converter or pump gear. Front pump priming ball not seating.

ENGINE SPEED FLARES ON STANDSTILL STARTS BUT ACCELERATION LAGS: Low band only partially applied caused by one or more of the following conditions: Low oil pressure. Clogged pickup pipe screen. Improper band adjustment. Servo piston apply passage blocked. Servo piston ring broken or leaking. Band facing worn. Low band apply linkage disengaged or broken. Converter stator not holding.

ENGINE SPEED FLARES ON UPSHIFT: Low oil level. Clogged oil suction screen or pipe. High clutch partially applied (blocked feed orifice). Clutch plates worn. Clutch seals leaking. Clutch piston hung up. Clutch drum relief ball not seating. Vacuum modulator hose collapsed.

TRANSMISSION WILL NOT UPSHIFT: Low band not releasing due to one of the following conditions: Stuck low-drive valve. Defective governor. No rear pump output (stuck priming ball, drive pins not engaged, or defective pump). Throttle valve stuck or improperly adjusted. Improperly adjusted manual valve lever.

HARSH UPSHIFT: Incorrect carburetor-to-transmission throttle valve rod adjustment. Improper low band adjustment. Vacuum modulator hose broken or disconnected. Vacuum modulator diaphragm leaks. Vacuum modulator valve stuck. Hydraulic modulator valve stuck.

CLOSED THROTTLE HARSH DOWNSHIFT: Improper low band adjustment. Vacuum modulator hose disconnected or broken. Vacuum modulator diaphragm ruptured. Vacuum modulator valve stuck. Engine idle speed too high. Sticking pressure regulator or hydraulic modulator valves in valve body.

CAR CREEPS EXCESSIVELY IN DRIVE: Idle speed too high.

CAR CREEPS IN NEUTRAL: Incorrect manual valve lever adjustment. High clutch or low band not released.

NO DRIVE IN REVERSE: M .ual valve lever adjustment not correct. Cable linkage adjustment not correct. Reverse clutch piston stuck. Reverse clutch plates worn out. Reverse clutch leaking excessively. Blocked reverse clutch apply orifice.

IMPROPER SHIFT POINTS (see "Shift Speed" table b low): Incorrect accelerator control linkage adjustment. Throttle valve incorrectly adjusted. Governor defective. Rear pump priming ball stuck.

OIL FORCED OUT OF FILLER TUBE: Oil level too high. Oil pickup pipe split or not sealed causing air entrainment.

UNABLE TO PUSH START: Rear pump drive gear not engaged with drive pins on planet carrier hub. Rear pump defective. Rear pump priming ball not seating.

TESTING

►*TESTING NOTE: Transmission must b at normal operating temp rature, fluid level at "F" mark on dipstick, and manual and throttle linkage adjustments must be correct.*

:OAD TEST: Road test car to determine transmission shift points as indicated in table below.

Transmission Shift Speeds

	MPH
UPSHIFTS:	
Minimum Throttle	10–12½
Full Throttle	41–47
Part Throttle (Detent Touch)	34–41
DOWNSHIFTS:	MPH
Closed Throttle	8–12
Full Throttle	38–44
Part Throttle (Detent Touch)	23–30
Manual Low (Inhibited)	41–46

PRESSURE TESTS: *NOTE – Pressure tests can be made by raising rear wheels 3–5" off floor on jack stands.*

Front Pump: Remove plug located at "6 o'clock" position in front pump cover (accessible through engine front mount) and connect pressure gauge. With engine at idle speed (approx. 16" of vacuum), pressures should be as follows with selector lever in the indicated range: 81–98 lbs. (Reverse); 47–57 lbs. (Neutral & Drive); 71–82 lbs. (Low). Disconnect vacuum hose at balance tube, then with engine at idle speed, check pressure which should be: 140–157 lbs. (Reverse); 71–82 lbs. (Neutral, Drive & Low). If there is no pressure in front pump, check for stuck pressure regulator, broken or disengaged front pump shaft, or missing plug from front end of front pump shaft. Moderately low front pump pressures in all ranges indicate a restricted front pump inlet. Failure of pressure to raise when vacuum hose disconnected (or high pressures with vacuum hose connected) indicates a stuck vacuum modulator valve, defective vacuum modulator, or a collapsed hose.

Rear Pump: With gauge connected as for "Front Pump" (rear wheels raised), place selector lever in "D" (Drive) and accelerate engine. Front pump pressure should drop to approximately 0–5 lbs. at 20 MPH. If pressure does not drop, rear pump is disengaged or clogged or rear pump check ball is not seating.

Throttle Valve: Remove plug located at "8 o'clock" position in front pump cover (accessible through engine front mount) and connect pressure gauge. Disconnect throttle valve rod at carburetor and vacuum hose at balance tube, then with engine at idle speed, depress accelerator to wide open position. *NOTE – By disconnecting throttle valve rod at carburetor, engine remains at idle speed throughout test.* Pressures should be as follows with selector lever in the indicated range: 0 lbs. (Reverse & Neutral); 52–54 lbs. (Drive); 66–77 lbs. (Low). If pressures not as specified, they can be corrected by adjusting the position of the jam nut located on end of detent valve assembly (part of throttle valve assembly inside transmission case). Insert an Allen wrench in end of adjusting screw and hold screw from turning, then turn jam nut as necessary. To raise pressure, back off jam nut (one full turn is equal to 3 psi). Tightening the nut lowers pressure.

REMOVAL & INSTALLATION

POWER TRAIN (ENGINE, TRANSMISSION & REAR AXLE): This complete assembly must be removed as a unit. See *"Engine" in Corvair Special Data.*

SYNCHRO-MESH TRANSMISSION: Rem val - With "Power Train" removed from car, support Transaxle assembly with a chain fall or suitable lift and sling, then drain transmission and differential carrier. Remove starter and the two screws securing clutch pull rod dust seal assembly, then remove pin attaching pull rod to clutch fork. Separate Transaxle from engine by removing attaching bolts securing differential carrier to clutch housing. Pull Transaxle away horizontally to prevent damage to clutch fork. Remove clutch shaft (transmission input shaft). Remove clutch fork and clutch release bearing from differential carrier. *NOTE - Fork is attached to carrier by a ball and socket and spring retainer.* Separate three-speed transmission from differential carrier by removing the four attaching bolts and disengaging transmission output shaft from splines in differential carrier.

Installation: Use a new gasket (hold in place with petrolatum), then couple transmission to differential carrier, being sure to engage splines of transmission mainshaft to internal splines of pinion in differential carrier. Secure transmission to carrier with four bolts (install two bolts on right side from transmission end and the two on left side from carrier end). Tighten bolts to 24-32 ft. lbs. Install clutch release bearing and clutch fork on differential carrier. *NOTE - Clutch release bearing slips over shaft and the fork has a spring retainer and socket which attaches to ball stud on carrier.* Install clutch shaft in Transaxle, then check distance from end of clutch release bearing shaft to end of clutch shaft. If fully engaged, the dimension should be 2 9/16"±1/32". Support Transaxle with a chain fall or other suitable lift and sling, then align attaching bolt holes in carrier and clutch housing. Pilot clutch shaft splines into clutch, then install attaching bolts and tighten securely. Connect clutch pushrod to clutch fork with pin, then position and secure clutch pushrod dust seal assembly. Install starter and fill transmission and differential carrier.

POWERGLIDE TRANSMISSION: Removal - With "Power Train" removed from car, drain transmission, then disconnect hose connecting modulator tube to carburetor balance tube. Remove engine front shield and remove starter. Disconnect converter from engine flex plate by removing the three attaching bolts through the access hole (at 12 o'clock position) in converter housing. Support Transaxle with a chain fall or suitable lift and sling, then remove attaching bolts and lockwashers securing differential carrier to converter housing. Pull Transaxle away from engine and remove converter assembly. Pull turbine shaft out of Transaxle assembly. Place Transaxle on a flat surface and remove screws securing governor assembly and remove governor. Remove three bolts securing transmission to carrier, then carefully pull transmission straight away from carrier to prevent pump shaft from damaging bushings in transmission and pinion shaft. Remove gasket from carrier, then remove governor gear and selective spacers from pinion shaft of carrier.

Installation: *CAUTION - Before connecting Powerglid transmission and differential carrier, determine thickness of thrust washers required at front face of governor gear. See "Rear Selective Thrust Washer" below.* After determining proper size thrust washer, install a new gasket to either carrier or rear face of transmission (hold in place with petrolatum). Align carrier and transmission on a flat surface and carefully guide the pump shaft through differential carrier so as not to damage

CONTINUED ON NEXT PAGE

CORVAIR TRANSAXLE (Cont.)

bushing in pinion, then engage splines of pinion shaft with planet carrier internal splines in transmission Install governor, then secure the transmission-to-carrier with four bolts Drive the two bolts from carrier side first (to minimize chance of cocking mating surfaces), then tighten bolts to 24-32 ft lbs Install turbine shaft, being careful not to damage its bushings as it is inserted over pump shaft splines *NOTE - Be sure to engage the two sets of splines (forward splines engage clutch drum and the rear set engage into sun gear in planet gearset)* DO NOT tip rear of Transaxle downward after installation unless converter holding plates are used Position Transaxle adjacent to engine on a chain fall or similar lift, then remove converter holding plates if installed Align converter with flex plate, then pilot converter hub onto crankshaft Align mounting holes in differential carrier and converter housing, then secure top left bolt (11 o'clock position) Install flex plate to converter bolt accessible at the "1 o'clock" position to prevent accidental turning of converter or flex plate and loss of attaching hole alignment Drive remaining converter housing-to-differential carrier mounting bolts, then install starter Drive the two remaining converter-to-flex plate bolts through the access hole in converter housing Install engine front shield, then reinsert filler tube through front shield and connect it to oil pan Connect vacuum modulator to carburetor balance tube with a short length of hose Refill transmission *(See "Draining & Refilling" above)*

Rear Selective Thrust Washer: *CAUTION - Any time repairs are made that require the separation of Powerglide transmission and differential carrier, the proper thickness of thrust washer to be used at front face of* governor gear *must be determined as follows* Install dial indicator on Support J-8364 and install a 3" indicator extension Without gasket, place support on rear pump cavity surface of transmission case (transmission front end down) so that dial indicator tip rests on planet carrier hub Adjust indicator as required to permit maximum indicator travel, then set dial to zero *NOTE - Transmission must face downward when indicator is zeroed* Slowly lift indicator and support off rear pump cavity and note its range of needle deflection from zero position *NOTE - If indicator is properly positioned on support, indicator should not deflect more than .050" (one-half turn) when removed, otherwise raise or lower dial indicator on support post as required and again "zero" gauge* Place support and dial indicator on governor gear on differential carrier pinion shaft (support J-8364 will fit over pinion shaft), then slowly lower support (indicator tip of dial indicator against machined face of differential carrier housing) so that revolutions of dial indicator can be counted *NOTE - Measurement starts once the indicator needle reaches "zero"* Fully depress support on governor gear and note indicator reading, then refer to following table for thickness of spacers to be installed on governor gear

►*NOTE After selected spacers are installed on governor gear, recheck measurement If spacer stack is correct, indicator reading will now be between .011-.038" If not, add or remove spacers until reading is within this range*

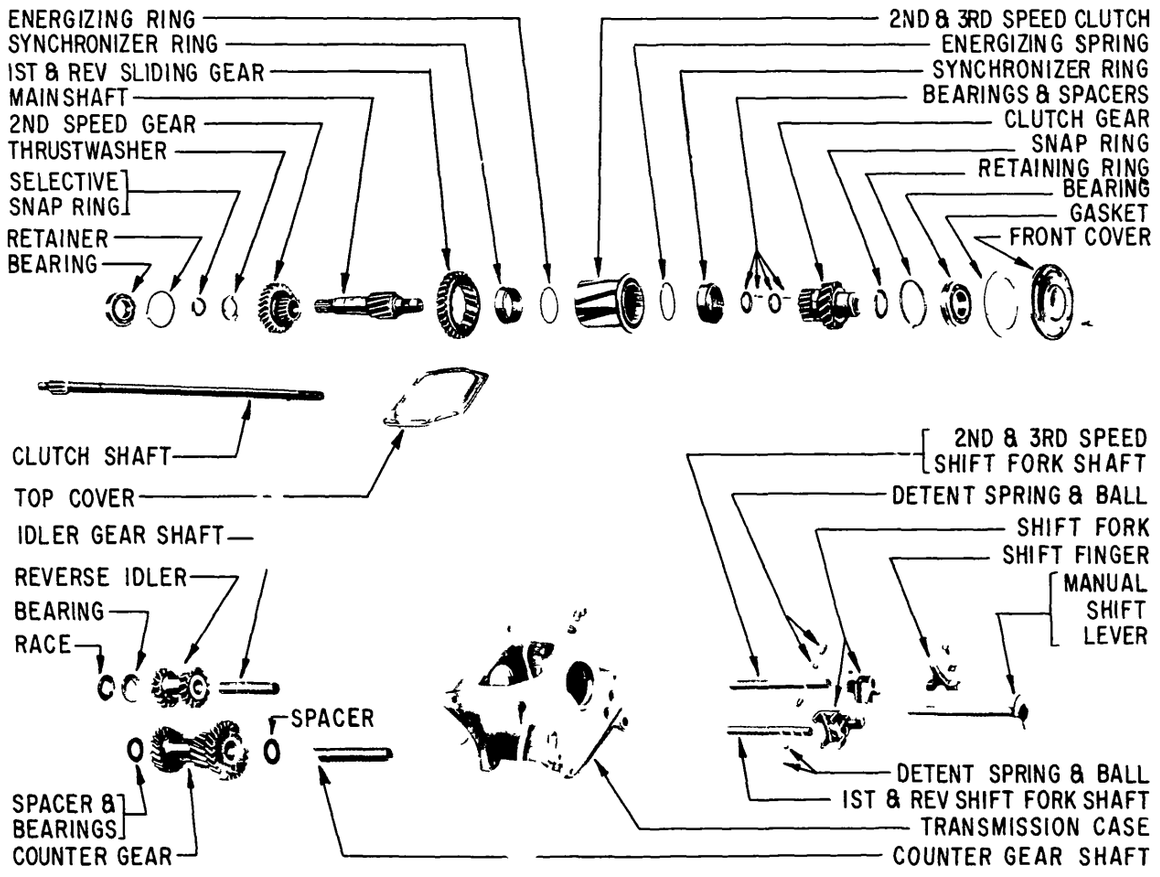
Thrust Spacer Chart

Indicator Reading	② Spacer Thickness
.011-.038" ①	None
.039-.053"	.016"
.054-.068"	.031"
.069-.083"	.046"
.084-.098"	.062"
.099-.113"	.077"
.114-.128"	.092"
.129-.145"	.108"
.146-.155"	.124"

① - If initial indicator reading is below .011", replace .088" thrust washer at clutch hub (front pump) with .076" or .050" thrust washer, then repeat entire rear thrust spacer selection procedure

② - Thrust spacers are furnished in the following thicknesses .016" (Part No 6256827), .031" (Part No 6256828), .046" (Part No 6255664) Note that spacer thicknesses required are obtainable with combinations of the three thrust washers furnished for service

DIFFERENTIAL CARRIER: Removal & Installation - *See instructions above for "Synchro-mesh" or "Powerglide" Transmissions*



SYNCHRO-MESH TRANSMISSION OVERHAUL

DISASSEMBLY: With transmission removed from differential carrier, proceed as follows

1) Mount transmission in Holding Fixture J-7896, then remove front cover plate and clutch gear bearing snap ring

2) To remove clutch gear and bearing, disassemble Tool J-8361 and install the adapter and screw assembly in slot in clutch hub Place dome over adapter and screw, being sure to index dome locating pins into screw holes in transmission case Loosen screws securing bearing snap ring fingers on dome assembly and place fingers between open ends of snap rings, then fully open snap rings with pliers Tighten finger screws to retain screws fully expanded *CAUTION - Before*

CONTINUED ON NEXT PAGE

CORVAIR SYNCHRO-MESH TRANSMISSION (EXPLODED)

SYNCHRO-MESH (Continued)

opening snap ring, be sure ends are fairly well centered in recess in case. If ring is expanded when ring ends are against either side of recess, the snap ring radius can "hang" in bearing groove and result in a broken case when bearing is pulled. Pull bearing and clutch gear by turning nut while holding screw on puller. *NOTE - Needle bearings will fall out when clutch gear removed.*

3) Remove case top cover and gasket, then remove snap ring from mainshaft groove (snap ring is immediately behind mainshaft bearing). Drive or press mainshaft out of case. Remove thrust washer, second speed gear, sliding gear, and second and third speed clutch from case.

4) To remove mainshaft bearing from case, fully expand its snap ring and tap bearing out by driving on outer race. Remove countergear by driving out countershaft with Tool J-5777 from hole in front of case.

5) If reverse idler is to be replaced, drive idler shaft lockpin into shaft, then drive shaft out of case with a drift from the "through hole" at rear of case. *NOTE - The expansion plug at front of case will be driven out by reverse idler shaft.* Remove caged needle bearing and thrust washer used at rear of reverse idler.

6) Remove detent cover and remove second and third gear detent spring and ball. Drive out roll pin securing second and third shift fork to shaft, then tap out shaft with a drift to remove both fork and shaft. Remove interlock from detent cavity with a magnet, then remove first and reverse shift fork and shaft in same manner as second and third fork. Remove first and reverse detent ball and spring, then remove two capscrews and lock tabs securing shift finger to manual shift rod and pull rod from case.

Clutch Sl v s & Synchronizer Rings (Disassembly & R ass mbly): Remove first and reverse sliding gear, then turn synchronizer ring in clutch sleeve until ends of ring retainer can be seen through slots in clutch sleeve. Use Tool J-0932 and expand retainer into counterbore in clutch sleeve, then slip synchronizer ring out of sleeve. Check cones for wear or for being loose in clutch sleeve. *NOTE - If cones are damaged it will be necessary to replace clutch sleeve assembly and both synchronizer rings. Replace clutch sleeve if ther is more than .030" endplay between cone and snap ring.* Inspect rings for smoothness, then place rings in synchronizer cones and check with thumbs to see that rings do not rock. Install synchronizing ring retainers in counterbores in end of clutch sleeve, then use Tool J-0932 in slot in clutch sleeve and expand each retainer in counterbore. Lubricate each synchronizer ring with light oil and install in clutch sleeve. *CAUTION - Make sure retainers seat in groove all the way around rings so rings will turn freely.* Install first and reverse sliding gear on clutch sleeve.

INSPECTION: Wash all parts in clean solvent and blow dry with air. Check bearings for roughness and replace if necessary. Inspect case for cracks and inspect machined surfaces for burrs. Dress burrs off with a flat file. Inspect all gears and replace any that are worn or damaged. Make sure first and reverse sliding gear slides freely on clutch sleeve and that clutch sleeve slides freely on mainshaft. *NOTE - If reverse idler gear bushings are worn or damaged, replace entire assembly. Gear and bushing are not serviced separat ly.* Proper clearance between idler gear bushing and shaft is .002-.004".

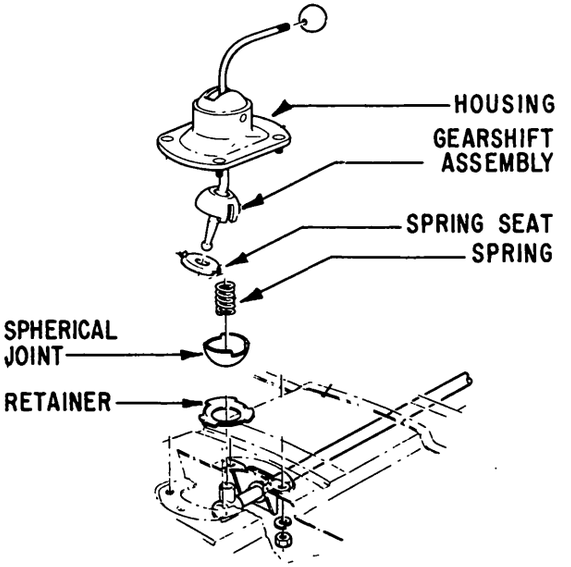
►*SYNCHRONIZER ENERGIZING SPRING CAUTION:* If these springs have been removed, new springs must be installed. Assemble each spring in its groove in clutch gear and second speed gear with offset or locking end of spring between the third and fourth teeth of either of the two banks of teeth on these gears, thus keeping spring from turning in its groove. *CAUTION - Spring must be carefully installed so as not to expand it greater than the diameter of the gear teeth as spring will take a "set".*

REASSEMBLY: 1) Oil manual control shaft and insert through seal in case, then position actuating finger and secure to shaft with two lock tabs and capscrews. Bend lock tabs onto heads of screws. Install detent spring and ball in detent cavity, then tap ball and spring to make sure spring is resting on bottom of cavity.

2) Insert first and reverse fork shaft through case, slip fork on shaft and secure fork to shaft with roll pin. Install interlock in detent cavity, then insert second and third fork shaft through case and slip fork onto shaft. Twist shaft so its interlock groove is 90° from interlock, then fully insert shaft and twist shaft so interlock notch is engaged by interlock. Secure shift fork to shaft with a roll pin. Insert detent ball and spring for second and third shift fork, then install detent cavity cover and gasket.

3) Install 25 needle bearing rollers in each end of countergear, holding them in place with cup grease, then install Tool J-5777 in countergear. Lubricate bearing thrust washers and place one at each end of countergear, positioning it so tab on washer will align with notches in case. Install countergear in case and allow it to rest on the bottom. Lubricate and insert countergear shaft in case, then align countergear with shaft being sure thrust washer tabs engage case notches and tap shaft through, pushing assembly Tool J-5777 out of case. Countershaft is a slight press fit at front of case. *NOTE - Final installed position of "flat" on shaft is not important.*

4) Lubricate thrust washer and needle thrust bearing with grease and position them on reverse idler gear (needle bearing against end with chamfered teeth). Lubricate bushings, then place gear assembly in position in case so thrust bearing is toward rear. Install idler shaft from rear, making sure lockpin hole in shaft lines up with hole in case at the same angle. Drive a new lockpin in so it is approximately 1/16" beyond flush with case.



5) Install mainshaft rear bearing in case by tapping on outer diameter of bearing until it contacts retainer ring in case, then expand retainer and tap bearing until retainer ring seats in bearing groove. Install sliding gear on second and third speed clutch, then install second speed gear in second and third speed clutch. Place this assembly in case, then from the front, insert mainshaft through bores of second and third speed clutch and second speed gear. Install thrust washer on mainshaft with its oil grooves toward gear. Tap front of mainshaft until ring groove is accessible behind rear bearing and install snap ring.

6) Check fit of snap ring at front of mainshaft (previously installed) by inserting feeler stock between snap ring and bearing inner race. Final end clearance must be .004" maximum. If endplay is not within limits, thrust washer on mainshaft must be changed to obtain correct endplay. *NOTE* - Washers are available in four thicknesses ranging from .086" to .097".

7) Place cup grease in mainshaft pilot hole of clutch gear and install roller bearings and small spacer, then install large spacer and remaining roller bearings. Align synchronizer lands with clutch gear blank teeth, then install smaller snap ring in clutch gear. Tap clutch gear bearing into case, then open retainer ring and fully seat bearing as indicated by seating of retainer ring in bearing groove. Install front cover plate and gasket and tighten the screws. Install top cover. Install expansion plugs in case openings at rear of manual shaft and reverse idler gear shaft.

GEARSHIFT LEVER ASSEMBLY: Removal - Remove tunnel front plate, then remove four nuts securing gearshift lever assembly to floor pan. *NOTE - Two r ar nuts also secure shift control shaft front mounting bracket.* From the driver's compartment, lift gearshift lever assembly up until its studs clear floor pan, then remove unit by lifting floor mat at center of seat.

Disassembly: Remove knob, then clamp housing in a vise. Use a length of 1½" pipe or Tool J-5590 and depress retainer plate and rotate until its three lugs clear lands in gearshift housing, then remove retainer. Remove lower spherical joint, spring, and seat, then pull lever out of housing.

SYNCHRO-MESH GEARSHIFT LEVER ASSY.

Reassembly: Apply Lubriplate generously to all working surfaces, then place retainer plate on lower spherical joint and place housing in a vise. Place seat on gearshift lever with tab to right side of housing, then compress retainer and rotate laterally to engage its lugs in housing (use same tool or 1½" pipe used at disassembly). Install knob.

Installati n: Reverse removal procedure.

CONTINUED ON NEXT PAGE

SYNCHRO-MESH (Continued)

SHIFT CONTROL ROD: Removal - With tunnel cover removed, fold back rubber boot covering control shaft U-joint to expose connecting pin. Remove cotter pin, then remove connecting pin by pushing out with channel lock pliers. Separate control shaft U-joint from transmission shifter shaft by pushing control shaft toward front of car. Complete removal of control shaft by removing two nuts attaching control shaft front mounting bracket, then remove control shaft, U-joint, and mounting bracket as an assembly.

U-Joint Replacement: To insure maintaining shift control adjustment, scribe the control shaft adjacent to end of U-joint, then loosen clamp bolt and remove old U-joint and rubber boot. Insert new U-joint, with rubber boot installed, in shift control shaft until end of U-joint is aligned with mark scribed at removal. Rotate U-joint so attaching pin hole at transmission end is vertical, then tighten clampscrew.

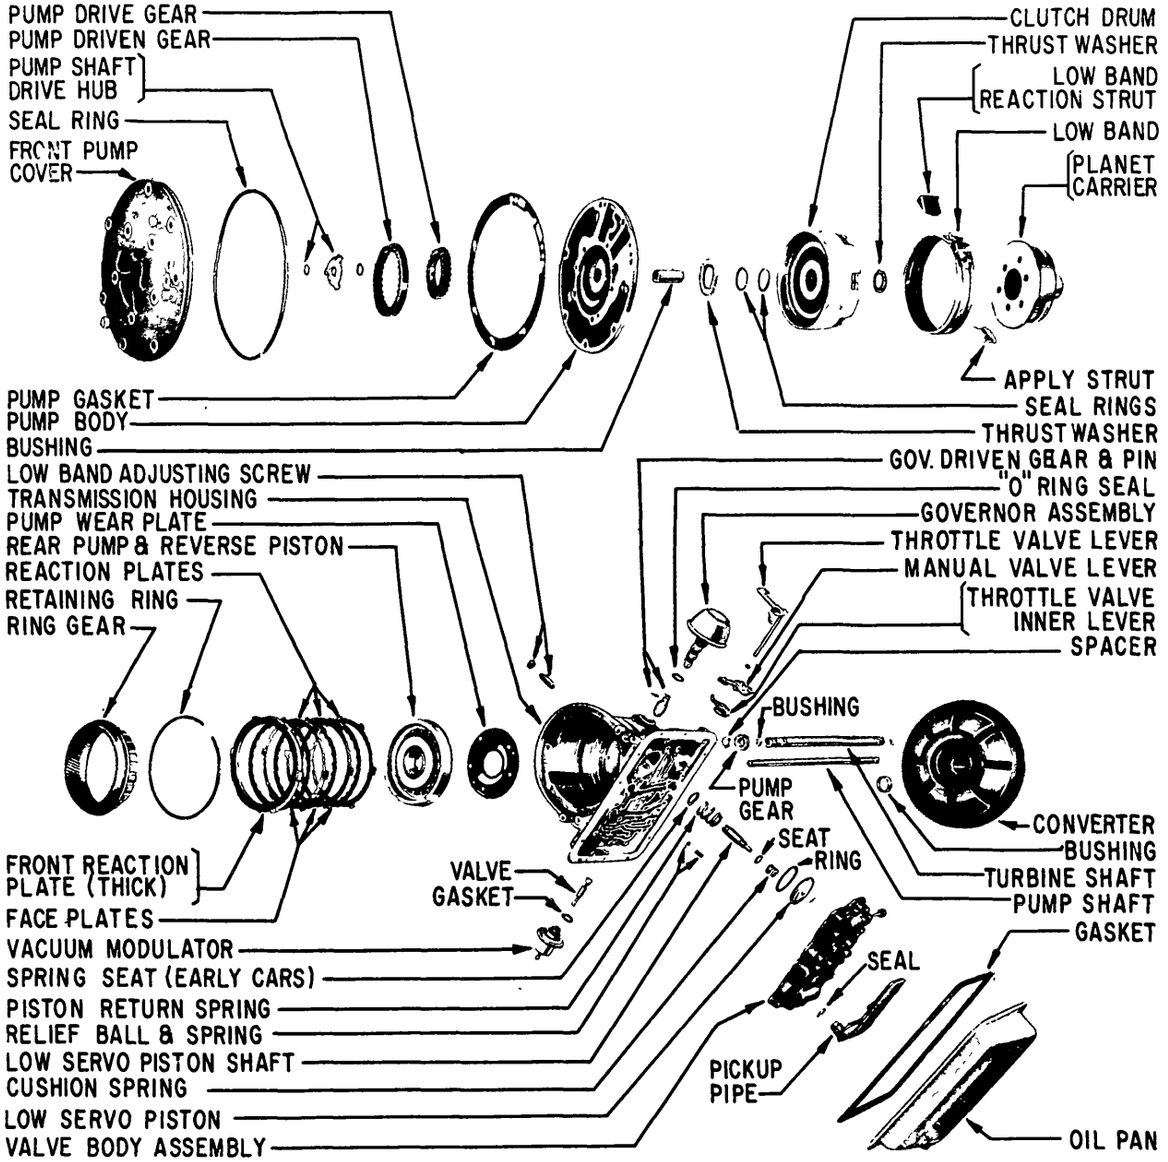
Mounting Bracket or Bushing Replacement: Remove U-joint, then slide bracket off control shaft. Nylon bushing in bracket is "push-in" type. Reinstall bracket with reinforced side toward rear of shaft, then install U-joint.

Installation: Center shift lever ball, position and align control shaft front bracket with rear shift lever stud, then insert bracket on its studs simultaneously with insertion of control shaft ball socket onto shift lever ball. *NOTE - Control shaft socket should be well coated with lubriplate before installation.* Secure shaft bracket in position with two nuts. Align control shaft U-joint with transmission shifter shaft, then pull U-joint over shifter shaft and install connecting pin and secure with cotter pin. Snap boot of shifter shaft seal into place in tunnel rear plate.

POWERGLIDE TRANSMISSION

►*1960 CORVAIR REAR PUMP CHECK VALVE PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* A new rear pump check valve assembly, Part No. 3783780, having a spring loaded poppet valve is being used in later production and should be installed in earlier transmissions at time of overhaul. The new type check valve eliminates momentary no-drive conditions resulting from loss of rear pump prime when car is backed up.

TRANSMISSION UNIT REMOVAL (TRANSMISSION IN CAR)



►*NOTE: The following units can be removed with transmission in car.*

CONTROL CABLE (MANUAL SHIFT): Removal - Disconnect control cable from range selector by removing the "E" retainer. Remove nut securing control cable to its attaching bracket on range selector and free cable from selector. Remove tunnel covers, then, at front of car, remove cable from multiple clip at toe-pan and remove upper toe pan clip. Remove cable from clips in tunnel, then remove grommet plate at rear of tunnel. Free cable sheath from plate and remove clip in underbody kick-up area. Disconnect throttle rods from lever on transmission. Complete cable removal by rotating transmission throttle valve lever its full limit counterclockwise to free cable ball from the inner manual valve lever slot in transmission and withdraw cable. Bow cable towards center line of car to guide cable through hole in engine front support.

►*CABLE REPLACEMENT NOTE: Cable assembly (with its two captive grommets) is serviced only as a complete unit.*

Installation: With tunnel covers removed, lay cable out beneath car in its correct relationship, then insert front of cable up into passenger compartment. *CAUTION - Cable must be routed UNDER the parking brake cable and OVER the brake pipe to prevent brake cable riding against shift cable.* Connect shift cable to range selector by inserting it into its mounting bracket, then while holding sheath nut with a wrench, install sheet metal nut on threaded portion of sheath to secure cable to bracket. *CAUTION - Be sure that the flat on cable sheath is flush when cable is installed.* Shift range selector to "D", then attach cable upper clip in toe-pan and secure cable in multiple clip at base of toe-pan. Be sure rubber protector is installed on clip. Secure cable with three clips installed in tunnel, then bow cable towards center line of car to guide cable through hole in engine front support. On cars with early type design cable-to-case installation, rotate throttle lever on transmission to its full counterclockwise limit and

CONTINUED ON NEXT PAGE

POWERGLIDE TRANSMISSION INTERNAL PARTS (EXPLODED)

POWERGLIDE (Continued)

insert cable ball into slot of transmission manual lever while guiding cable sheath stop into slot. Insert and tighten sheath nut to 8-10 ft. lbs. *CAUTION - Overtightening can crack case at this area.* On cars with later type design cable-to-case installation, install "O" ring seal on cable and lubricate lightly with Lubriplate. Rotate throttle valve lever to its full limit counterclockwise and insert cable ball into slot of manual valve lever. Fully seat "O" ring and secure installation by installing capscrew and washer. To check installation, exert a slight hand pressure in counterclockwise direction and check that the hole in notched arm of throttle valve lever is BELOW the transmission oil pan rail. If hole is above pan rail, cable installation is not correct. When installation is correct, install cable rear grommet in grommet plate, then install grommet plate in rear of tunnel. Install clip on cable at rear kick-up area, then check operation of shift linkage.

VACUUM MODULATOR: Located on right side of transmission and serviced from beneath car.

Removal: Remove hose at vacuum modulator, then unscrew modulator using channel lock pliers or a thin 1" wrench.

▷*NOTE: Vacuum modulator is not repairable and must be replaced as an assembly.*

Installation: Reverse removal procedure making sure that a new gasket is used and that it is held in a centered position during installation.

GOVERNOR: Located on left side of transmission and serviced from beneath car.

Removal: Remove governor tab lockscrew and pull governor from case.

▷*NOTE: The driven gear is the only part that is replaceable on governor. To remove gear, drive out pin with a punch and pull out old gear. To install, drill a new hole 90° from original hole, then insert new gear and install roll pin.*

Installation: Install new "O" ring seal, then reverse removal procedure.

VALVE BODY & LOW SERVO: Removal - Disconnect throttle valve rod from transmission lever, then remove oil pan and remove oil pick-up pipe. Improvise a sheet metal strap to fit across the corner of transmission case in the area of the low servo and secure in position with one pan screw. Remove bolts securing valve body to transmission, then tap body lightly with a soft hammer to loosen it from dowels in case. Carefully lower valve body about 1/16", then rotate improvised strap into position so it spans the servo piston hub and secure strap with a second pan screw. *NOTE - This will eliminate possibility of servo piston slipping down out of its bore and the loss of low band engagement with its apply components.* To remove low piston, pull downward on hub of piston shaft with a screwdriver. *CAUTION - Do not remove piston in car without fully tightening low band screw.*

Disassembly, Inspection & Reassembly: *See "Valve Body & Low Servo" under "Overhaul" below.*

Installation: Install low servo piston and return spring in bore in transmission and engage notch in piston shaft with low band apply strut, loosening low band screw slightly to permit piston ring to seat in case bore. If low band was fully tightened to permit removal of low servo, install valve body in transmission while simultaneously loosening low band screw until it is possible to index valve body on dowels in case. If only valve body was removed and an improvised strap was employed, raise valve body almost onto mating surface in case, then rotate improvised strap out of way and secure valve body. If manual valve is installed, index it with manual valve lever in case, then secure the valve body with 20 bolts and tighten to 9-11 ft. lbs. Install "O" ring seal in valve body, then install oil pick-up pipe and secure with screw. Use a new gasket and install transmission oil pan, tightening screws to 3-4 ft. lbs. Tighten filler tube attaching nut and refill transmission. *NOTE - If low band adjustment was disturbed, adjust band (see "Adjustment" above).*

OVERHAUL
(TRANSMISSION OUT OF CAR)

▷*TRANSMISSION OVERHAUL NOTE: All of the following operations, except those covering the Reverse Clutch Assembly, can be performed with "Power Train" removed from car but not separated into individual units.*

DISASSEMBLY

▷*NOTE: Instructions below cover removal of subassemblies from transmission case. See "OVERHAUL OF UNITS" for disassembly, inspection, and reassembly of these units.*

1) If transmission is separated from power train, mount transmission in holding fixture J-7896. If assembled to power train, drain transmission and remove filler pipe. Remove oil pan, pick-up pipe, control valve and servo, vacuum modulator, and governor assembly (for removal procedures, *see "Transmission Unit Removal & Installation - Transmission in Car" above). NOTE - If transmission is installed on power train, loosen low band adjusting screw locknut and FULLY tighten the adjusting screw.* Remove front pump-to-case bolts, then use slide hammer J-6585 and adapters J-8365 and free pump from case. *NOTE - Adapters may be installed in any of the five inner mounting bolt holes.*

2) Remove front pump cover, then remove pump shaft, being careful not to damage bushings in front pump body and turbine shaft with pump shaft splines. Remove pump body from case, being careful not to drop gears, then remove gasket.

3) To remove clutch drum, loosen low band adjusting screw and remove low band, apply strut, and reaction strut, then remove drum. *CAUTION - If transmission is connected to power train, care should be taken not to disengage the ring gear from reverse clutch face plates unless replacement of either ring gear or reverse clutch plates is anticipated. Engagement of reverse plates and ring gear while in a horizontal position is difficult and should not be attempted unnecessarily.*

4) Remove planet carrier from ring gear and remove turbine shaft. *NOTE - Turbine shaft removed previously if transmission is separated from power train.*

5) *NOTE - The remaining disassembly procedures can only be performed with transmission separated from power train.* Remove ring gear from its engagement with rear clutch plates, then remove clip mounted on thick reverse reaction plate between ends of reverse clutch snap ring, then remove snap ring. Remove thick reaction plate, three faced drive plates, and the thin steel reaction plates.

6) Remove rear pump and reverse piston mounting bolts which are accessible from rear (differential side) of transmission case. Remove rear pump and reverse piston assembly by pulling forward with a twisting action. Remove rear pump wear plate from rear of transmission case.

TRANSMISSION UNIT OVERHAUL

TRANSMISSION CASE: Inspection - Inspect all mating surfaces of case for nicks or burrs and repair as necessary. Check for cracks, being especially careful to check area around manual shaft cable (early design case) as overtightening of cable nut could possibly crack the case at this point. Check case bores for wear and grooves.

CONTROL VALVE: Disassembly - 1) Remove two clutch head screws attaching hydraulic modulator valve body and separate modulator body from main body. *CAUTION - Modulator body is under spring tension.* Remove pressure regulator valve spring retainer, spring, and pressure regulator valve.

2) Remove rear pump priming ball, front and rear pump check valves and springs and the modulator valve from modulator valve body. Drive roll pin from hydraulic modulator valve with a pin punch and remove pressure limiting valve spring and valve.

3) Remove two remaining clutch head screws and separate transfer plate and gasket from main body. To remove low drive shift valve components, remove retaining ring with Truarc pliers while exerting a downward pressure, then release pressure and remove low drive regulator valve sleeve, regulator valve, spring seat and inner and outer springs. Lightly tap main body with a plastic hammer to remove low drive valve from its bore.

4) To remove throttle valve components, remove retaining pin by wedging a thin screwdriver between its head and surface of main body, then remove detent valve assembly and throttle valve spring. Complete disassembly by removing the "E" ring from throttle valve, then remove throttle valve from main body bore by tapping body with a plastic hammer.

Inspection: Clean all parts thoroughly, then check valves and their operating bores for burrs or other deformities.

Reassembly: 1) Drop line pressure limiting valve into its bore, then install spring. Compress spring slightly and secure in place by installing roll pin. Install hydraulic modulator valve in its bore in modulator valve body, then place rear pump priming ball and front and rear pump check valves into modulator body.

2) Carefully lower transfer plate onto assembled units in hydraulic modulator valve body so as not to knock front and rear pump check valves from their springs, then secure transfer plate to modulator valve body with two clutch head screws. Tighten screws to 38-50 inch pounds.

3) Install low drive shift valve components into main valve body. Place low drive shift valve into its main body bore, then assemble the inner and outer drive springs and place them in the bore, Insert low drive regulator valve into regulator valve sleeve, then place spring seat over open end of regulator valve sleeve, and insert this assembly into bore in main valve body, compressing the inner and outer springs. Secure in position by installing retainer ring with Truarc pliers.

4) Install throttle valve into its bore in main valve body, then install locating ring in groove in throttle

CONTINUED ON NEXT PAGE

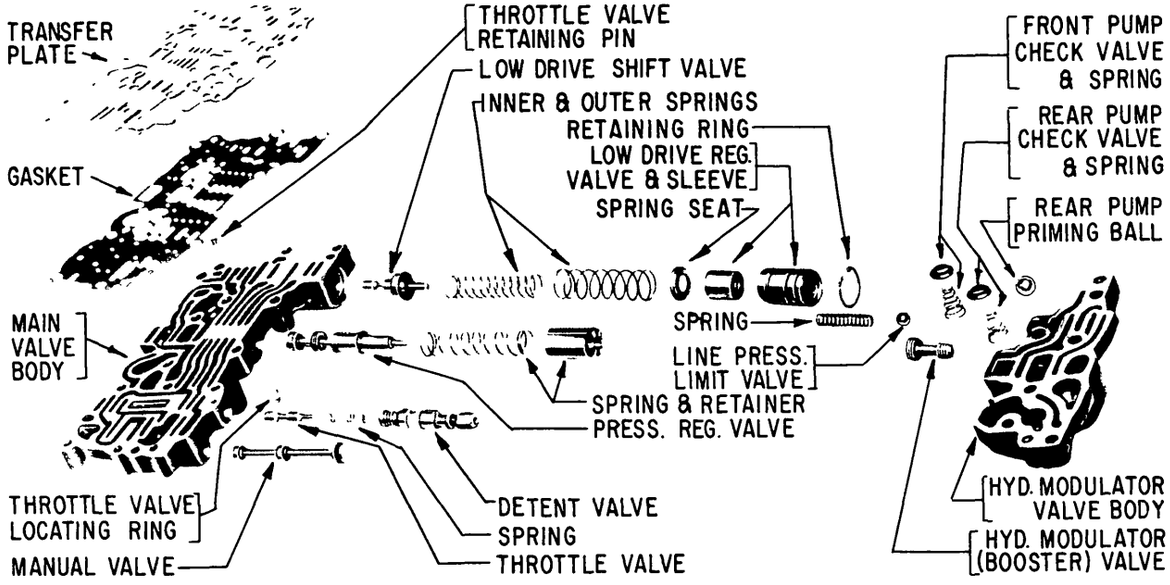
POWERGLIDE (C ntinu d)

valve. *CAUTION - Be sure throttle valve is fully seated in its bore as locating ring must be installed in throttle valve through the third port from left of valve (as viewed in illustration).* Place throttle valve spring and detent valve assembly in throttle valve bore, then depress detent valve assembly and secure to valve body by tapping retaining pin into main valve body.

5) Apply a light coat of petrolatum to main valve body and install a new gasket. Install pressure regulator valve in main valve body with spring and spring retainer. Fully compress pressure regulator valve spring so that spring retainer enters bore of main valve body, then position main valve body onto transfer plate (assembled to modulator body) and align mounting screw holes. Install two remaining clutch head screws and tighten to 38-50 inch pounds. Install manual valve in main valve body, then check shift cable (linkage) adjustment.

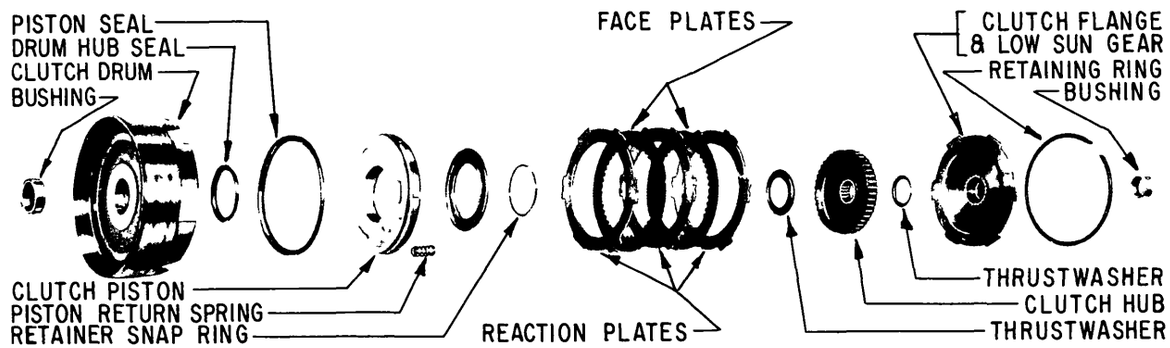
LOW SERVO PISTON: Disassembly - Remove hairpin retainer securing piston to piston rod and separate all components. Remove piston ring from piston and install it in low servo bore of transmission case, then measure end gap of ring. Gap should be .002-.012". Assemble ring to piston and measure clearance between ring and one wall of piston groove. This clearance should be .0005-.005".

R assembly: Place spring seat on piston shaft, then install cushion spring. Compress cushion spring slightly with piston and secure to shaft with hairpin retainer.



FRONT PUMP: Inspection - Wash all parts in solvent and blow out all passages. *CAUTION - Do not use rags to dry parts.* Inspect pump gears for nicks or damage. Check for wear at gear bearing surfaces on inner diameter where it mates with pump journal. Inspect cover and body for nicks or scoring. Install pump gears and check following clearances: Between outer diameter of driven gear and body which should be .0025-.005". Between driven gear and crescent which should be .003-.009". Use a scale and a feeler gauge and check gear end clearance which should be .0005-.0015". Inspect pump drive gear teeth for interference between tops of teeth and crescent in pump. Replace gasket and square cut seal ring in outer diameter of pump cover. Make sure cast iron seal rings on pump body hub are in good condition. Replace if necessary. Check condition of pump body bushing. If worn or damaged, replace bushing.

Fr nt Pump Body Bushing Replacement: Remove bushing with a chisel, being careful not to damage pump body. Install a new bushing with Tool J-8360-5 and an arbor press.



CLUTCH DRUM: Disassembly - 1) Remove retainer ring securing low sun gear and clutch flange assembly to clutch drum. Remove low sun gear and clutch flange, and hub rear thrust washer. Lift out clutch hub, then remove the nested drive and reaction plates and hub front thrust washer.

2) To remove spring retainer, place clutch drum in a press and compress springs using Tool J-7782 (adapter ring) and J-5133. Remove snap ring with Truarc pliers. Carefully release pressure on press, then remove spring retainer and springs.

3) To remove clutch piston, pull upward with a twisting motion on center, then remove piston seal. Remove piston inner seal from hub on clutch drum.

CORVAIR POWERGLIDE VALVE BODY ASSEMBLY

CORVAIR POWERGLIDE CLUTCH DRUM ASSEMBLY

Inspection: Wash all parts in solvent and blow dry with air. *CAUTION - Do not use rags to dry parts.* Inspect drum brake band surface for scoring or burning and check drum bushing for scoring or excessive wear. Check steel ball in clutch drum that acts as a relief valve. Be sure that it is free to move in hole and that orifice leading to front of drum is open. *NOTE - If relief ball is loose enough to come out or not loose enough to rattle, replace clutch drum as an assembly. DO NOT attempt to replace or restake the ball.* Check fit of clutch flange in drum slots. There should be no appreciable play betwen these two parts. Check low sun gear for nicks or burrs and bushing for wear. Check clutch plates for burning, pitting or metal pickup. Check to see that plates (faced) are a free fit over clutch hub and that steel plates are a free fit in clutch flange. Check for excessive wear on friction facing or drive plate teeth. Check condition of clutch hub splines and mating splines on faced plates.

Clutch Drum Bushing Replacement: Remove old bushing with a chisel being careful not to damage bushing bore. Install new bushing with Tool J-8360-2.

Low Sun Gear Bushing Replacem nt: Remove old bushing with a chisel being careful not to damage bushing bore. Install new bushing with Tool J-8360-3.

Reassembly: Install piston inner seal in hub of clutch drum. *NOTE* - Make sure seal lips are downward or toward front of transmission. Install new piston seal in clutch piston (seal lips toward clutch drum when installed). Lubricate both seals, then install clutch piston in clutch drum with a twisting motion. Place the 15 return springs in position on clutch piston, then place spring retainer on springs. Place clutch drum in an arbor press, position snap ring on clutch drum hub, then compress springs using Tool J-5133 and J-7782. With springs fully compressed, install snap ring in

CONTINUED ON NEXT PAGE

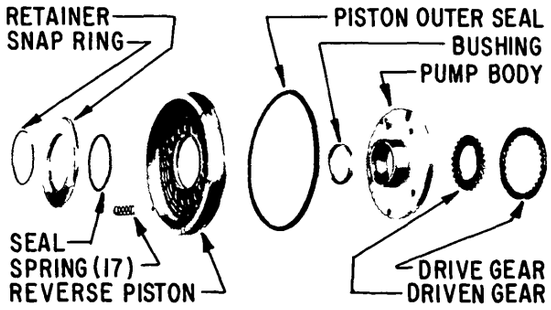
POWERGLIDE (C ntinu d)

groove on clutch drum with Truarc pliers, Install hub front thrust washer with its lip toward clutch drum, then install clutch hub, Install three reaction plates and two faced drive plates alternately, starting with a steel reaction plate. Install hub rear thrust washer with its flange toward low sun gear, then low sun gear and clutch flange assembly and secure in place with retainer ring. *NOTE - Finally installed, openings of retainer ring should be adjacent to one of the lands of clutch drum.* Check the assembly by turning clutch hub to be sure it is free to rotate.

PLANET CARRIER: Service by replacing as a complete assembly.

TURBINE SHAFT: Insp ction - Check shaft for nicks and cracks and check splined area for wear. Check to make sure that the two lubrication holes are open. Inspect bushings and, if necessary, replace.

Bushing R plac m nt: *NOTE - The two bushings are id ntical, howev r the d pth to which they are installed is diff rent.* To remove old bushing, cut it out with a chisel being careful not to damage the bore. Install front bushing with Tool J-8360-6, and rear bushing with J-8360-7.



PUMP SHAFT: Inspection - Check splines at converter end of shaft for wear or damage. Inspect bronze faced drive lugs for peened edges and wear of its splined connection to shaft by twisting to check for looseness. Make sure drive hub is tightly retained by snap ring. *NOTE - If bronz driv hub is worn, remove top snap ring and r plac hub.*

REAR PUMP & REVERSE PISTON ASSEMBLY: Disassembly - Remove drive gear and driven gear from pump body, then place the assembly in a press with pump body on wood or other soft material and compress spring retainer with Tool J-7782 and J-5133. With spring retainer compressed until springs bottom, remove snap ring. Carefully release pressure, then remove spring retainer and return springs. In order to remove reverse piston, it is necessary to fill groove for snap ring in hub of rear pump body with string, a small rubber band, or a similar size "O" ring. With groove filled, rear pump body can be pushed out of reverse piston bore. Remove square cut piston inner seal and piston outer seal. *NOTE - Install new seals at reassembly.*

Insp cti n: Wash all parts in clean solvent and blow dry with air. Check fit of rear pump drive and driven gears in same manner as for front pump (*see "Front Pump" abov*). Inspect pump body for scores and leakage. Check hub of pump body for smoothness. Check for broken piston return springs and make a comparative check of spring heights by standing all of the springs in a row. If there is an appreciable difference in spring heights, replace springs. Check condition of rear pump body bushing and replace if scored or worn.

Rear Pump B dy Bushing R placement: Remove old bushing with a chisel being careful not to damage bore. Install new bushing with Tool J-8360-4 and an arbor press.

R ass mbly: Install piston inner seal in reverse piston, then install outer seal in piston with lip of seal toward pump body (opposite from spring seats in piston). Install reverse piston on rear pump body (it is not necessary to fill groove on pump body hub for installation). Position 17 return springs in their seats on reverse piston, then place spring retainer on springs. Place

POWERGLIDE REAR PUMP & REVERSE PISTON

unit in a press with wood between press bed and rear pump body. Place snap ring on hub of rear pump body and compress springs using same tools and procedure used at disassembly. With springs fully compressed, install snap ring in its groove in pump body. Install drive gear and driven gear in their respective bores in pump body. *NOTE - Apply a small amount of petrolatum to pump gears to prevent their being dropped from body.*

CONVERTER: Inspection - *NOTE - It is not necessary to drain converter as it is a welded unit and cannot be repaired.* Check starter gear for worn or broken teeth and for broken welds at its attachment to converter assembly. If starter gear is not damaged but welds are loose or broken, reweld as necessary. Check converter seams for stress or breaks and either replace converter or repair welds as required. *NOTE - If welds are repaired, keep added material to a minimum by carefully chipping off all scale and filing away any unnecessary weld to retain converter balance as close to original as possible. Replace converter if roughness due to unbalance is noticed after installation on engine.*

Converter Bushing Replacement: Remove old bushing with a chisel, then install new bushing with Tool J-8360-1, driving it into place with a hammer.

REASSEMBLY

1) With transmission installed in holding fixture, install two improvised pins (5/16" - 18, about 2½-3" long) in rear pump bolt holes, then install rear pump wear plate on guide pins. *NOTE - Use a small amount of petrolatum to hold plate in place.* Insert rear pump and reverse piston with guide pins into case, then insert a length (½" to ¾" wide) of shim stock, .010-.015" thick, between piston outer seal and case. With rear of case downward, running the shim stock around entire diameter of seal will seat seal quickly. Remove guide pins and install five rear pump mounting bolts and tighten to 9-11 ft. lbs.

2) Install reverse clutch drive and reaction plates alternately starting with a reaction plate (steel) and finishing with a drive plate (faced). *NOTE - The notched lug in each steel reaction plate is installed so it is at the TOP of the groove at the "4 o'clock" position in the case.* Then install the thick reaction plate retainer ring in such a manner so that open ends of ring are at the "12 o'clock" position. Install retainer ring clip on thick reaction plate between ends of snap ring.

3) With rear of transmission case downward, align internal lands and grooves of reverse face plates. Engage ring gear to reverse drive plates. *NOTE - Engagement must be made by "feel" while jiggling drive plat s laterally.*

4) On overhaul being done with transmission installed on power train, install the turbine shaft making sure splines of turbine shaft are fully engaged with splines in converter turbine. Install planetary unit with a slight twist to engage planet gears with ring gear. Be sure to engage the two rear pump drive lugs on planet hub with grooves in rear pump drive gear.

5) Install thrust washer on captive input sun gear in planetary gear set with flange of thrust washer toward front of transmission. *NOTE - If necessary, use a small amount of petrolatum to keep thrust wash r centered, especially if assembly is being done with transmission installed on power train.* Install clutch drum assembly using a slight twist to engage low sun gear to planet gears on planetary gear set.

6) If overhaul is being done with transmission disconnected from power train, turn transmission to a horizontal position. Install low band, apply strut, and reaction strut and when in proper position, tighten low band adjusting screw to prevent struts falling out of place. Jiggle clutch drum slightly to center band and linkage.

►*TRANSMISSION OVERHAUL CAUTION:* If transmission is being overhauled while attached to power train, determine the correct thickness of selective thrust washer to be installed on front pump hub. *See "Front Selective Thrust Washer" below.* If transmission is separated from power train, install the original (unless necessary to replace) thrust washer on front pump hub without gauging. Final endplay adjustment will be made at rear selective thrust washer. *See "Rear Selectiv Thrust Washer" under "Powerglide Transmission R - moval & Installation" above.*

►*FRONT SELECTIVE THRUST WASHER: CAUTION - This procedure is absolutely limited to overhauls performed while transmission is assembled to power train.* Insert pilot of Tool J-8371 into bore of clutch drum and secure to case with two front pump mounting bolts. Tighten bolts fully to compress pilot spring. Check that plunger on tool is fully seated, then note plunger position in relation to face of tool. If plunger is **below flush,** a .076" thrust washer is required. If plunger is **flush or above,** a .050" thrust washer is required. Remove tool and install selected thrust washer on front pump hub. Complete reassembly as follows:

7) Install a new front pump gasket, then install front pump body, being careful not to break cast iron rings on pump body hub when they are indexed to clutch drum. Install front pump drive shaft. *CAUTION - Be careful when inserting pump shaft not to damage bushings of transmission components already installed.*

8) Install a new square cut seal ring in front pump cover, then position front cover and install mounting bolts loosely. *NOTE - Dip heads of mounting bolts in a non-hardening sealer.* Tighten outer bolts in a criss-cross pattern to 18-20 ft. lbs., then tighten five inner bolts to 18-20 ft. lbs. Adjust low band by first tightening adjusting screw to 40±5 inch pounds, then back off 4 full turns exactly. Hold adjusting screw and tighten locknut. Install governor assembly, vacuum modulator, control valve and servo, pick-up pipe, and oil pan (for installation procedures, s *"Transmission Unit R - moval & Installation - Transmission in Car" above).*

CONTINUED ON NEXT PAGE

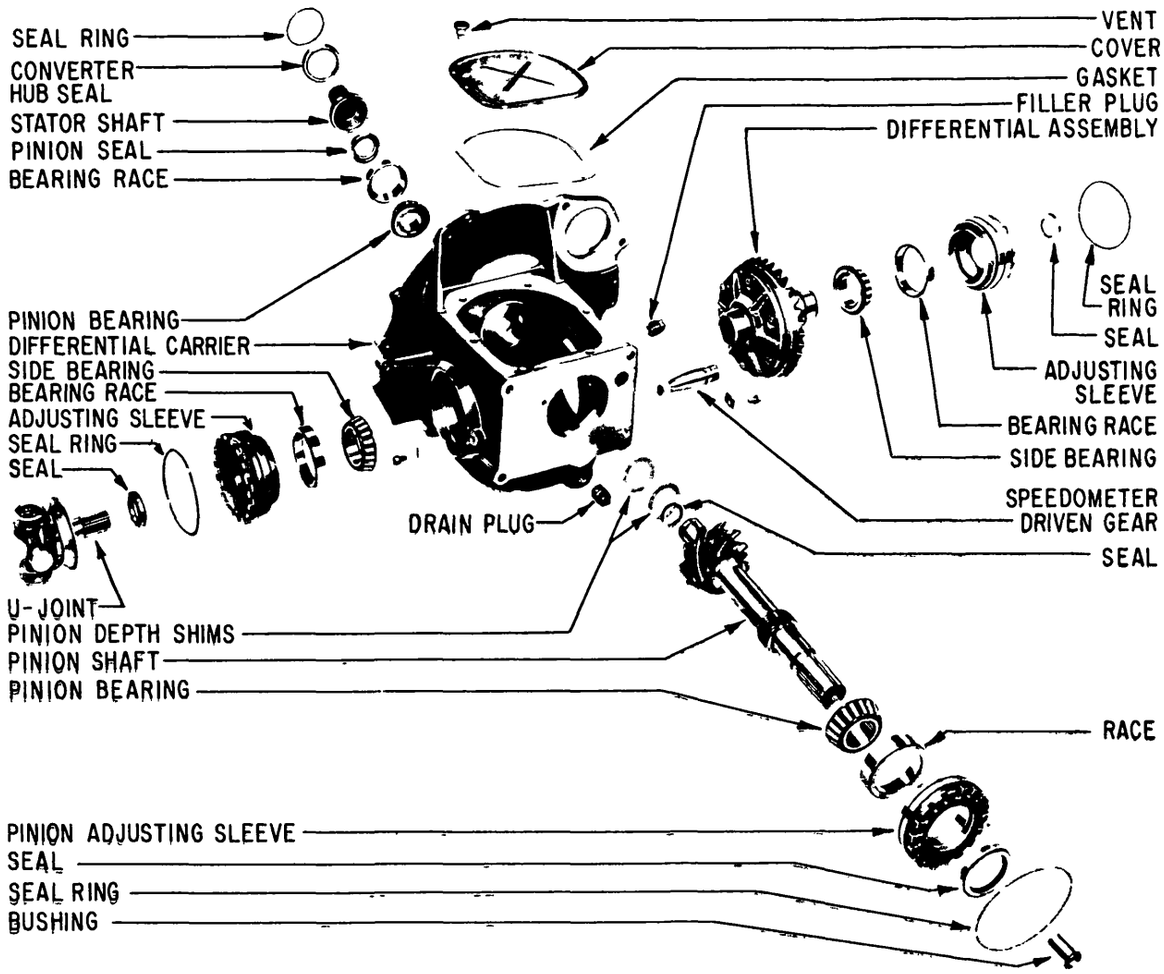
DIFFERENTIAL CARRIER

►*DIFFERENTIAL CARRIER COMPONENT SERVICING NOTE: The following differential carrier components can be serviced with the carrier in its installed position in car.*

AXLE SHAFT: Removal - *See "Rear Axle" on Car Model page.*

Bearing Replacement: Place axle shaft in a press with Tool J-5741 puller plate **below** the puller ring, then remove oil deflector, bearing and puller ring. *NOTE - Reinforcing ribs on Tool J-5741 should be upward for removal operation.* To install a new bearing assembly, place a new puller ring, bearing assembly, and oil deflector on axle shaft. *NOTE - To prevent damaging bearing assembly during installation, place the old puller ring with its flat side against bearing inner race.* Press the new puller ring and bearing assembly onto axle shaft using Tool J-5741 and an arbor press. Remove old puller ring and install oil deflector with closed side of deflector toward bearing.

Axle Shaft Installation: Reverse removal procedure and note the following: If universal joint yoke cannot be tapped onto end of axle shaft, install a 300M steel bolt (3/8-16 x 1½") and original flat washer in shaft and draw joint yoke onto shaft with screw. When screw bottoms, replace 1½" long bolt with a 1" bolt and continue tightening until bolt bottoms. Remove 1" bolt and secure yoke to shaft with original bolt, flat washer, and lock washer.



SIDE BEARING ADJUSTING SLEEVE OIL SEAL REPLACEMENT: Remove universal joint from side bearing adjusting sleeve, then pry out original seal and install a new seal with any flat object (seal mounts flush). *NOTE - Lip of seal must be inward.*

OVERHAUL

CARRIER DISASSEMBLY: 1) With differential carrier removed from power train and transmission removed from carrier (see above), drain oil from carrier, then mount carrier in holding fixture J-3289-01. Loosen locking tab and remove speedometer driven gear assembly.
2) Remove carrier cover from case, then remove capscrew securing locking tab to differential side gear adjusting sleeves with Tool J-8342. To remove pinion adjusting sleeve, remove locking tab and unscrew adjusting sleeve with Tool J-972.
3) Remove pinion drive gear with bearings attached by lifting upward and then removing through cover hole. Remove differential carrier by shifting differential to one side of carrier and then turning 90°. Remove through cover hole.

INSPECTION: Inspect all bearing cups, races and rollers for scoring, chipping or excessive wear. Inspect large end of rollers for wear. On automatic transmission axles, inspect oil seal in stator support and at converter hub for wear or damage. Inspect pinion splines for wear and inspect ring gear and pinion teeth for scoring, cracking or chipping. Check fit of differential side gears in case. Check fit of side gear and universal joint splines. Inspect pinion shaft for scoring or wear and differential carrier for cracks or crossed threads.

OVERHAUL: *Except as noted, the following procedures apply to both three-speed and automatic transmission differential carrier assemblies.*

CORVAIR DIFFERENTIAL CARRIER ASSEMBLY (EXPLODED)

Pinion and/or Bearing Replacement: Remove front and rear pinion bearings with Tools J-8331 and J-358-1 and an arbor press, then remove shims found between pinion rear bearing and pinion. *NOTE - If it is necessary to replace pinion bearings and/or ring gear and pinion, the shim pack required between rear bearing and pinion gear will have to be determined (see "Pinion Setting" below).* Install proper shim pack between rear bearing and pinion gear and install bearing by driving it into place with Tool J-5590 and a hammer. Install front bearing in the same manner.

Pinion Rear Bearing Race and/or Clutch Release Bearing Shaft Replacement (Synchro-mesh Cars): Place differential carrier in an arbor press and press out both clutch release shaft and pinion rear bearing race. *NOTE - If a new clutch release bearing shaft is being installed, first install a new inner seal. See "Clutch Release Bearing Shaft Seal Replacement" below.* Install a new seal ring in groove on outer diameter of bearing shaft and lubricate with petrolatum. Support differential carrier only on boss at clutch release bearing location with a cylinder (Tool J-971), then place bearing race on clutch release bearing shaft and press both into carrier with Tool J-7137. Press until cup is flush with adjacent surface inside carrier.

Pinion Rear Bearing Race and/or Stator Shaft Replacement (Automatic Trans. Cars): Remove stator shaft and pinion bearing rear cup from carrier by placing carrier in a press and pressing downward on end of shaft. *NOTE - If a new stator shaft is being installed, install a new pinion rear oil seal, see "Pinion Shaft Rear Oil Seal (Auto. Trans. Cars) Replacement" below.* Install a new oil seal ring on outer diameter of stator shaft and lubricate with petrolatum. *NOTE - Seal not used on later production stator shafts.* Align notch in stator shaft with drain back passage boss in carrier, then

CONTINUED ON NEXT PAGE

Form 62 A

DIFFERENTIAL CARRIER (Cont.)

place bearing race on stator shaft and press race and shaft into housing with Tool J-7137. *CAUTION - Carrier must be supported only at stator shaft boss. Use Tool J-971 or other suitable tool as bottom support.*

Pinion Front Bearing Race Replacement (Synchro-mesh & Automatic Trans. Cars): Remove old race from pinion adjusting sleeve with a pin punch. *NOTE - On automatic transmission cars, remove the seal.* Install new race in pinion adjusting sleeve with Tool J-7137 and J-7079-2 handle. On automatic transmission cars, install a new seal with Tool J-8340.

Pinion Shaft Bushing Replacement (Automatic Trans. Cars): Remove old bushing from inside diameter of shaft with a chisel or other suitable tool. Make sure bushing mating surfaces in pinion shaft are not damaged. Install a new bushing and drive it into place with Tool J-8333 and a hammer. *NOTE - A stop is provided on tool so bushing is driven to proper depth.*

Pinion Setting: Position carrier housing so pinion rear bearing is downward. *NOTE - If new bearing is being installed, make sure the new bearing race is installed in housing.* Place pinion rear bearing to be used in the assembly in carrier housing and rotate several times to make sure it is seated in bearing race. Insert Adapter Plug J-6266-25 into bore of stator shaft or clutch bearing shaft, then place gauge plate J-6266-5 on rear bearing and insert clamp bolt through gauge plate and adapter plug holes and lightly tighten nut. Hold Adapter Plug J-6266-25 and shift gauge plate fore and aft and then side-to-side to "feel" when clamp screw is as nearly perfectly centered in adapter plug bore as possible. When properly centered tighten clamp nut to 6 ft. lbs. *CAUTION - Gauge plate hole must be properly centered in rear bearing bore before clamp nut is tightened as bearing may cock when clamp nut is tightened.* Place Gauge Cylinder Adapter J-6266-18 in unthreaded portion of side bearing adjusting sleeve bore, then insert Gauge Cylinder J-6266-10 in adapter with plunger and mounting post horizontal. Oscillate gauge body to insure that adapter crescents and body are fully seated in side bearing bores. Place Gauge J-6266-19 on gauge plate so that it is centered beneath gauge body. Loosen clamping screw in gauge and slide plunger back and forth slightly so that it is exactly centered between low point of gauge cylinder and gauge plate. When this position is obtained, tighten screw in plunger and remove plunger. Use a 2" micrometer and measure from bottom of gauge to top of plunger. Record this reading. Check pinion marking stamped on front face of pinion gear and the pinion plunger reading (obtained above) with "Pinion Setting Shim" chart. As an example, if gauge and plunger reading is 1.255" and the pinion gear is marked "15", the figure found in the column marked "15", horizontally opposite the the figure "1.255" in first column will be "15", indicating that .015" thick shim pack is required between bearing and pinion gear. *NOTE - Shims are identified by notches in edge as indicated in table.*

SHIM IDENTIFICATION CHART

Identification Notches	Shim Thickness	Chart Indication
NONE	.006"	6
1	.009"	9
2	.012"	12
3	.015"	15
4	.018"	18

PINION SETTING SHIM CHART

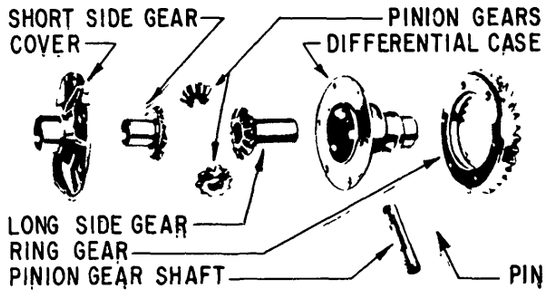
1.261	18	18	18	15+6	15+6	15+6	18+6	18+6	18+6	18+9	18+9



Clutch Release Bearing Shaft Seal Replacement (Synchro-mesh Cars): Remove split ring and oil seal from clutch release bearing shaft by prying out with a punch. Install a new seal, open side inward, using a suitable socket (approx. ¾") and socket extension. Drive seal in until it bottoms, then install split ring in shaft.

Pinion Shaft Front Oil Seal and/or Converter Hub Oil Seal Replacement (Automatic Trans. Cars): Pinion shaft front oil seal and converter hub seal are located opposite each other in fore and aft ends of carrier housing. Installation for the two seals is the same, using the same tool which is designed to install pinion front seal to a prescribed depth and to install converter hub seal which is installed flush. Remove old seal by prying it out with a punch, then coat outer diameter of new seal with non-hardening sealer and drive it into position with Tool J-8340.

Pinion Shaft Rear Oil Seal Replacement (Automatic Trans. Cars): Drive out old seal with punch inserted through access holes in stator shaft. Drive new seal into position with Tool J-5747. Seal must bottom in stator shaft.

Side Bearing Adjusting Sleeve Seal Replacement: Pry out old seal, then install a new seal with lips inward using a flat object as a driver.

Side Bearing Adjusting Sleeve Bearing Race Replacement: Punch mark side bearing adjusting sleeve at two places 9/16" outboard from seal bore 180° apart. Use a 3/16" drill and drill through adjusting sleeve at punch mark locations until drill is stopped by bearing race. Drive out bearing race with a punch. Install new bearing race in sleeve with Tool J-8148 or a suitable flat face for a driver, driving it in flush. Seal drilled holes with lead balls of at least .225" diameter. *NOTE - These balls are available for carburetor repair kits.*

DIFFERENTIAL CASE (EXPLODED)

Differential Gear Assembly Overhaul: Disassembly - Remove differential side bearings with Puller J-7112 and Pilot J-8107-2. *NOTE - Bearing and bearing race should be replaced in sets only.* Remove bolts and lockwashers securing ring gear and differential cover to case and remove cover, short side gear and thrust washer. Tap edges of ring gear with a soft hammer to remove. Drive out roll pin securing differential pinion shaft to case, then tap pinion out of case and remove pinion gears, thrust washers, and long side gear with its thrust washer.

Inspection - Inspect case and cover for cracks. Inspect side gears for fit in case and cover and for evidence of spline damage, broken, scored, or worn teeth. Inspect pinion gears for cracked and chipped teeth and fit on pinion shaft. Inspect all thrust washers for wear. Replace defective parts.

Reassembly - Install side bearings on case and cover with Tool J-5768. *NOTE - Note bearings cannot be installed with this tool after differential is assembled.* Place long side gear and thrust washer in case, position two pinion gears and thrust washers, and insert

CONTINUED ON NEXT PAGE

DIFFERENTIAL CARRIER (Cont.)

pinion gear shaft through case and pinion gears. With flat on pinion shaft upward, install roll pin through case and pinion shaft. Position short side gear, with thrust washer installed on its hub, on pinions and place differential cover on case. Align punch marks on edges of case and cover, then install two improvised guide pins in ring gear and tap gear into place with a plastic hammer. Remove guide pins and install bolts and lockwashers. Tighten to 40-60 ft. lbs. in an alternate pattern.

CARRIER REASSEMBLY: 1) With differential carrier case in holding fixture, insert differential assembly into carrier with side bearing cones installed on differential hubs. While differential is loose in case, install pinion into carrier through cover hole, then engage pinion with ring gear and position pinion rear bearing in race. *CAUTION - On automatic transmission cars, be careful not to damage seal when pinion is installed.*
2) Install new "O" ring seals in side bearing adjusting sleeves, coat adjacent threads with non-hardening sealer, then loosely install adjusting sleeves in carrier with side bearings positioned in sleeves.
3) On automatic transmission cars, install a new "O" ring seal in pinion adjusting sleeve. On all cars, position pinion so that its front bearing will pick up bearing race in adjusting sleeve, then loosely install adjusting sleeve in carrier. *CAUTION - Be careful not to damage seal lips on automatic transmission cars when inserting pinion shaft over adjusting sleeve.*
4) Tighten both side bearing adjusting sleeves and pinion adjusting sleeve to point of contact between bearings and races. At this point there should be no preload on any of the bearings and ring gear-to-pinion gear backlash should be just enough so that pinion and differential can be rotated easily and smoothly. Adjust ring gear and pinion bearings and ring gear-to-pinion backlash (see below). After these adjustments, proceed as follows:
5) Engage speedometer drive gear with gear on pinion shaft, then secure the assembly in carrier by tightening locking tab. Install differential carrier cover and a new gasket. Tighten cover bolts to 11-19 ft. lbs. Fill Carrier with 3 pints of recommended lubricant *(see "Lubrication" above).*

DIFFERENTIAL SIDE BEARING ADJUSTMENT: Lubricate bearings with axle lubricant, then tighten right side bearing adjusting sleeve while rocking differential assembly until there is no backlash between ring gear and pinion. Mark this point with a crayon, then back off adjusting sleeve three to four full notches to eliminate "O" ring wind-up. Retighten adjusting sleeve to one notch loose from the "zero backlash" crayon mark. Tighten left side bearing sleeve while moving differential laterally until all lash is eliminated. *NOTE - This point is determined when right side bearing rollers begin to turn when contact is made.* Mark both the adjusting sleeve and carrier with a crayon, then back off sleeve three or four full notches to release any "O" ring wind up, then tighten adjusting sleeve until **marks realign plus a minimum of two additional notches and a maximum of three additional notches** to align sleeve notches for locking tab installation, then install tabs.

PINION BEARING PRELOAD ADJUSTMENT: Tighten pinion bearing adjusting sleeve with Tool J-972 until pinion bearings are in contact with their races, then tighten pinion sleeve two additional notches. Measure pinion turning torque with Tool J-8362 (adapter) and an inch-pound torque wrench. Turning torque should be 4-6 inch-pounds (used bearings), 9-11 inch-pounds (new bearings). If turning torque is not within the above limits, move adjusting sleeve one notch at a time to obtain correct turning torque. When correct, install adjusting sleeve locking tab.

RING GEAR BACKLASH ADJUSTMENT: Mount a dial indicator on differential carrier and position indicator tip against back side of a ring gear tooth. Move ring gear to one end of its lash range, zero the dial indicator, then measure total backlash which should be .003-.010" (.005-.008" preferred). To reduce backlash, move ring gear toward pinion. When changing position of ring gear, side bearing adjusting sleeves must be moved the same number of notches to maintain side bearing preload. *NOTE - Turning adjusting sleeve one notch changes backlash approximately .003". Adjustments of one-half notch (.0015") can be made by reversing the adjusting sleeve locking tabs.*

POWERFLITE (CHRYSLER, DE SOTO, DODGE, PLYMOUTH)

Chrysler, DeSoto, Dodge, Plymouth (1954-55)

►CHANGES, CAUTIONS, CORRECTIONS

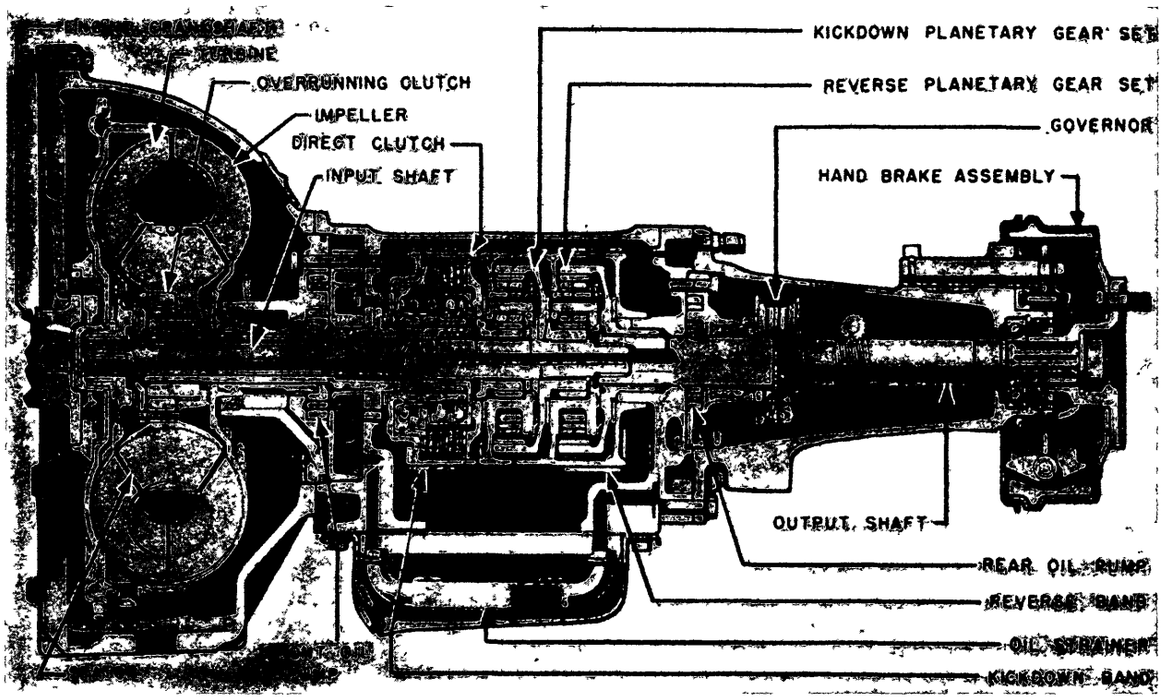
►*STARTING ENGINE BY PUSHING CAR:* Pushing recommended rather than towing. Turn ignition switch "on," place selector lever in "N." When car speed of approximately 25 MPH. reached, move selector lever to Low "L" position and car will crank engine.

►*TOWING POWERFLITE CARS:* Following procedure recommended:

Transmission Operating—Place selector lever in "N" and secure in this position by wiring lever in the gate on the lower end of the steering column. Tow car at moderate speeds. NOTE—For long distance towing (100 miles or over), propeller shaft should be removed.

Transmission Inoperative—Tow the car with rear end lifted or remove propeller shaft.

►*1954 THROTTLE CONTROL CHANGE NOTE:* Two types of throttle controls have been used and different throttle linkage adjustments are necessary. *See "Throttle Linkage Adjustment" below.*



►*1954 GOVERNOR PRODUCTION CHANGE:* A later type governor which provides a lower wide open throttle upshift and lower kickdown limit entered production approximately April 26, 1954. Shift patterns with the new governor are changed as indicated in "Transmission Shift Pattern" tables below. The later type governor can be installed on earlier cars and is available in replacement kits, Part No. 1450993 (6 Cyl. Cars), No. 1450994 (8 Cyl. Cars). *NOTE—Also see "1955 Governor Production Change"*

►*1954 DIRECT CLUTCH PRESSURE TESTING POINT PRODUCTION CHANGE:* a ⅛" take-off plug has been added to the bottom of the kickdown servo boss which can be used for checking direct clutch pressure. *See "Hydraulic Pressure Tests & Trouble Shooting" below.*

►*1954 SHUTTLE VALVE PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* A later type shuttle valve, Part No. 1643118 is used for production and can be used for service replacement. *CAUTION*—The adjustment screw is pre-set at the factory and MUST NOT BE CHANGED IN THE FIELD. *When replacing the older type valve with the later one, DO NOT install the old spacer and spring.*

►*1954 TRANSFER PLATE COVER PRODUCTION CHANGE:* A cast iron cover replaces the aluminum cover formerly used. This change was made to prevent possible warpage due to heat. The new cover plate, Part No. 1559108 can be installed on all previous transmissions.

►*1955 TORQUE CONVERTER OUTLET VALVE PRODUCTION CHANGE (To prevent loss of torque converter pressure under severe operating conditions):* A later type valve, Part No. 1630871 located in forward end of oil passage on left side of transmission case above line pressure take-off plug prevents loss of torque converter pressure. This valve can be installed on all early transmissions. *NOTE*—When installing the valve, make sure that the ball end of the valve is toward center of transmission. *Also see "Regulator Valve Body Production Change" below for later changes affecting the torque converter outlet valve.*

POWERFLITE TRANSMISSION SECTIONAL VIEW

►*1955 REGULATOR VALVE BODY PRODUCTION CHANGE (Converter pressure regulated at input, not at outlet):* The torque converter outlet valve has been eliminated by a change in the regulator valve body, the torque converter control valve and spring. The later type regulator valve body is identified by a letter "D" at end of the part number. The later Regulator Valve Package, Part No. 1643243 can be installed on early transmissions. *CAUTION*—The Torque Converter Outlet Valve must be removed to insure proper lubrication when the later type Regulator Valve is installed.

►*1955 INPUT SHAFT PRODUCTION CHANGE (To provide better sealing and bearing support):* A later type input shaft having a large area bushing (integral with shaft) replaced the former input shaft (three seal rings) at Transmission No. J-14-54 (stamped on lower right front corner of transmission case). The large area bushing is a press fit on the output shaft and is not serviced separately. When installing the later shaft in earlier transmissions, it will also be necessary to install a new reaction shaft.

►*1955 PLYMOUTH GOVERNOR PRODUCTION CHANGE (3-stage type replacing the 2-stage type):* A later type governor, Part No. 1653463 (V8 Cars), 1653464 (6 Cyl. Cars) provides a closer control of shift speeds The wide open throttle upshift limit is decreased and the low kickdown limit is increased (see "Transmission Shift Speeds" below). The later type governor can be used on earlier transmission for service replacement provided the complete package is installed. *NOTE*—Transmissions equipped with the new governor are identified by the letter "H" following the part number.

►*PLYMOUTH DIRECT CLUTCH DISC & PLATE REPLACEMENT CAUTION:* Six discs and six plates are included in Disc & Plate Package, Part No. 1450209 (for use on all PowerFlite Transmissions). On Plymouth 6 Cyl. & V8 Models, use only 5 discs & 5 plates. Installation of six of each part will not provide adequate clearance and may burn the discs and plates.

DESCRIPTION

DESCRIPTION: PowerFlite transmission consists of a torque converter and a two-speed hydraulically controlled planetary gear type automatic transmission. The entire transmission has a single independent oil system (front and rear pumps in transmission circulating oil through transmission, converter, and oil cooler with oil carried in transmission case oil pan). Hydraulic control consists of valve assemblies in the transmission and a hydraulic governor on the output shaft within the transmission extension housing which control the operation of the planetary gear sets (see OPERATION following). Torque converter is similar to unit used previously in "Fluid-Torque" Drive and operates independently.

Torque Converter: Provides a torque converter ratio of 2.6-1 for starting, acceleration, or heavy pulling whenever a torque gain is required. At cruising speeds above 45-50 MPH., the torque converter acts

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

as a fluid coupling with no torque multiplication.

Planetary Gears: Consist of a "Kick-down" (Low Range) planetary gear set providing a gear ratio of 1.72-1, and a Reverse planetary gear set providing a reverse drive with a gear ratio of 2.39-1. The actual effective gear ratio depends on selector lever position and car speeds as follows:

OPERATION

OPERATION: Transmission operation in each position of the selector lever is outlined below. In Drive "D" position (normal driving position), operation varies in accordance with the car speed and operating conditions. *See Shifting Speed tables below.*

Drive "D" Position: This is normal driving position.

Breakaway (Starting & Accelerating)—Transmission is down-shifted so that kick-down (low range) planetary gear set is in operation. The car starts and accelerates with both the torque converter providing a torque increase of 2.6-1 and the gears providing a torque increase of 1.72-1 for a total ratio of 4.47-1. At a car speed of 15-75 MPH. (depending on throttle position), the transmission automatically upshifts (locking out the planetary gears) so that all torque multiplication is provided by the torque converter. See Direct Drive.

Direct Drive—After the transmission upshifts, the only torque multiplication is provided by the torque converter (2.6-1) and this gradually diminishes as the car speed increases until at approximately 50 MPH. the ratio is 1-1 and the torque converter operates as a fluid coupling.

Kickdown (Forced Downshift)—At car speeds below 45-60 MPH., depressing accelerator pedal to the wide-open position will cause the transmission to downshift and drive through the kick-down planetary gear set. This provides the same torque multiplication as in "Breakaway" above. When the accelerator pedal is partially released, or when the car speed reaches 60-75 MPH., the transmission automatically upshifts (kick-down not operative above 60-75 MPH.).

Low "L" Position: Operation is the same as in Drive "Breakaway" above except that no upshift occurs and the planetary gear ratio of 1.72-1 remains in action regardless of the car speed.

Reserve "R" Position: This engages the reverse band (kick-down band and direct clutch disengaged) so that the engine drives through the torque converter and the reverse planetary gear set to provide a reverse drive with a torque multiplication of 2.6-1 (torque converter) and 2.39-1 (reverse planetary).

Neutral "N" Position: The transmission is completely disengaged (both bands and direct clutch disengaged) so that there is connection between the engine and the rear wheels. The Starter Neutral switch contacts are closed which permits the starter to operate to crank the engine.

LUBRICATION

Checking Fluid Level (Engine Hot)—With engine idling oil level should not be above the "full" mark on dipstick after car has been driven sufficiently to bring engine and transmission up to operating temperature. If oil is slightly below desired level, add a little oil at a time and recheck. *Do not add a full quart unless check indicates that it is required.*

Checking Fluid Level (Engine Cold)—Start engine, set hand brake and shift selector lever through all ranges. Allow engine to run approximately two minutes. Move selector lever to "N" (neutral) and check oil level with engine idling. Oil level should not be higher than ½" above the "low" mark on dipstick, and it should not be below the "low" mark on dipstick.

Draining & Refilling—Drain transmission case by removing drain plug from oil pan. Drain torque converter by removing drain plug from converter housing (remove access plate from bottom of flywheel housing, rotate torque converter until drain plug is down). Replace both drain plugs using new gaskets, if necessary, tighten oil pan plug to 20-25 ft. lbs. and torque converter plug to 45-50 ft. lbs. Install 5 qts. new fluid through transmission filler tube. Start engine and add approximately four quarts more while engine is running. Allow engine to idle for two minutes, then shift selector lever through all positions and return it to neutral. Add sufficient fluid to bring fluid level to "low" mark on dipstick (approx. 1 quart).

Recommended Fluid—Automatic Transmission Fluid Type A.

LINKAGE ADJUSTMENT

1954 CHRYSLER, DESOTO, DODGE

Gearshift Linkage: Place manual control lever at the transmission in "D" position which is the third detent from front of car (Chrysler & DeSoto); "N" position which is the second detent from rear of car (Dodge). Check angle of gearshift control bellcrank upper lever in relation to frame line. This should be 24-29° (Chrysler & DeSoto); 40-45° (Dodge) to the horizontal above the frame line and pointing slightly toward rear of car. If not at the correct angle, adjust as follows:

1) Disconnect front and rear gearshift control rods at gearshift control bell crank. Locate gearshift control bell crank as described above and adjust the rear gearshift control rod to the required length for a free fit in the bell crank lower lever, reinstall rod.

2) Place selector lever pointer in the "N" (neutral) position on the indicator dial at the top of steering column. Check clearance between the gearshift tube lever gate neutral stop land at bottom of steering column and the gearshift tube lever. This clearance should be .015" to .017" with .015" to .030" clearance between the gate and the wide flat face portion of the lever (see illustration), with gearshift tube in its normal fully returned position. To adjust, loosen the three attaching screws (on Chrysler & DeSoto), clamp (on Dodge) and move the gate to the desired position for correct clearance. Tighten attaching screws or clamp.

3) Make sure selector lever is in "D" position (Chrysler & DeSoto); "N" position (Dodge) and adjust the front gearshift rod to the desired length for a free fit to the upper lever of bellcrank. Reinstall rod.

4) Operate lever through all detent positions and check position of pointer on indicator dial.

►*CAUTION: If control does not operate properly or indicator does not indicate correctly, recheck the assembly and adjustment. DO NOT FORCE movement of selector lever.*

1954 PLYMOUTH

Gearshift Linkage: Measure distance between center of gearshift selector lever bearing bolt and gearshift rod bracket on steering column with a steel scale. Adjust to 49/64" (to get an accurate scale reading it may be necessary to force quadrant slightly away from rod bracket). Adjust as follows:

1) Remove steering column bracket assembly at selector lever and the bracket cap at the dash. Lower column enough to gain access to the cross head screw beneath selector lever. Remove lever, spring, and pointer.

2) Slide bracket assembly down on gearshift rod far enough to rotate and adjust bracket sleeve to 49/64" distance from center of hole to edge of bracket. This will provide approximately 3/16" minimum steering gear gearshift rod lever overlap on gate at lower end of steering column for "N" and "D" positions. Reinstall lever, spring, and pointer, then bracket assembly and bracket cap. Adjust gearshift rod lever stud to center of gearshift rod lever slot.

3) Raise car on hoist. Loosen the two nuts holding gearshift control rod to the swivel block attached to gearshift control bell crank mounted on transmission. Remove swivel block and control rod from bell crank. Move manual control lever on the transmission toward rear of car to place transmission in reverse gear, then move it one detent toward front of car which will place transmission in "N" (neutral). Reinstall swivel block in bell crank, leaving the control rod nuts still loose. Hold gearshift rod lever on steering column in "N" (neutral) position and draw up the front nut on the control rod to within 1/16" of the swivel block. Tighten nut to rear of swivel block, locking assembly in position.

4) Shift transmission through all gears and check for full engagement, making sure that the gearshift rod lever does not ride against control gate in any position. Readjust if necessary. Lower car and check position of selector lever pointer at "D" position. If necessary, bend pointer to locate it exactly at center of the letter.

1954 ALL MODELS

Throttle Linkage & Throttle Pressure: *CAUTION—Transmission throttle oil pressure must be checked and carefully adjusted when the throttl linkage is adjusted. This is important for proper peration.*

Chrysler, DeSoto & Dodge—

1) Check accelerator pedal released position. Included angle from face of pedal to floor at rear of pedal should be 118° (Chrysler & Dodge), 120° (DeSoto). Adjust length of accelerator bell crank to carburetor rod at carburetor throttle lever for correct pedal position.

Plymouth—

1) Measure distance between two anchor points of the throttle return spring. This distance should be 5⅝". To obtain the correct length, adjust throttle rod between carburetor lever and bell-crank.

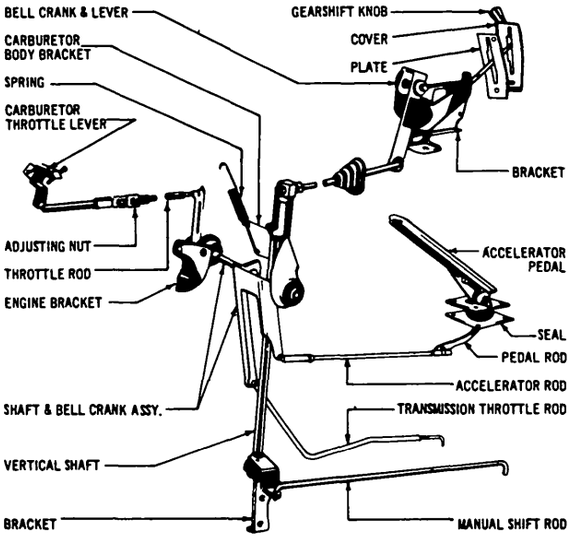
All Models—Proceed as follows:

2) Operate linkage through entire travel to make certain there is no bind in any position, see that carburetor throttle valves closed with accelerator in released position and that pedal has sufficient travel to fully open throttle valves and operate

CONTINUED N NEXT PAGE

POWERFLITE (C nt.)

kick down valve (opening of valve should be felt just as the wide open throttle position is reached).
3) Set engine idle at 475-500 RPM., with engine at normal operating temperature and with selector lever in "N" (neutral) position. ***CAUTION—Correct engine idle speed setting is very important when adjusting linkage and accurate tachometer should be used.***
4) With engine not running, remove Throttle Pressure Take-off Plug on right side of transmission case (⅛" pipe plug between reverse and kick down servos), connect 100 P.S.I. Pressure Gauge (Tool C-3292) at this point.
5) Start engine and place selector lever in "D" position ***(CAUTION—Set hand brake firmly).*** Disconnect the throttle linkage at transmission throttle control lever and operate the throttle valve several times by hand. Observe pressure reaction to lever movement to make sure throttle valve is not sticking.



►***THROTTLE CONTROL CHANGE NOTE:*** Two types of throttle controls have been used. The first type has no return spring on throttle lever and no positive stop for the throttle valve cam. The second type has a return spring located on transmission throttle lever and a positive stop for the throttle valve cam. These two types are not interchangeable and different adjustment procedures are required as follows:

6) Position throttle control lever so it is approximately 30° toward front of car from a right angle to the transmission center line (this procedure is not necessary on the second type control valve having the return spring, as the positive stop within the transmission positions control valve at the closed throttle position). Check throttle oil pressure which should be 13-15 P.S.I. If not within this range, adjust throttle pressure by removing throttle valve adjusting screw plug (on left side of transmission slightly forward and below Back-Up Light Switch). ***Approximately one quart of fluid will drain out when plug removed.*** Using Throttle Screw Adjusting Wrench C-3279, adjust throttle pressure to 14 P.S.I. Turn screw counter-clockwise to increase pressure and clockwise to decrease pressure. Replace plug and tighten to 20-25 ft. lbs.

7) Reconnect throttle linkage to throttle valve lever on transmission. To check throttle linkage adjustment pull slightly on accelerator pedal lever from below car. The throttle pressure should read 14 P.S.I. at idle speed and **rise 8 P.S.I. immediately** when accelerator depressed. If pressure rise not immediate with throttle opening, proceed as follows:

►**Cars With First Type Control Valve—**

8) Loosen lock screw on throttle control rod swivel, disconnect clip from throttle control rod and move swivel and throttle lever as far forward as possible. Next, slowly move throttle and swivel rearward until a slight resistance is felt. At this point, with very slight additional travel of lever toward rear, the throttle oil pressure should suddenly rise 8 P.S.I.
9) Holding swivel and throttle lever at exact position where the slight resistance noted, push slightly forward on the throttle rod to remove free play in connections, and while holding the rod and swivel in this position, connect swivel clip and tighten lock screw, securing swivel to correct position on

1955 POWERFLITE LINKAGE (TYPICAL)

throttle control rod. Recheck adjustment as in (7) above. Remove pressure gauge, replace throttle oil pressure take-off plug and torque to 10-12 ft. lbs.

►**Cars With Second Type Control Valve—**

8) Disconnect throttle control linkage at transmission throttle lever. Operate lever several times by hand. With control lever pointing toward front of car, move it rearward until a slight resistance is felt. Pressure at this point should suddenly rise 6 to 8 lbs. Return lever to a position approximately 1/16" toward front of car. With lever held in this position, install control rod, clamp and nut. Tighten nut just enough so rod can be moved through the clamp by tapping the lever slightly. Pull the accelerator pedal lever until engine speed just begins to indicate rise on tachometer. At this point tap transmission throttle lever into position which will allow the throttle pressure to rise from the 14 lb. mark. With slight additional throttle lever travel, the oil pressure should suddenly rise approximately 8 lbs. When pedal lever is released the throttle pressure should return to 14 lbs. Tighten the nut at point where the pressure starts to rise.

1955 CHRYSLER, DESOTO, DODGE

Gearshift Linkage Adjustment: Hold lever in gate (between neutral "N" and drive "D" positions) under tension (which is adjustable by a bracket to which it is attached behind instrument panel). With spring scale, tool C-394, pull out from selector lever knob. This should require 1-2 lbs., pull to break contact between selector lever and gate. If it does not, then adjust by loosening bracket attaching screws and sliding bracket to obtain the proper tension. Tighten screws and recheck tension ***(NOTE*** —If correct tension cannot be obtained by adjusting bracket, it can be corrected by removing the selector lever and mounting bracket assembly and bending the tension spring. Bend tension spring away from gate to ***decrease*** and toward to ***increase*** tension). Raise hood and inspect selector lever to torque shaft rod for interference where it goes through firewall. If necessary, bend rod to provide clearance at this point. Disconnect selector lever to torque shaft control rod at upper torque shaft rod (adjustment end). Make sure manual control lever located on side of transmission is in the neutral detent position (second detent from rear, all the way to rear and then one notch forward) by shifting it out of neutral and in again. With selector lever in neutral "N" position, push control rod toward firewall until instrument panel selector lever strikes the neutral stop land on gate. Adjust control rod swivel to a free fit in torque shaft upper lever. Clamp swivel in place with the two locknuts and check for free fit. Shift selector lever through all ranges ***CAUTION—The selector lever must go into gate without interference when shifting. Do not use force. Recheck assembly and adjustment.***

►***EARLY 1955 DESOTO THROTTLE LINKAGE ADJUSTMENT CAUTION:*** Approximately the first 2000 cars had a throttle control the same as the late 1954 models, and requires a different throttle linkage adjustment than later cars. The first type control can be identified by throttle Control Lever (on transmission) not having a positive stop at 30° forward movement of throttle lever. Adjust throttle linkage and throttle pressure on early cars in same manner as for late 1954 models. ***See "1954 Throttle Linkage Adjustment" above.***

Throttle Linkage & Throttle Pressure: ***CAUTION—Transmission throttle oil pressure must be checked and carefully adjusted when the throttle linkage is adjusted. This is important for proper operation.*** With engine at operating temperature, remove air cleaner and check choke valve for wide open position. Connect tachometer leads to coil and ground and adjust engine idle speed to 475-500 RPM, with selector lever in "N" (neutral). Stop engine. Loosen throttle linkage adjusting screw (located on accelerator-to-carburetor rod) and move rear portion of accelerator shaft shaft-to-carburetor rod rearward until it butts against stop. (Preload lightly.) With rods in line and rear portion of rod lightly preloaded, lock throttle linkage adjustment screw by tightening it to 10-15 ft. lbs. Start engine and recheck idle setting. With transmission in "N" (neutral) and hand brake set, raise car on hoist. Remove throttle oil pressure take-off plug (⅛" pipe plug) located between reverse and kick down servos on right side of transmission case. Connect 100 lbs., pressure gauge C-3292. Shift manual lever on left side of transmission case to "D" (drive) range and check throttle pressure which should be 13-15 lbs. (if necessary to readjust, set pressure to 14 lbs.). ***(NOTE—When manual control lever is moved into "D" range, the engine speed will drop approximately 50 RPM).*** If pressure is not within specifications remove throttle valve adjusting screw plug (⅜" pipe). ***(NOTE***—About one quart of transmission fluid will drain out). Insert adjusting screw wrench C-3279A or C-3279 and adjust throttle pressure to 14 lbs. Turn screw OUT to increase pressure and IN to decrease pressure. Open and release throttle several times to check for proper setting. Throttle pressure should return to 14 lbs. Replace throttle valve adjusting screw plug and tighten to 25 ft. lbs. With accelerator fully released and engine at 475-500 RPM, the pressure should read 14 lbs. Very slowly

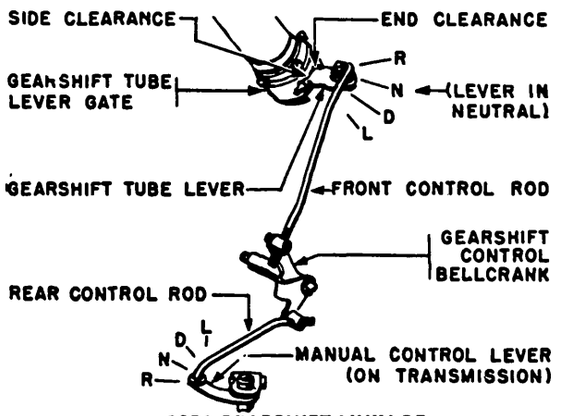
C NTINUED N NEXT PAGE

POWERFLITE (C nt.)

move the accelerator pedal or lever from underneath. With throttle and pressure properly adjusted, the throttle pressure should rise immediately with an increase in RPM *(NOTE—Do not use throttle rod when making this check)*. Remove oil pressure gauge and install pipe plug. Tighten to 12 ft. lbs. *(CAUTION—Replace any fluid that drained out during the adjustment)*.

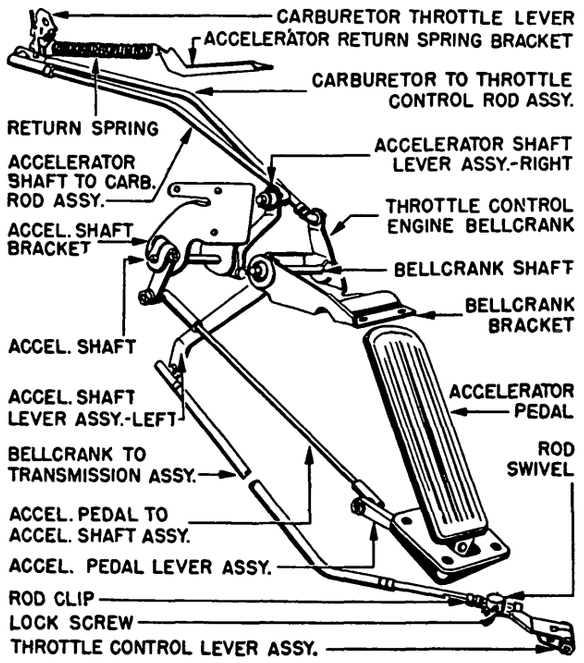
Checking & Adjusting Accelerator Pedal Height: At wide open throttle the tip of the pedal must be approximately ⅛" from the floor mat. To adjust, disconnect accelerator rod from bellcrank under the floor pan. Loosen locking nut and screw the connector counterclockwise on the shaft to raise pedal and clockwise to lower pedal. Reconnect rod to pedal bellcrank, lock with nut and turn down the connector nut.

1955 PLYMOUTH



Gearshift Linkage Adjustment: There should be 1/32" clearance between selector lever and the gate at instrument panel, with transmission in neutral. Adjustment is made at end of gearshift lever rod on engine side of firewall. Loosen adjusting nuts and place the transmission shift lever in neutral position. Tighten front adjusting nut to provide clearance on the instrument panel, then tighten rear nut. Check for full detent engagement at transmission.

Throttle Linkage & Pressure Adjustment: *(NOTE—To obtain correct relationship between throttle linkage and engine speed, throttle pressure as well as throttle linkage should be checked. Check linkage for possible binding and make sure lever returns to its stop)*. With selector lever in neutral "N" position, start engine and bring to normal operating temperature. Make sure carburetor is not on fast idle. Adjust engine idle speed to 475-500 RPM. in Neutral. Stop engine. Install tachometer leads for use under the car, start engine, then raise car on a hoist. Remove throttle oil pressure take-off plug (⅛" pipe plug) located between reverse and kickdown servos on right side of transmission. Connect the 100 lbs., pressure gauge C-3292. Move gearshift control lever on transmission one detent toward front of car to put transmission into "D" (drive) range. Disconnect throttle linkage at transmission throttle control lever and operate the throttle control lever several times by hand. Pressure should return to 13-15 lbs., with throttle lever returned to its stop. If it does not, adjust as follows: Remove the ⅜" pipe plug throttle valve adjusting screw plug on left side of transmission case (about one quart of fluid may drain out). Using throttle adjusting screw wrench C-3279A adjust the throttle pressure to 14 lbs. (Turn screw counterclockwise to increase pressure, clockwise to decrease). Shift transmission several times between "N" (neutral) and "D" (drive). Pressure should return to 14 lbs., when lever is returned to "D" (drive). Reinstall plug and tighten to 20-25 ft. lbs. *NOTE*—After throttle pressure is adjusted, adjust throttle control linkage:



V8 Engine Models—Loosen the clamp nut on throttle control rod (midway between carburetor throttle lever and cross shaft lever), and slide rear part of rod toward rear of car to take up all slack. Tighten clamp nut and make sure that carburetor is off fast idle.

6 Cyl. Engine Models—Loosen vertical clamp bolt at rear of engine and adjust the carburetor throttle lever rod to provide 5 7/16" distance between the anchor points of the throttle return spring. Then, with engine idling (off fast idle), take up slack at the vertical rod and tighten clamp nut.

On All Models—After adjustment is made, move gearshift control lever on transmission one detent toward rear of car to put transmission into "N" (neutral). Remove pressure gauge and reinstall plug. Tighten to 10-12 ft. lbs.

1954 GEARSHIFT LINKAGE

1954 THROTTLE LINKAGE

(CHRYSLER & DESOTO SHOWN—DODGE & PLYMOUTH SIMILAR)

BAND ADJUSTMENT

BAND ADJUSTMENT: *Kick-down (Front) Band can be adjusted externally, Reverse (Rear) Band adjustment requires removal of transmission case oil pan.*

Kick-down (Front) Band: *NOTE—Some models do not have band adjusting access hole in front floor pan (on left side of tunnel adjacent to accelerator pedal) and adjustment must be made differently from beneath car.*

Adjustment using Tool C-3291 (Cars with access hole in front floor). Remove accelerator pedal from hinged section of accelerator assembly, remove floor mat and access hole cover (on left side of tunnel immediately adjacent to accelerator pedal location). Then proceed as follows: Use Tool C-3291 (combination wrench and counter) to loosen adjusting screw locknut, check to see that adjusting screw is free in transmission case. Use **Inch-pound** reading torque wrench (Tool C-3380 or C-685) to tighten band adjusting screw to 60-72 In. Lbs. torque, then using counter on tool, **back off the adjusting nut exactly 3 turns,** hold the adjusting screw stationary and tighten the locknut securely.

Adjustment (cars without access hol in front floor)—Tool C-3291 cannot be used. Working from underneath car use a box wrench to loosen the band adjusting screw locknut (adjusting screw located on upper left side of transmission case in front of control lever assembly), back off locknut 4 turns (Chrysler & DeSoto), 9 turns (Dodge & Plymouth). Check to see that adjusting screw is free in transmission case. Use **Inch-Pound** reading torque wrench (Tool C-3380 or C-685) to tighten band adjusting screw to 60-72 In. Lbs. torque, mark adjusting screw position for reference and **back adjusting screw off exactly 3 turns,** hold adjusting screw stationary and tighten locknut securely.

Reverse (Rear) Band: Drain transmission case and remove oil pan. Remove locknut from reverse band adjusting screw (in reverse band lever at right rear within transmission case). Use Inch-Pound reading torque wrench (Tool C-3380 or C-685) to tighten adjusting screw to 20-25 In. Lbs. torque, then back **adjusting screw off 10 turns.** Install adjusting screw locknut, hold adjusting screw stationary and tighten locknut to 30-35 Ft. Lbs. Replace oil pan and refill transmission with fluid (see **LUBRICATION**).

ROAD TESTING TRANSMISSION: If transmission operation not satisfactory, following complete procedure is recommended to check performance and diagnose trouble:

FIRST—Make certain that engine properly tuned, idle speed correctly set at 475-500 RPM. with engine at normal operating temperature and selector lever in Neutral "N" position, and that transmission fluid level is correct. *CAUTION*—If throttle linkage disturbed in tuning engine, linkage must be adjusted before making following tests.

1) Move selector lever through all positions and check pointer with reference to gate and transmission detent positions. See LINKAGE ADJUSTMENT.

2) Start engine. Increase engine speed up to 800 RPM. checking for gear noise and dragging.

3) Move selector lever to "R" and check the shift for speed and smoothness. Back the car and check

C NTINUED N NEXT PAGE

POWERFLITE (C nt.)

for gear noise and dragging. ***CAUTION—do not use wide open throttle in Reverse.***

4) Make a Stall Test to check for band slippage (see STALL TEST below). If band slippage indicated, adjust bands before proceeding with the test (see BAND ADJUSTMENT).

NOTE—Refer to "Transmission Shifting Speed" data for correct upshift and downshift speeds when making the following tests:

5) Accelerate car with very light throttle. Note speed at which upshift occurs and check smoothness of the shift. Slow the car to approximately 15 MPH. and rapidly accelerate to wide-open throttle **without going into the kick-down position.** Check for clutch slippage. Transmission should not downshift.

6) With car operating 15-20 MPH., make a kick-down shift by opening throttle to kick-down position, then release accelerator to approximately the half-throttle position so that transmission upshifts. Check smoothness of each shift.

7) With car operating at 35-40 MPH., make a kick-down shift by opening throttle to kick-down position, then release accelerator to closed-throttle position. Check smoothness of each shift.

8) With car operating at 45 MPH., make a kick-down shift by opening throttle to kick-down position, then accelerate car with transmission kicked down until transmission upshifts. Check this shift speed and smoothness of both shifts.

9) Slow car speed to 65 MPH. (Chrysler & DeSoto), 50 MPH. (Dodge & Plymouth) and attempt to make a kick-down shift at this speed. Transmission should not downshift (this speed is above kick-down limit).

10) Slow car to 40-50 MPH., move selector lever to "L." Transmission should downshift. Check for gear noise.

11) Increase car speed to approximately 20 MPH. and move selector lever to "D." Transmission should upshift. Coast car to a stop and check speed at which transmission downshifts. Check smoothness of shift.

TESTING

TRANSMISSION SHIFT SPEEDS

②—With early type 2-stage governor. See *Production Change* above.
③—With later type 3-stage governor. See *Production Change* above.

STALL TEST: Use an accurate tachometer to check the engine speed. With engine idling, move selector lever to "D" and note smoothness and speed of the shift. Set hand brake firmly and apply foot brakes to hold car, accelerate engine to wide-open throttle and check engine speed. Speed in excess of maximum RPM as indicated below may be caused by band slippage. See "Band Adjustment."

1954 Stall Performance ①

Car Model	②Engine RPM
Plymouth, Dodge 6, DeSoto 8	1275-1375
Dodge 8	1400-1500
Chrysler C-63-2 & C-64	1400-1500
Chrysler C-63-1	1450-1550
Chrysler 6	1200-1300
DeSoto 6	1150-1250

1955 Stall Performance ①

Car Model	②Engine RPM
Chrysler C-67	1380
Chrysler C-68, C-69, C-70, C-300	1540
DeSoto S-21	1585
DeSoto S-22	1490
Dodge 6 Cyl	1330
Dodge Royal	1450
Dodge Custom Royal	1465
Plymouth 6 Cyl	1330
Plymouth 157 HP V8	1395
Plymouth 167 HP V8	1435

①—Wide open throttle, selector lever in "D" range, at sea level
②—Plus or minus 50 RPM

►***CAUTION—When making stall test do not hold throttle wide-open for more than a few seconds. If engine speed excessive and is not corrected by band adjustment, make additional checks as listed below.***

If excessive engine speed not due to incorrect band adjustment, check for: incorrect Gearshift Linkage or Throttle Linkage Adjustment; leakage at Valve Body mating surfaces; defective Throttle Valve, Shuttle Valve, or Valve Body End Cover Plug; defective Kick-down Servo parts (piston, guide, band, lever, strut, etc.).

CONTINUED N NEXT PA E

POWERFLITE (C nt.)

HYDRAULIC PRESSURE TESTS & TROUBLE SHOOTING: *CAUTION—Pressure difference from 15 lbs. to 250 lbs., will be found in making following tests and correct pressure gauge must be used.*

C-3292 (100 P.S.I.) Gauge—Use for Throttle Pressure, Governor Pressure and Lubrication Pressure checks.

C-3293 (300 P.S.I.) Gauge—Use for Line Pressure check.

Line Pressure: Remove ⅛" pipe plug from line pressure take-off hole (front left side of transmission case), install C-3293 (300 P.S.I.) pressure gauge at this point. Check Reverse oil pressure first (brakes off), then apply brakes to hold car and check the other points. Run engine at speed indicated in table below, check line pressure for each selector lever position as indicated.

Line Pressure

Gearshift Position	Engine RPM.	Pressure (P.S.I.)
R	1600	225-275
N	800	85-95
D	800	85-95
L	800	85-95

If line pressure not correct, check for: Low oil level or clogged oil strainer; defective Regulator Valve and Spring, Manual Valve and Lever, Throttle Valve, Cam, and Spring; Oil Leakage at Valve Body or Regulator Body mating surfaces; defective Kickdown Piston and related parts; defective Reverse Piston and related parts; Worn Front Pump or defective pump drive sleeve or pinion.

Direct Clutch Pressure: *(NOTE—Check line pressure before checking direct clutch pressure as any deviation in line pressure will affect direct clutch pressure).* Remove ⅛" pipe plug from direct clutch pressure take-off hole located at bottom of kickdown servo boss on right side of transmission (directly above filler tube connection on side of transmission). Connect a 300 lb. pressure gauge at this point. With rear wheels raised and free to turn, accelerate engine slowly until an upshift occurs. During the upshift, the pressure should rise rapidly from 0 to 90 lbs. pressure in 1½-2 seconds. With an engine speed of not less than 650 RPM, and transmission upshifted, the direct clutch pressure should read within 10 lbs. of line pressure. ***If direct clutch pressure not correct,*** refer to "Shift Quality" and "Excessive Engine Speed on Upshifts" in "Trouble Shooting & Diagnosis" below.

Throttle Pressure: Remove ⅛" pipe plug from throttle pressure take-off hole (right center of transmission case between the servos), install C-3292 (100 P.S.I.) gauge at this point. Apply brakes to hold car, place selector lever in "D" position, run engine at speed indicated in table below and note throttle pressure at each speed.

Throttle Pressure

Throttle Opening	Engine RPM.	Pressure (P.S.I.)
Closed	Idle	13-15
Wide-open	Stall	80-90

►***CAUTION—When making above test do not hold throttle wide-open for more than a few seconds. If engine speed exceeds 1500 RPM. (indicating band slippage), refer to STALL TEST above for recommended checks.***

If throttle pressure not correct, check Line Pressure (above), and also check for: incorrect Throttle Linkage adjustment; leakage at Valve Body mating surfaces; defective Throttle Valve, Cam, and Spring; defective Throttle Pressure Check Ball or Kick-down Valve Ball and Rod; defective kickdown piston or related parts.

Governor Pressure: Remove ⅛" pipe plug from governor pressure take-off hole on lower left side of output shaft support (plate between transmission case and extension housing), install C-3292 (100 P.S.I.) gauge at this point. Support car securely with rear wheels off the floor so that they are free to turn, place selector lever in "D" position, run engine at car speed indicated (as noted on speedometer), note governor pressure in each speed range.

Governor Pressure

1954 Chrysler

1955 Plymouth 8

Car Speed (MPH)	Pressure P.S.I.
13-16	15
23-26	45
55-62	60

If governor pressure not correct, check for: leakage at Valve Body mating surfaces or Output Shaft Support gaskets, defective Governor assembly, defective Rear Pump.

Lubrication Pressure: Check only when there is reason to suspect that it is incorrect. Connect gauge in oil cooler return line as follows: Disconnect cooler return line from flared tube connector fitting at upper left side of output shaft support (between transmission case and extension housing), install a ⅛" short pipe nipple and ⅛" pipe tee at this point, connect the flared tube connector fitting which was removed from the transmission into the tee, connect C-3292 (100 P.S.I.) gauge to the other side of the tee, connect oil cooler return line to the flared tube fitting *(CAUTION*—always place a flared tube nut in the flared tube fitting when screwing it in or out to prevent crushing the fitting). Run the engine at 800 RPM. with selector lever in "N" and note lubrication pressure which should be 10-20 P.S.I.

If lubrication pressure is not correct, **check for: leakage at Regulator Body mating surfaces or at Output Shaft Support gaskets; defective Converter Control Valve; defective Front Pump Drive Sleeve; defective Reaction Shaft seals or worn reaction shaft bore; defective Input Shaft seal rings; plugged lubrication holes.**

TROUBLE SHOOTING & DIAGNOSIS

EXCESSIVE SLIPPAGE:

All Ranges—Inspect oil level. Adjust gearshift linkage. Check oil pressure; if low, inspect regulator valve and torque converter control valve for sticking. Inspect valve body in transmission case mating surfaces for evidence of oil leakage.

Kickdown—Readjust throttle linkage and kickdown band. Inspect valve body to transmission case mating surfaces for evidence of oil leakage. Check operation of throttle valve and note wear of valve bore and cam. Check spring. Check valve body end cover for oil leakage. Check shuttle valve for free movement. Inspect kickdown piston and guide for binding. Inspect spring. Inspect band lining for wear and band lever for free movement.

Kickdown (Over 25 MPH)—Inspect valve body end cover for oil leakage. Inspect shuttle valve and plug for free movement. Inspect spring.

Direct—Inspect valve body to transmission case mating surfaces for evidence of oil pressure leakage. Check kickdown piston for binding. Check shaft seal rings and clutch retainer bushing for wear. Check clutch discs, piston and clutch check valve.

Reverse—Check reverse band adjustment. Inspect transmission case to valve body mating surfaces for evidence of oil pressure leakage. Inspect

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

reverse servo assembly for wear or binding Inspect reverse lever and linkage for free movement

Hill Climbing—Insufficient oil will result in low pressures to kickdown servo or direct clutch if oil level is low

SHIFT PATTERN:

No Upshift—Check oil level and gearshift linkage adjustment Check governor and throttle pressure If there is no pressure rise when accelerating engine in direct drive, governor valve may be stuck closed Check valve body to transmission case for parallelism Check manual valve and lever for correct detent engagement Check shift valve for free operation and shift valve spring for breakage Check kickdown piston assembly Check rear pump drive pinion Drive pinion ball may be cracked or broken, permitting pinion gear to slip Inspect clutch ball check for proper operation Ball check valve must operate freely and seat properly

No Shift in "D" (Drive) Range and an Upshift In Low Range—The cause is the governor valve sticking open This can be verified by checking governor pressure (see "Governor Pressure Test" above) If governor pressure exceeds the pressures indicated in table governor valve is possibly stuck and in most cases can be corrected in the following manner Clean off area around governor pressure take-off plug and remove plug Cover oil filler tube with a cloth or plug and hold firmly to prevent air from forcing transmission oil out through filler tube Screw a piece of 1/8" pipe into hole to help direct air into unit Apply clean filtered air to pipe in short blasts, tapping parking brake drum at same time with a rubber hammer just enough to jar governor After applying air pressure, recheck governor pressure and see if valve has been freed up In cases where governor pressure is still to high, it will be necessary to remove transmission extension case for further inspection

Low Upshift Pattern—Readjust throttle linkage Check governor pressure Governor valve may be binding or sticking Inspect the rear pump assembly Check valve body to transmission case for parallelism Check operation of throttle valve and inspect cam and spring Check shift valve for free operation and spring for breakage

Low Upshift Pattern at Heavy Throttle—Inspect regulator valve, throttle valve, and governor for burrs or dirt which may cause binding or sticking Inspect the regulator spring

High Upshift Pattern—Readjust throttle linkage and check both throttle and governor pressures Adjust throttle pressure if necessary If throttle pressure does not rise according to speeds on chart (see "Throttle Pressure" above), throttle valve may be sticking Inspect for dirt or burrs Inspect throttle cam for wear Check valve body to transmission case for parallelism Check shift valve spring If governor pressure does not correspond to pressures indicated in "Governor Pressure" table above, remove governor and inspect valve for sticking Check rear pump gears for wear, broken teeth or excessive clearance Inspect pump drive pinion ball

All Upshifts Below 14 MPH—Inspect throttle valve, cam and spring Check throttle pressure check ball Check governor valve for sticking

Erratic Shifting—Check oil level Inspect valve body to transmission case for parallelism Check action of shift valve Inspect governor support gaskets for oil leakage

No Downshift—Check governor pressure High initial pressure indicates valve is stuck open Remove governor and inspect Inspect shift valve action, check spring

Low Downshift Speed—Governor valve is stuck open Remove and clean and check for burrs and dirt

High Downshift Speed—Readjust gearshift linkage Inspect valve body to transmission case for parallelism Inspect manual valve and lever Inspect kickdown valve and ball

No Kickdown—Adjust throttle linkage Inspect valve body to transmission case for parallelism Inspect throttle valve, cam and spring Also inspect kickdown valve and shift valve components

Low Kickdown Limit—Check governor pressure Governor valve may be sticking due to dirt Inspect regulator valve and spring for proper operation Inspect rear pump gears and drive pinion ball Check valve body cover plate for parallelism

SHIFT QUALITY:

Harsh Shift from Neutral to Reverse—Adjust engine idle speed Readjust rear band Inspect condition of the reverse band, strut and linkage Inspect the reverse servo piston, spring valve and rings

Harsh Shift from Neutral to Drive—Adjust engine idle speed Adjust throttle linkage Inspect kickdown servo pistons, springs, guide, rod and piston rings

Delayed Shift from Neutral to Drive—Adjust kickdown band Inspect condition of band, strut, lever and lever shaft

Excessive Engine Speed Increase on Upshifts—Check oil level and adjust throttle linkage Inspect regulator valve and spring and check operation of valve in regulator body Check valve body mating surface for parallelism Inspect throttle valve, cam and spring Check operation of valve in valve body Inspect kickdown piston components Check mating surfaces of regulator valve body and transmission for parallelism Inspect reaction shaft seal ring for deterioration Inspect input shaft oil seal rings for wear or breakage and condition of reaction shaft bore Inspect clutch retainer bronze bushing If worn below bronze surface, replace retainer Inspect condition of reaction shaft oil seal rings for wear or broken ends Inspect condition of clutch plate and condition of friction material on seal ring Check clutch check valve ball

Excessive Engine Speed Increase on Upshifts at Light Throttle—Check line pressure Inspect front oil pump gears for wear and excessive clearance

Harsh Upshift—Adjust throttle linkage Inspect regulator valve and spring Check for sticking shuttle valve Check valve body mating surfaces for parallelism Inspect throttle valve, cam and spring Inspect kickdown piston components Check regulator valve body mating surfaces for parallelism Inspect direct clutch spring, spring retainer, and snap ring

Harsh Lift Foot Shift—Adjust throttle linkage Check valve body mating surface Check operation of throttle valve Inspect valve, valve bore, cam and spring Inspect servo pressure bleed valve for dirt Check operation of shuttle valve Inspect shuttle valve, plug, inner and outer springs, and guide pin

Excessive Engine Speed Increase on Downshift at Part Throttle—Check oil level and adjust throttle and gearshift linkage Check valve body mating surface Check operation of manual valve and valve lever Inspect servo restrictor valve and operating plug Check plug for free operation Check valve spring for distortion or looseness

Harsh Downshift—Adjust engine idle speed and throttle linkage Inspect valve body mating surface Inspect throttle valve, cam and spring for proper operation Inspect for dirt, burrs or wear, or breakage Inspect servo restrictor valve for proper operation Inspect clutch plates and disc friction material Inspect the piston for wear or scoring Check seal for wear or deterioration which would result in leakage Inspect thrust washers for excessive wear

Excessive Increase in Engine Speed on Kickdown—Readjust kickdown band Check regulator valve and spring for proper operation Inspect for dirt wear, or breakage Check valve body mating surface for nicks, burrs and trueness, which would cause leakage Check operation of servo restrictor valve and shuttle valve Inspect valve and plug for dirt, burrs or wear Inspect all parts of kickdown piston assembly Inspect piston rings for excessive wear or broken ends Check governor valve for wear, dirt binding or sticking Inspect rear pump gears for excessive wear or broken teeth Check pump clearance, drive pinion gear and pinion ball

Harsh Kickdown—Adjust kickdown band Inspect regulator valve and spring Inspect for dirt, burrs or breakage Inspect servo pressure bleed valve for dirt Check operation of shuttle valve Check valve and plug for burrs, dirt or excessive wear Inspect all parts of kickdown piston assembly Inspect piston rings for scoring, wear or broken ends Inspect regulator valve body mating surface for nicks, burrs and trueness which would cause leakage Inspect reaction shaft neoprene seal for deterioration Inspect governor valve for free operation Check for dirt which would cause sticking Inspect rear pump gears for excessive clearance, worn or chipped teeth Inspect drive pinion gear and drive pinion ball Inspect the input shaft seal rings for excessive wear or broken ends, and reaction shaft bore for scoring Inspect all parts of the direct clutch assembly

OIL PRESSURE:

No Governor Pressure—Governor valve may be stuck in closed position due to dirt To free valve, apply a short spurt of high air pressure (90 lbs) to governor pressure take-off hole and at same time tap transmission extension housing with a rubber mallet Before applying air pressure, cover filler tube with a cloth In addition, drain two or three quarts of oil from transmission oil pan After air is applied, reinstall governor pressure take-off plug and run transmission in Reverse a few seconds Recheck governor pressure This corrective procedure may not be permanent If valve becomes stuck again, remove governor for servicing If pressures do not correspond to those indicated in "Governor Pressure" table above, the governor may need service However, before servicing governor, check the other points in the transmission that could

C NTINUED ON NEXT PA E

POWERFLITE (C nt.)

cause low pressure as follows: Check the valve body mating surface for trueness, nicks or burrs. These could cause oil leakage. Check both output shaft support gaskets for evidence of internal leakage. Check operation of governor valve and inspect for foreign matter. Check the rear pump gears for broken teeth, wear, and excessive clearance. Check the mating surface of output shaft for trueness burrs or nicks.

High Initial Governor Pressure—High governor pressure at low engine speeds is due to the governor valve being stuck in the open position, usually caused by dirt *(see "No Governor Pressure" above)*, for clearing with air pressure.

Line Pressure—If line pressure does not correspond to pressures indicated in "Line Pressure" table above, it will be necessary to investigate and make the following adjustments or corrections: Check transmission oil level. Inspect regulator valve for free operation, dirt or burrs, and condition of valve spring. Check valve body mating surface for trueness, nicks or burrs. Check operation of manual valve and lever. Inspect front pump gears for worn or chipped gears. Check clearance between gears and face of housing.

Throttle Pressure—If throttle pressures do not correspond to pressures indicated in "Throttle Pressure" table above, check line pressure and make the following adjustments and corrections: Adjust throttle linkage. Inspect operation and condition of regulator valve and spring. Check valve body mating surfaces for nicks, burrs and trueness. Check operation and condition of throttle valve, cam and spring. Check throttle pressure check valve ball for nicks and dirt. Inspect condition of kickdown rod and ball.

Direct Clutch Pressure—Direct clutch pressure should be approximately 10 lbs. lower than line pressure with transmission upshifted and engine speed not lower than 650 RPM. If not, refer to "Excessive Engine Speed on Upshifts" above. A pressure drop between line pressure and direct clutch pressure as high as 25 lbs. may be due to broken or damaged seal rings in the direct clutch circuit. These are: three interlocking type input shaft seal rings; the direct clutch piston retainer seal ring, direct clutch piston neoprene seal ring, the neoprene reaction shaft seal ring, and the two interlocking type reaction shaft seal rings.

Lubrication Pressure—Lubrication pressure is checked at the upper left side of the output shaft support, Remove the ⅛" pipe plug and use 100 lbs., pressure gauge C-3292 to check pressure. Lubrication pressure should be 35 to 50 lbs. pressure with transmission in neutral and engine speed at fast idle. If pressure readings are incorrect, check line pressure and inspect torque converter control valve. Low pressures may be due to internal oil leakage at the following points: drive sleeve seal ring, regulator valve body mating surface, reaction shaft seal ring, output shaft support gaskets, input shaft seal rings, and reaction shaft bore. Low oil pressure may also be caused by plugged lubrication lines.

IMPROPER RESPONSE TO GEARSHIFT SELECTOR LEVER POSITIONS:

Moves Forward in "N" (Neutral)—Adjust gearshift linkage. Adjust kickdown band. Inspect manual valve lever assembly. Check valve body mating surface for nicks, burrs and trueness which would cause leakage. Check operation of manual valve. Inspect all parts of kickdown piston. Check regulator body mating surface for nicks, burrs and trueness. Check clutch discs and plates for warpage which would cause dragging. Inspect clutch ball check.

Car Moves Forward in "N" (Neutral) at High Engine Speed—Clutch check valve ball bleed hole may be plugged causing centrifugal oil pressure to partially engage the direct clutch. A slight surge which is not continuous is normal.

Car Moves Backward in "N" (Neutral)—Readjust gearshift linkage and inspect manual valve and valve lever for proper engagement. Adjust reverse band, levers, strut, and shaft. Check for binding, dirt, excessive wear.

MISCELLANEOUS DIAGNOSIS PROCEDURES:

Starter Will Not Energize—Adjust gearshift linkage. Test neutral starter switch. Inspect manual valve lever for proper engagement.

Hard Shifting Into "N" (Neutral)—Check operation of neutral starter switch and inspect manual valve lever.

Hard Shifting Into "R" (Reverse)—Check operation of backup light switch and manual valve lever.

Oil Foams From Filler Tube—Check fluid level in transmission. Inspect transmission breather vent.

PARTS REMOVAL & INSTALLATION (TRANSMISSION IN CAR)

►***NOTE: Transmission must be removed from vehicle for the removal and replacement of parts other than those listed below.***

Oil Pan: Remove oil pan filler tube, drain transmission and remove oil pan attaching screws and oil pan. When installing pan, tighten screws evenly and torque to 12-17 ft. lbs.

Governor Servicing: ***NOTE—It is necessary to remove transmission extension to remove governor assembly. See "Transmission Overhaul" below for Extension Housing Removal, Governor Removal, Overhaul & Installation.***

Valve Body & Transfer Plate Assembly (Removal): Remove oil pan and disconnect throttle and manual control lever linkage from levers. Loosen throttle and manual control lever assembly locking screws. Slide throttle valve operating lever assembly off shaft and remove throttle valve camshaft felt retainer and felt. Slide manual valve lever assembly off shaft and remove valve lever shaft seal cover. Remove the two oil strainer support screws and washers and take the strainer assembly off valve body and plate assembly. Remove transfer plate screws and lock washers and remove valve body and transfer plate assembly. For overhaul. *See "Valve Body Overhaul" below.*

Installation—Clean mating surfaces and check for burrs on both transmission case and valve body transfer plate. Place valve body and transfer plate assembly into position and install plate screws and lockwashers *(CAUTION—The two 1⅝" screws go through transfer plat cover on valve body. The three 1⅛" ar used in the other holes)*. Tighten evenly to 12-17 ft. lbs. torque. Make sure the two oil strainer tube seals are in position over oil strainer and place oil strainer assembly into position on transfer plate. *(CAUTION—Check to see that oil tubes on strainer properly enter valve body)*. Install the two oil strainer support screws and torque to 12-17 ft. lbs. Place manual lever shaft seal cover over manual valve lever shaft and slide into position on transmission case. Install manual lever (arm side of lever against cover) on manual valve lever shaft, and tighten locking screw. Place throttle valve camshaft felt and retainer over throttle valve shaft. Install throttle valve lever assembly on throttle camshaft and tighten locking screw. Check operation of control by shifting into all positions. Check kickdown operation and manual lever contact on neutral safety and back-up light switches. Install oil pan and adjust throttle linkage and gearshift linkage.

Manual Control Valve Lever Shaft Oil Seal Removal & Installation: Remove oil pan, valve body and transfer plate assembly. Using a suitable brass drift, drive seal out of transmission case from below. To install, use tool C-3277. Start seal squarely into bore and tighten tool C-3277 until it is flush with the case. This properly positions seal. Install valve body and plate assembly and oil pan.

Kickdown Piston (Removal): Remove oil pan, valve body and transfer plate assembly. Loosen kickdown band adjusting screw locknut and back adjusting screw out sufficiently to permit kickdown band strut to be removed by compressing band ends. With kickdown band lever hanging down, install tool C-3289 on transmission case. Apply sufficient pressure on kickdown rod guide to permit easy removal of the snap ring. Loosen compressing portion of tool and remove piston rod guide, piston spring and kickdown piston rod assembly (the kickdown piston cushion spring will fall out of piston when rod assembly is removed). Using snap ring pliers, inserted inside of kickdown piston, remove piston from transmission case. *See "Overhaul" below, for disassembly and inspection.*

Installation—Make sure the two interlocking seals are locked in position and all seals are coated with Lubriplate, then place kickdown piston into transmission case. With one hand apply pressure to piston and at the same time carefully compress bottom seal and push piston into case. *(CAUTION—*After bottom seal has entered, piston will seem to hang at two different locations while being pushed into case. This is due to seals entering cylinder, do not use extreme force. If any rings should be broken when piston assembly is being installed, transmission will not operate properly.) Slide piston spring over kickdown piston rod assembly then balance piston cushion spring on rod assembly (Lubriplate may be used to help hold cushion spring in position on rod assembly), and install in piston. Holding it in this position, install kickdown piston rod guide assembly on piston rod assembly. Using tool C-3289, and extreme care, compress the kickdown piston spring to the point that piston guide seal slightly binds on transmission case. Work seal into position and gradually compress spring until seal enters case and snap ring can be installed. Install kickdown piston rod guide snap ring, making sure it is properly seated. Loosen compression portion of tool and remove tool from transmission case.

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

With one end of band fit over adjusting screw, compress the other end sufficiently to install the kickdown band strut between kickdown band and band lever *(CAUTION*—Make sure band strut slot engages with kickdown band strut pin in band end). Install valve body, plate assembly and oil pan. Adjust kickdown band.

Reverse Servo (Removal): Remove oil pan, valve body and transfer plate assembly. Loosen reverse servo adjusting screw locknut and back adjusting screw out sufficiently to permit reverse band strut to be removed by compressing band ends. Remove reverse servo piston sleeve. Mount tool C-3289 on transmission case and compress reverse piston spring retainer. Using a screwdriver, remove the reverse servo piston and valve assembly spring retainer snap ring and loosen compressing part of tool (Spring retainer may require guiding out of transmission case). Remove spring retainer, spring, reverse servo piston and valve assembly from transmission case. Using C-3229 pliers, remove the reverse servo piston valve spring snap ring, and remove spring and valve from piston. *See "Overhaul" below, for disassembly and inspection.*

Installation—Place reverse servo piston valve and spring in reverse servo piston (shaft on valve protruding through hole in bottom of piston). Using snap ring pliers C-3229, install reverse servo piston valve spring snap ring, making sure it is properly seated. Coat reverse servo piston ring (neoprene) with Lubriplate. Insert reverse servo piston and valve assembly into transmission case in a cocked position, then by rotating piston, the ring will enter case without being damaged. Place reverse servo piston spring over piston and position spring retainer over spring. Using tool C-3289, compress spring sufficiently to install snap ring. Make sure retainer is correctly installed, and snap ring seated. Remove tool C-3289 from transmission case and install reverse servo piston sleeve. Make sure piston sleeve slides freely on piston by working it up and down. Hook one end of reverse band assembly in reverse link assembly, compress other end sufficiently to install reverse strut in slots of reverse band assembly and reverse band lever assembly. Adjust reverse band. Install valve body, transfer plate and oil pan.

Speedometer Pinion (Removal & Installation): Disconnect speedometer cable and housing from sleeve assembly on transmission, and remove speedometer pinion and sleeve. When installing sleeve and pinion assembly, torque it to 40-45 ft. lbs.

Neutral Safety and Back-Up Light Switch Removal & Installation Note: It is not necessary to drain transmission to remove these switches. A small amount of lubricant will drain from transmission when these switches are removed. When installing, tighten switches to 15-20 ft. lbs.

Transmission Output Shaft Rear Bearing Oil Seal (Removal): Disconnect the front universal joint and secure shaft to frame out of the way. Apply hand brake and remove propeller shaft flange nut and washers. Release hand brake and install puller C-452. Remove propeller shaft flange and drum assembly. Remove transmission support grease shield spring (small one). Remove brake support grease shield from extension housing *(CAUTION—If screwdriver or sharp instrument used to remove shield, do not damage the neoprene sealing surface at bottom of shield).* Install puller C-748 and remove rear bearing oil seal.

Installation—Install rear bearing oil seal with tool C-3205. Install brake support grease shield on extension housing *(CAUTION—Indent on grease shield must match groove in housing for correct positioning. Install grease shield far enough on housing to permit installation of spring).* Install brake support grease shield spring with opening in spring toward adjusting sleeve. Make sure spring is properly seated in groove. Make sure brake adjustment is backed off and install drum assembly (In some instances it may be necessary to use tool C-496 to press drum assembly on output shaft). Install propeller shaft flange washer, shakeproof washer and nut. Adjust hand brake. Apply hand brake and torque propeller shaft flange nut to 140-160 ft. lbs. Connect front universal joint.

Transmission Regulator Valve Assembly (Removal): Remove transmission regulator valve spring retainer, gasket, and spring. Using a mechanical retriever or a piece of welding rod inserted in end of valve, remove valve.

Installation—Place valve in position in valve body. Install regulator valve spring, gasket, and retainer and tighten to 45-50 ft. lbs. torque.

Torque Converter Control Valve Assembly (Removal): Remove control valve spring retainer, gasket, and spring. Using a mechanical retriever or a piece of welding rod inserted in end of valve, remove valve.

Installation—Reverse removal procedure.

Oil Cooler (Removal): Drain radiator, remove battery and battery pan. Remove lower radiator-to-cooler hose. Remove inlet and outlet oil tubes. Remove oil cooler to water pump flange bolts.

Installation—Clean mating flanges thoroughly and install new flange gasket. Install cooler to water pump and tighten flange bolts. Install inlet and outlet oil tubes. Install lower radiator-to-cooler water hose. Install battery and battery pan. Refill radiator and start engine. Check carefully for water and oil leaks.

TRANSMISSION REMOVAL

1) Disconnect battery and raise car off floor. Drain transmission and torque converter. When fluid has drained, replace drain plug. Disconnect oil pan filler tube from oil pan. Disconnect front universal joint and secure shaft to frame out of the way.

2) Remove adjusting screw cover plate and cable clamp bolt from hand brake support. Disconnect speedometer cable from transmission extension. Disengage ball end of cable from hand brake operating lever and remove cable from brake support.

3) Disconnect neutral safety and back-up light switch wires at switches and unclip wires from crossmember. Disconnect manual and throttle control linkage from levers. If car equipped with oil cooler, disconnect cooler lines from transmission case and remove bracket holding lines to cylinder block. On all models remove screws holding exhaust pipe bracket to transmission case.

4) Remove bracket holding oil cooler lines to cylinder block. Remove nuts and lockwashers holding engine rear support insulator to cross-member, leaving insulator attached to transmission.

5) Install engine support fixture tool C-3245, insert hooks of fixture firmly into holes in side of frame member with support ends up; against the underside of oil pan flange. Adjust fixture to support weight of engine. Raise engine slightly, remove cross-member to frame bolts and remove crossmember.

►*CAUTION—When using tool C-3245, do not lower engine more than three inches from floor boards to avoid disrupting the set position of water hoses and other engine attachments.*

6) Remove the two upper transmission-to-adapter screws and lockwashers and install guide studs C-3276. Remove the lower screws and slide transmission straight back to avoid damage to converter driving sleeve, then lower transmission to floor.

7) If front oil pump drive sleeve remained in the torque converter hub when transmission removed, remove the sleeve and inspect. Check driving lugs and machined surfaces for burrs and wear. Check ring for broken ends and freeness in ring groove.

TRANSMISSION INSTALLATION

1) Install guide studs C-3276 in the two upper transmission case-to-adapter screw holes. Lubricate front oil pump drive ring sleeve and bearing surface with Lubriplate and install in torque converter hub making sure drive lugs are properly engaged. Note position of driving lugs on front oil pump drive sleeve, then position front oil pump pinion in same way to aid in proper engagement when transmission installed.

2) Slide transmission over guide studs and into position. Make sure drive lugs on front oil pump drive sleeve properly engage front oil pump pinion. *(CAUTION—To avoid damage to front oil pump, do not attempt to use transmissoin-to-adapter screws to bring transmission and adapter together. If oil pump drive sleeve and input shaft have been properly aligned, the transmission should slide into position relatively easy. DO NOT FORCE.)*

3) Install the two lower transmission-to-adapter screws and lock washers, do not tighten. Remove guide studs and install the two upper transmission case-to-adapter screws and lock washers, then draw all four down evenly and tighten to 45-50 ft. lbs. torque.

4) Place cross-member into position and install crossmember-to-frame bolts, tightening them to 50-55 ft. lbs. torque. Lower engine and at same time align mounting holes in extension of transmission with holes in crossmember. Install the two nuts and lockwashers that hold engine rear support insulator to crossmember and tighten to 30-35 ft. lbs. torque. Remove support fixture from side of frame member.

5) From this point, reverse the removal procedure as indicated above. Refill transmission and adjust manual and throttle control linkage. *See "Manual & Throttle Control Linkage" above.*

TORQUE CONVERTER REMOVAL

1) With transmission removed, turn front wheels to extreme right and remove starter motor. Remove the transmission case adapter screws and lockwashers and remove transmission from car. Remove Remove lower half of flywheel housing.

C NTINUED ON NEXT PAGE

POWERFLITE (C nt.)

►*NOTE:* If torque converter being removed because of excessive runout damage, check by using dial indicator on hub and mark the highest point of runout on both converter and crankshaft flange. The reason for this is so it may be determined later if runout was caused by the converter or crankshaft, after crankshaft has been checked in the same manner.

2) Using tool C-811, remove the eight torque converter stud nuts and lockwashers from crankshaft flange. Remove torque converter from crankshaft.

►*NOTE*—Check crankshaft flange runout. Maximum is .002".

STARTER RING GEAR REPLACEMENT (REMOVAL): Support torque converter assembly in a vise and carefully remove staking lugs, retaining ring gear to torque converter, with a file *(CAUTION*—Be careful when supporting torque converter in vise to avoid distortion). Place torque converter on blocks of wood, and using a blunt chisel or drift, tap around ring gear until it comes off converter.

Installation of Ring Gear—Remove burrs or raised spots on torque converter with a file, being careful not to remove more metal than is necessary. Any of the following methods for expanding the ring gear can be used in the manner outlined.

Oven—Set temperature at 150° and allow ring gear to remain for 15 to 20 minutes.

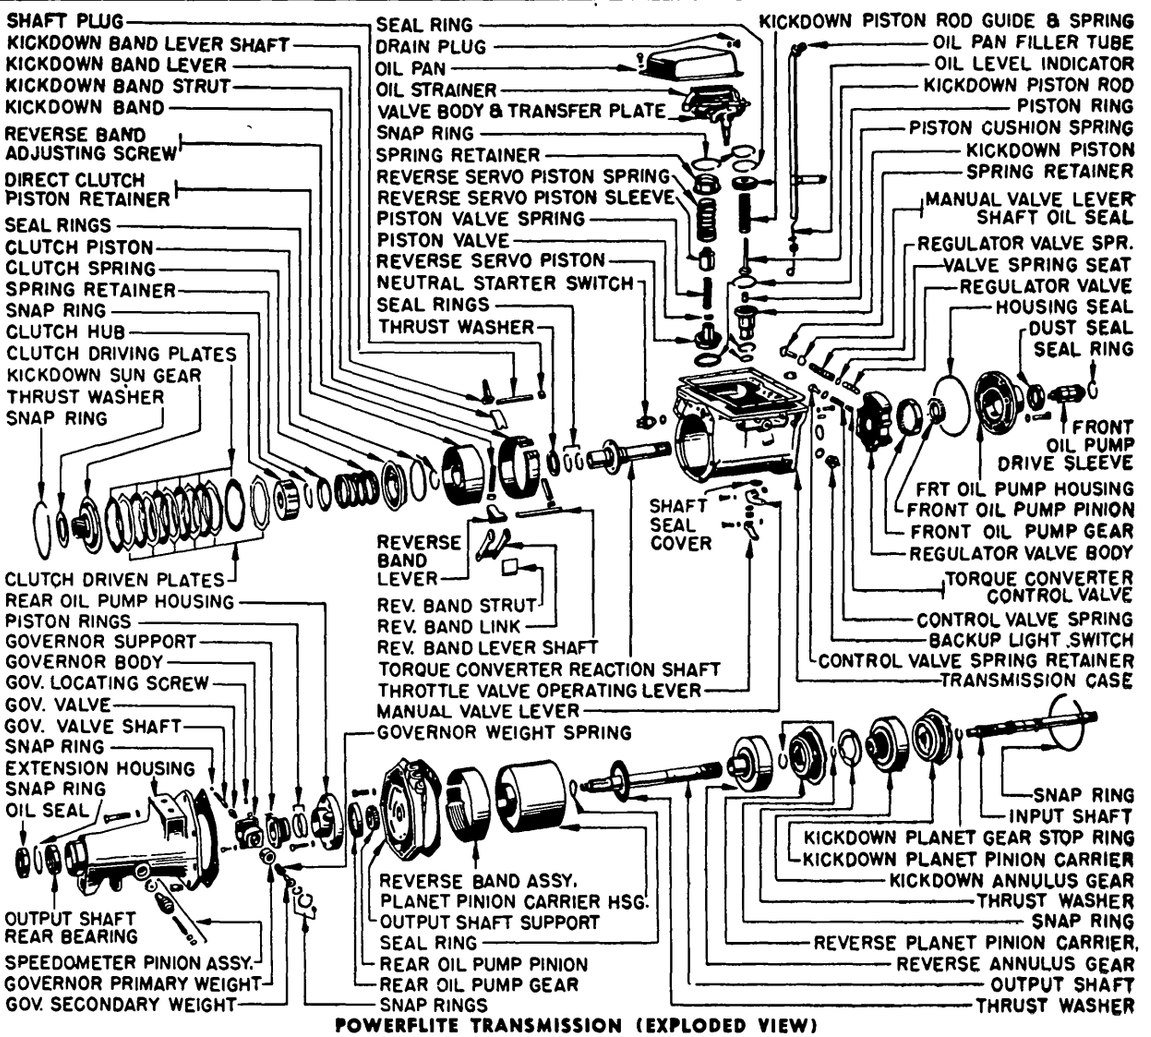
Boiling Water—Place ring gear in shallow container, add water and heat for approximately two minutes.

Flame—Place ring gear on a flat surface. Using a medium size tip, direct a slow flame around inner rim of gear, being careful not to direct flame onto teeth of ring gear. Place a few drops of water on face of gear at short intervals during heating process. When gear is hot enough to boil the drops of water, installation of gear to torque converter can be made.

When gear properly expanded, proceed as follows: Place starter ring gear over flange surface of torque converter, making sure that rear face of gear contacts flange on torque converter evenly around the entire diameter. Reweld ring gear to torque converter, ***using extreme care to place as nearly as possible the same amount of metal in exactly the same locations as original assembly.*** This is necessary to maintain proper balance of the unit. Place weld alternately on opposite sides of the converter to mimimize distortion. Clean thoroughly before installing in car.

►*RING GEAR WELDING NOTE:* Use a welding current of 200 amps. and 5/32" Fleet-Weld No. 27, or General Electric No. W28 rod, or their equivalent.

►*WELDING CAUTION:* To prevent burning through the torque converter, the arc should be directed at the intersection of gear and housing from an angle of approximately 45° from the face of the gear. DO NOT GAS WELD.



TORQUE CONVERTER INSTALLATION

►*TORQUE CONVERTER HUB RUNOUT NOTE:* When torque converter assembly is removed for any reason from crankshaft drive flange, the converter assembly runout should be checked when reinstalled. There are two methods for adjusting the hub runout. *See "Torque Converter Hub Runout Adjustment" below.*

1) Inspect mating surfaces of torque converter and crankshaft flange for burrs and dirt. Install torque converter on crankshaft flange. Install eight torque converter stud nuts and draw down evenly and tighten. Install lower half of flywheel housing and starter motor.

2) Install transmission case adapter on flywheel housing and tighten to 25-30 ft. lbs. torque. Install transmission (see above). Refill torque converter as follows:

3) Fill transmission with Automatic Transmission Fluid (Type A) to "full" mark on dipstick. This will take approximately 5 qts. Run engine at idle speed in neutral for approximately two minutes, then add 8 qts. of fluid to bring oil level to "full" mark on dipstick. Allow engine to run until normal operating temperature is reached. Set handbrake and shift selector lever through all ranges and return it to "N", recheck level and add fluid to bring level to "full" mark. *CAUTION—Fluid should NOT BE ABOVE THE FULL MARK.*

POWERFLITE TRANSMISSION (EXPLODED VIEW)

TORQUE CONVERTER RUN- UT ADJUSTMENT

►*NOTE—Two methods, as follows, can be used to adjust torque converter run-out.*

Heat Method: *(CAUTION—When using this method, extreme caution must be used to prevent burning the metal and causing irreparable damage. Sufficient heating of this unit, to cause the necessary drawing of metal required, is accomplished in just a few seconds. DO NOT OVERHEAT).* Remove transmission, torque converter housing and dust shield. Mount Torque Converter Hub Alignment Indicator C-430 on adapter plate. Rotate converter through 360° and mark high point on converter with chalk, then rotate converter to move the high point to the top. Apply heat 180°

C NTINUED N NEXT PAGE

POWERFLITE (C nt.)

from the high point at opposite side of converter shell at **high point of radius**. Use a No. 3 acetylene torch burner, moving the flames at all times in a circular motion about the size of a dime. When the spot begins to change color remove the flame and quench the converter with a water soaked rag. Change rags several times (the more quickly converter is cooled, the greater the drawing on the metal). Before checking hub runout make certain that both sides of the converter are the same temperature. If runout exceeds .004" at the same point, repeat operation. *(CAUTION*—It is possible to draw the metal excessively, thus causing runout at opposite side. If this occurs, reheat converter 180° from original point).

Shim Method: Determine hub runout in the same manner as for "Heat Method" above. Loosen converter drive flange nuts sufficiently to insert shims of proper thickness 180° from indicated high point. The thickness of shims used should equal half the total indicator reading, shim thickness not exceeding .008". New shims are furnished in the following sizes. Part No. 1610442 (.002"), 1610443 (.003), No. 1610444 (.005").

TRANSMISSION OVERHAUL DISASSEMBLY

1) Place transmission assembly in stand C-3280 and turn upside down. Remove oil pan and gasket. Loosen throttle and manual control lever locking screws and slide levers off shafts. Remove throttle valve camshaft felt retainer and felt and manual valve lever shaft seal cover. Inspect these parts for wear.

2) Remove oil strainer support screws and remove oil strainer assembly. Inspect ring seals located at both outlet sides of strainer. Remove transfer plate screws and take off valve body and transfer plate assembly. *See "Valve Body & Transfer Plate Overhaul" below.*

►*CAUTION: Mating surfaces are machined and extreme care must be used to avoid damage to these parts.*

3) Remove neutral safety switch and back-up light switch and gaskets.

4) Check transmission end clearance with a dial indicator or feeler gauge by prying direct clutch assembly toward rear and measuring the distance between direct clutch and carrier housing. Pry direct clutch forward and again measure the distance between direct clutch and carrier housing. Clearance should be .043-.069". If not within limits, record the measurement for reference at reassembly.

Hand Brake Assembly: Using tool C-3281 to hold transmission to flange, remove transmission flange nut and washers. Attach puller C-452 and remove brake drum assembly. Inspect oil sealing surfaces, and lining surfaces on drum for scoring or wear. Remove transmission brake support grease shield spring (NOTE—this spring acts as a guide for the brake shoes and retains the brake support grease shield to transmission extension housing). Place a rubber band around brake shoes to hold them in position and remove brake shoe return spring. Remove brake anchor shoe washer and brake shoe guide. Remove both brake shoe assemblies, adjusting sleeve, nut, screw and brake shoe operating lever link. Remove brake support grease shield from extension housing. *(CAUTION*—If a screwdriver or sharp instrument is used to remove the shield, care must be taken not to damage neoprene sealing surface at bottom of shield). Slide brake support assembly from rear extension housing and anchor. Inspect neoprene spacer for deterioration and note the steel sleeve used between spacer and extension housing.

Transmission Extension: Remove speedometer drive pinion. *(CAUTION—Nylon gear can be damaged if extension housing is removed without first removing the speedometer drive pinion).* Using puller C-748, remove the output shaft rear bearing oil seal and remove any burrs from counterbore of extension housing. Remove the transmission-to-extension screws and lockwashers. Install guide studs C-3283 and attach puller C-3282. Pull extension housing from output shaft support assembly and remove extension gasket. *(CAUTION*—Use care when removing extension housing to prevent damage to governor housing). Inspect extension housing for cracks in casting and remove burrs from gasket surface. Clean output shaft rear bearing and dry with compressed air. Check bearing for rough spots but do not remove from housing unless it is found to be defective. Using a pair of long nose pliers, remove output shaft rear bearing snap ring. Using driver C-3275, drive output shaft rear bearing out rear of extension housing. Remove vent from top of extension housing and make sure it is clear of foreign matter and is open.

Governor: Using a sharp instrument, remove either of the governor valve snap rings. Remove governor valve shaft and valve from governor body. With snap ring-pliers, remove governor weight assembly snap ring (large), and remove governor weight assembly from governor body. Using C-3229 pliers, remove governor secondary weight snap ring. *(CAUTION*—Keep thumb pressure against secondary weight when removing snap ring as it is spring loaded). Remove secondary weight and spring. Inspect all parts for burrs or wear. Check secondary weight for free movement in primary weight by placing secondary weight in primary weight without spring. Primary weight should fall freely when both parts are clean and dry. Check spring for distortion. Remove governor locating screw from governor body and output shaft *(make sure that screwdriver used fits slot in screw perfectly to avoid damage to governor body).* Slide governor body and support from output shaft. Remove the two governor support piston rings and inspect closely. *(CAUTION*—Governor support has pressed in steel sleeve which routes oil through the support. Make sure these passages are open. Do not attempt to replace sleeve if damaged, replace support). Clean passages with air and inspect valve and governor body for slight scores. Remove the four governor body-to-support screws and lockwashers and separate body from support.

Rear Oil Pump: Remove oil pump housing-to-output shaft support screws and lockwashers and remove housing and oil pump gear. Use prussian blue to mark front side of gear in housing *(DO NOT USE A SCRIBE).* Inspect machined surfaces for nicks and burrs, oil pump gear and housing for being scored or pitted, and pump housing plug for leaks. Remove rear oil pump pinion from output shaft and mark front side with prussian blue *(CAUTION*—Oil pump pinion keyed to shaft by a small ball. Use care when removing pinion not to lose ball). Check pinion keyway and ball pocket for pitting or scoring. Using tool C-3335 and feeler gauge, check clearance between pump housing face and face of gears. Clearance limits are from .001-.003".

Center Assembly (Output Shaft Support, Planet Pinion Carriers, and Direct Clutch Assemblies): Remove output shaft support-to-transmission case screw and washer. With one hand, work output shaft up and down, and at the same time apply pressure with the other hand to the input shaft. Slide output shaft rear support assembly, planet gear housing assembly and gasket from rear of transmission case. If rear support is stuck to transmission case and cannot be removed as just described, then proceed as follows: Install one of the oil pan screws into transmission case and with the aid of a pry bar, pry against support sufficiently to separate support from case. Remove direct clutch piston retainer assembly from torque converter reaction shaft. Remove direct clutch piston retainer thrust washer from torque converter reaction shaft. This washer is a select fit and controls end clearance between direct clutch assembly and carrier housing. Inspect washer for cracks, burrs and wear.

►*1955 INPUT SHAFT PRODUCTION CHANGE: Seal rings not used in late production. See Production Change above.*

Planet Pinion Carrier Removal from Housing Assembly: Place unit in an upright position in tool C-3285. Using a feeler gauge, check clearance between kickdown planet pinion carrier housing snap ring and kickdown planet pinion carrier assembly. This clearance should be .012-.038". If within these limits, then identify each thrust washer as it is removed. Using a screwdriver, remove transmission kickdown planet pinion carrier housing snap ring. Identify snap ring to aid in assembly (ring is not a selective fit). Proceed as follows:

1) Remove input shaft, kickdown planet pinion carrier assembly and kickdown annulus gear from carrier housing. Remove reverse planet pinion carrier thrust washer and inspect for cracks, burrs and wear. Remove kickdown annulus gear snap ring. Remove kickdown annulus gear from input shaft and inspect for worn, cracked or broken teeth.

2) Remove kickdown planet pinion carrier assembly from input shaft and carefully inspect stop ring on end of shaft which controls position of annulus gear on input shaft. Check all oil passages in both gear and shaft for obstructions. Inspect splines and bearing surfaces for burrs and wear. On early cars, inspect the three seal rings on input shaft for broken ends and make sure they are free to rotate in grooves.

3) Inspect planet pinion carrier for scores on thrust surfaces, broken and worn teeth. Using a feeler gauge, check end clearance on individual planet gears, clearance should be .006-.017". Inspect pinion shafts for tight fit in carrier and make sure pinions are free to rotate on shafts. Check oil holes in gears and shafts for obstructions. Inspect oil holes in the thrust washer of the kickdown carrier to make certain they are open *(NOTE—Do not replace planet pinion carrier assembly unless the above inspection indicates that it is necessary. This assembly is serviced only as a complete unit).*

4) Remove reverse planet pinion carrier assembly from planet pinion carrier housing. Inspect in the same manner as for planet pinion carrier (3 above).

CONTINUED N NEXT PAGE

POWERFLITE (C nt.)

Remove output shaft and reverse annulus gear assembly from carrier housing and output shaft support. Remove reverse annulus gear snap ring and remove annulus gear from shaft. Inspect thrust surfaces, journals and inner bushings for scores. Check annulus gear for worn or broken teeth. Inspect ring grooves for burrs and ring for broken ends. Inspect splines on both shaft and gear for burrs and wear. Check speedometer pinion gear and gear output shaft, and shaft bushing for burrs, wear and scoring.

5) Remove planet pinion carrier housing thrust washer and check for cracks or wear. Remove planet pinion carrier housing from output shaft support and inspect driving lug slots inside of housing for wear. Inspect bearing and thrust surfaces for scores and burrs. Closely inspect band contacting surface for burned spots and scoring, especially if lining has worn excessively. Inspect all oil passages in output shaft and support for obstructions. Check rear oil pump mating surface for burrs and scores, and check for stripped threads in support.

Direct Clutch Piston Retainer: 1) Using a screwdriver remove kickdown sun gear snap ring. Identify this ring so it can be returned to the same position (selective fit). Lift out sun gear assembly. Check for clutch material obstructing oil passages and slinger and remove any metal pickup which might have accumulated on front side. Inspect for cracked or broken teeth.

2) Lift out direct clutch hub from center of direct clutch piston retainer. Inspect driving lugs for wear and remove any metal pickup accumulated on either side of hub. Invert the direct clutch piston retainer and remove clutch plates (steel) and driving disc assemblies (five or six of each used, depending on car model), noting position in which these parts were assembled. *(CAUTION*—If assembly was started with cork portion on outer top, the same sequence will follow all through the assembly and when unit is reassembled the same sequence should be followed to assure smooth operation). Inspect driving discs for evidence of wear, burning, glazing, and flaking off of facing material. Check discs by scratching with finger nail and if material collects under nail, replace discs. Inspect splines in discs, replacing any that are damaged. Inspect steel plates for burning, scoring, or damaged splines.

3) Using tool C-3302, compress direct clutch spring sufficiently to unseat clutch spring retainer snap ring. Release tool C-3302, and remove direct clutch spring retainer snap ring, spring retainer and spring from direct clutch piston retainer. Using a twisting motion remove direct clutch piston assembly from clutch retainer. Air pressure may be used to blow piston out if it is tight.

4) Inspect ball check in clutch retainer housing to make sure it is free. The bearing used in direct clutch piston retainer is a steel back bronze type and is **not replaceable.** If torque converter reaction shaft seal rings have worn or grooved the bearing so that bronze is no longer visible at that point replace the direct clutch piston retainer. Inspect band contacting surfaces for deep scores and burns, especially if band lining is worn to point where steel band has been contacting direct clutch piston retainer.*(CAUTION—Do not turn clutch piston retainer in lathe to remove score marks).* Inspect steel clutch plate contacting surfaces for deep scores, replace as needed. Make sure clutch driving lugs will slide freely into retainer. Inspect inside bore for score marks, and if light, remove with crocus cloth, if heavy, replace piston.

5) With tool C-3286, unlock direct clutch piston retainer seal ring and remove from retainer. Inspect for wear and broken ends. Remove direct clutch piston seal ring (neoprene) from piston. Inspect for deterioration and hardness.

Reverse & Kickdown Band Assemblies: Mark reverse band for installation purposes, then compress ends of band sufficiently to remove reverse band strut. Unhook reverse band assembly from link assembly and remove by rotating band ends through rear opening in transmission case. Repeat with kickdown band, noting that strut is grooved to act as a guide to strut pin on band end. Remove from case in same manner as for reverse band. Inspect linings for wear and bonding to metal band. If lining is worn to point where grooves are no longer visible, replace band. *(CAUTION—Do not attempt to reline bands.)* Check bands for distortion and cracked ends.

Reverse & Kickdown Band Lever Assemblies: *(CAUTION—Inspect these link assemblies and levers for cracks or wear, making sure they have side clearance and are free to turn on shafts. Do not remove these assemblies unless inspection reveals that it is necessary).* If necessary to remove, proceed as follows: Insert finger in back of reverse band and link assembly lever shaft, and holding the reverse band lever and link assembly with the other hand, push shaft out rear opening in transmission case. Remove kickdown band lever shaft plug in front of transmission case and remove kickdown band lever in same manner as for reverse band, except that shaft is removed from front of transmission case.

Front Oil Pump: 1) Remove transmission regulator valve spring retainer, spring, gasket and valve. Remove torque converter control valve spring retainer, spring, gasket and valve.

2) Remove front oil pump-to-transmission case screws and washers (discard aluminum or copper sealing washers, new ones must be used at reassembly). Remove housing by tapping gently with a fibre hammer (if front pump housing has two threaded holes, attach puller C-3287 and guide studs C-3288 and pull housing and gears from transmission case). Use prussian blue to mark front side of gears *(CAUTION—Do not scribe gears for identification).*

3) Remove front oil pump housing seal (large neoprene) from housing, and inspect for deterioration and hardness. Using a brass drift, drive housing dust seal out front of housing. Inspect housing bushing for scores. Remove light scores with crocus cloth and if bushing scored heavily, replace housing (bushing is not replaceable). Check housing and gears for scores.

4) Using tool C-3335 and feeler gauge, check clearance between pump housing face and face of gears. Clearance limits are from .0012-.0022". Make sure all oil passages are clear by blowing out with compressed air.

Regulator Valv Body: Using the two holes provided in regulator valve body, attach puller C-3287, and install guide pins C-3288. Pull regulator body off torque converter reaction shaft. Place body and both valves in pan containing clean solvent, wash thoroughly and dry with compressed air. Check valves for free movement in body, these valves should fall in and out of bores when both valves and body are dry. *(CAUTION*—If crocus cloth is used to polish valves, care must be taken not to round off the sharp edges of valve.) Check for all passages for obstructions and all mating surfaces for burrs or distortion. If body has a slight nick or raised portion on a mating surface, it can be removed with a surface plate and crocus cloth. Check regulator valve spring seat (snap ring) for proper seating. Wrap valves and body in separate cloths until ready for installation.

Reverse Servo Piston: Lift out reverse servo piston sleeve. Inspect inside bore, lever, and contacting surface on piston sleeve for scores and wear. Make sure the two bleeder holes are open. Install tool C-3289 on transmission case and compress reverse piston spring retainer. Using a screwdriver, remove the reverse servo piston and valve assembly spring retainer snap ring, and loosen compressing portion of tool. Remove spring retainer, spring, servo piston and valve assembly. Remove servo piston ring (lip type neoprene) from piston and inspect for distortion and hardness. Remove reverse servo piston valve snap ring. Remove spring and valve from piston. Inspect servo bore for scores and remove light scores with crocus cloth.

Kickdown Piston: Using tool C-3289, apply sufficient pressure on kickdown piston rod guide and remove the snap ring. Loosen compressing portion of tool and remove tool from transmission case. Remove piston rod guide, piston spring, kickdown piston rod assembly, and kickdown piston cushion spring. Inspect riveting of kickdown piston rod to kickdown piston spring retainer. Remove seal ring from guide and inspect for light scores and wear on piston rod and guide. Using C-484 pliers, remove kickdown from transmission case. Remove the three snap rings (two locking and one open type) from kickdown piston. Inspect rings for scores or broken ends, and piston for wear.

Torque Converter Reaction Shaft: *(CAUTION—Inspect shaft seal rings (interlocking type) for broken ends and make sure they are free to rotate in grooves. Inspect inside of shaft for burrs, and splines for burrs and wear. Check thrust surfaces for wear and slight scores. Do not remove reaction shaft from case unless inspection reveals that it is necessary).* If shaft must be removed, proceed as follows: Remove shaft seal (neoprene). Using a suitable brass drift, remove shaft dowel pin from shaft flange and transmission case. Remove transmission case-to-reaction shaft screws and using tool C-3297, press shaft out of transmission case. Remove the two shaft seals (interlocking).

Manual Control Valve Lever Shaft Oil Seal: Drive seal out of case with a suitable drift.

Kickdown Band Adjusting Scr w: Loosen locking nut and remove kickdown band adjusting screw and locknut. *CAUTION—When locknut is loosened, the adjusting screw must be finger free. If not, inspect screw and nut for pulled threads or foreign material on threads. Freeness of this screw is very important to adjustment.*

Transmission Case Inspection: Inspect case for cracks, sand holes and stripped threads. Check for burrs on mating surfaces. Blow compressed air

CONTINUED N NEXT PA E

POWERFLITE (C nt.)

through all passages to make sure they are open. Check oil hole plugs for tightness.

REASSEMBLY

Kickdown Band Adjusting Screw: Install adjusting screw in transmission case until there is approximately 1" of screw left outside case. Do not lock screw into position at this time.

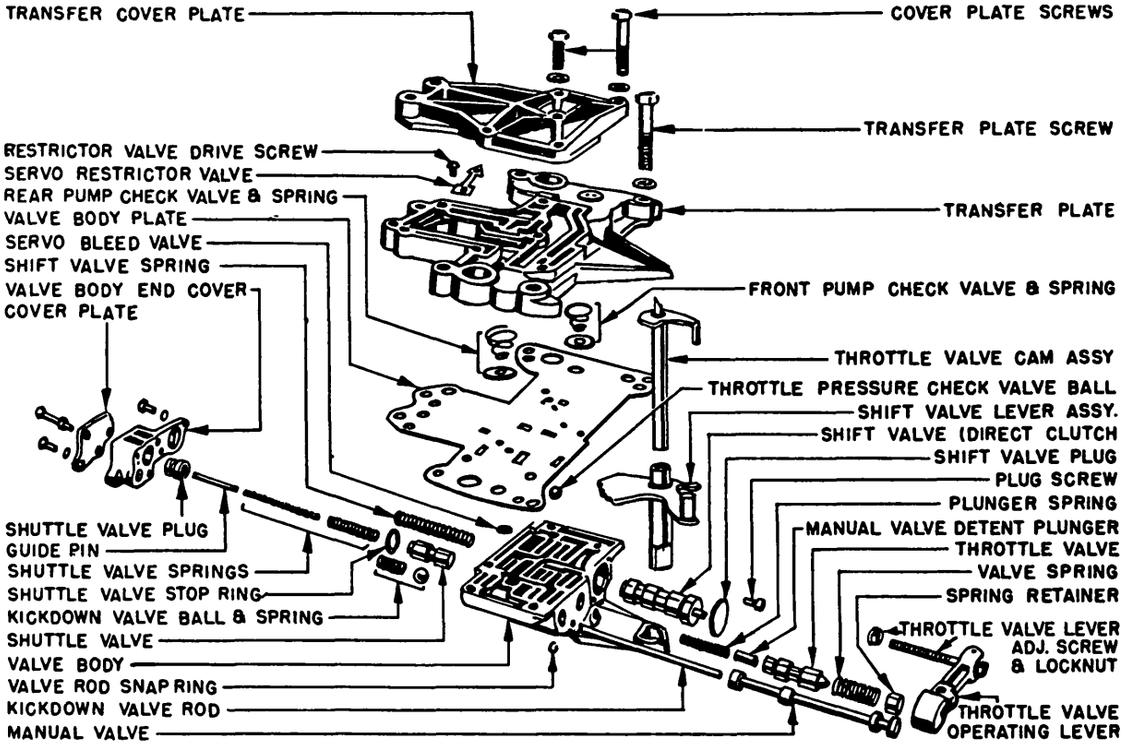
Manual Control Valv Lever: Using tool C-3277, start seal squarely and tighten until seal is flush with case.

Torque Converter Reaction Shaft: ***(NOTE—Reaction shaft should only be removed if inspection indicates that it is faulty).*** Heat front face of transmission case to 170-190°, using sun lamps for the purpose.

1) Coat the two shaft interlocking seal rings with Lubriplate and install on shaft and lock in place. Make sure the rings are free to rotate in lands. Coat the portion of shaft that presses into case with Lubriplate and position shaft into front of transmission so holes in shaft line up with screw holes in case.

2) Place a 5/16" (.308-.311" outside diameter in unthreaded section), 2¼" long bolt through dowel guide pin holes in case and reaction shaft to act as guide, install nut. Using tool C-3297 press shaft into place. Do not remove 5/16" bolt at this time. Start the three transmission case-to-reaction shaft screws and washers and tighten slightly, but do not torque.

3) Remove 5/16" bolt from dowel hole and install the reaction shaft dowel from inside case. Torque the case-to-reaction shaft screws to 10-15 ft. lbs. Coat neoprene reaction shaft seal and install on shaft.



Kickdown Piston: 1) Coat the three kickdown piston rings (two locking and one open type) with Lubriplate and install on piston. Lock into position and make sure they are free to rotate in lands. Place kickdown piston assembly into transmission case, compress bottom ring with a brass rod (flatten end), and push piston into place.

►***CAUTION: After bottom ring has entered, piston will seem to hang at two different locations while being pushed into case. This is due to rings entering cylinder. If any of the rings should be broken when piston assembly is being installed, transmission will not operate properly.***

2) Place cushion spring in piston and install tool C3289 on transmission case. Place piston rod assembly in piston and slide piston spring over piston rod assembly. Coat piston rod guide seal ring with Lubriplate and install on rod guide. Make sure ring rotates in groove.

3) Place piston rod guide assembly on piston rod assembly and using extreme care, compress the kickdown piston spring to the point where piston guide seal ring slightly binds on case. Using a piece of brass rod (flattened on end), work seal into position, gradually compressing spring until seal ring enters case and snap ring can be installed. Install snap ring, making sure it is properly seated.

R verse Servo Piston: 1) Place reverse servo piston valve and spring in reverse servo piston, with shaft protruding through hole in bottom of piston. Using pliers C-3229, install reverse servo piston valve spring snap ring and make sure it is seated.

EARLY 1954 POWERFLITE VALVE BODY & TRANSFER PLATE ASSEMBLY

2) Coat servo piston ring with Lubriplate and install on piston. Insert piston and valve assembly into transmission case in a cocked position, then by rotating piston, the piston ring will enter case without damage.

3) Place servo piston spring over piston and position spring retainer over spring. Compress spring with tool C-3289 sufficiently to install snap ring, making sure it is seated. Inspect interior of servo sleeve for burrs, then place sleeve over piston, making sure sleeve slides freely on piston by working it up and down. Remove installing tool from transmission.

Regulator Valve Body: 1) Inspect regulator valve body and valves to make sure that no damage has occurred since disassembly and blow out passages with air.

2) Coat reaction shaft seal (neoprene) with Lubriplate if not already done, and place regulator valve and torque converter control valve in regulator valve body. Install guide studs C-3288 in front transmission case.

3) Place regulator valve body assembly, with oil passages to rear, over reaction shaft and onto guide studs ***(CAUTION—When reaction shaft seal enters regulator body use care to prevent shaft screws damaging passages on regulator body)***, seat firmly to front of transmission case.

Front Oil Pump: 1) Position front oil pump housing dust seal in oil pump housing with metal portion of seal down. Using driver C-3278, bottom seal in housing. Coat housing seal (large neoprene seal) with Lubriplate and install on housing.

2) Place front oil pump gear and pinion (driving lugs on pinion facing up, and prussian blue marks made at time of disassembly toward front) in pump housing. ***(CAUTION—Oil pump pinion must be installed correctly or damage will result when installed in transmission.)*** Lubricate pump gears with transmission fluid.

3) Place pump housing assembly over reaction shaft and slide into position over guide studs until pump housing seal is flush with transmission case. Using new aluminum or copper washers on screws, start five of the screws and **draw housing down evenly** until it is seated into transmission case. Remove guide studs and install two remaining screws and washers. Torque all screws to 12-17 ft. lbs. ***NOTE—After all screws have been installed and torqued, engage driving lugs of oil pump pinion to determine if pinion turns freely. Use the oil pump drive sleeve for this check. If not free, remove pump and check for foreign matter between gears and housing.***

4) Using a new gasket, install torque converter control valve spring and retainer. Torque to 35-40 ft. lbs. Install regulator valve spring and retainer, using a new gasket, and torque to 45-50 ft. lbs.

Reverse Band, Kickdown Band & Lever Assemblies: ***NOTE—If lever assemblies were not removed, omit the operations covering their installation.***

1) Place kickdown band lever assembly in trans-

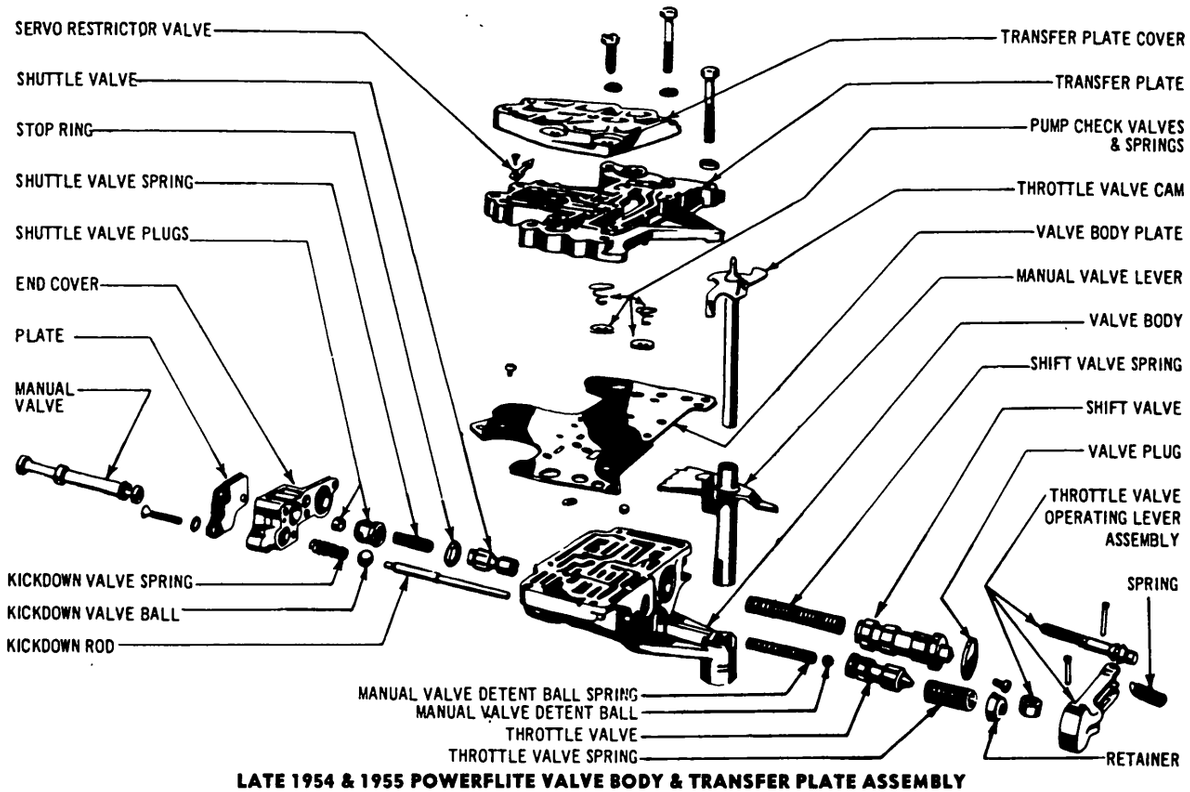
C NTINUED ON NEXT PAGE

POWERFLITE (Cont.)

mission case and slide band lever shaft into position from front of case, making sure it operates freely. Install band lever shaft plug and torque to 30-35 ft. lbs. Place kickdown band assembly into transmission case by rotating ends of band through opening in case. Fit proper end of band over adjusting screw and compress band sufficently to install band strut between other band end and band lever. ***CAUTION—Make sure band strut slot engages with kickdown band strut pin in band end.***

2) Place reverse band lever assembly in reverse band link assembly and position into transmission case, aligning holes in lever and link assemblies to holes in transmission case. Slide band lever shaft into position from rear of transmission case. Shaft is held in position by rear output shaft support.

3) ***(NOTE—If new reverse band is to be installed, back adjusting screw out until approximately 1" of screw is above lever on locknut side.)*** Place reverse band assembly into transmission case by rotating ends of band through rear opening in case. Hook correct end of band (previously identified when band removed) in link assembly. Compress band sufficiently to install band strut in slots of reverse band and band lever assembly.



Direct Clutch Piston Retainer: 1) Coat direct clutch seal ring with Lubriplate and install on piston, with lip of ring facing away from the flange. Coat clutch piston retainer seal ring with Lubriplate and install on retainer hub. Using tool C-3286, lock seal into position and make sure it is free to rotate in lands. Place piston assembly in clutch retainer, and with a twisting motion, seat piston in bottom of retainer, being careful not to damage lip of seal.

2) Seat clutch spring into piston retainer and position spring retainer and snap ring on spring. Using tool C-3302, compress clutch spring sufficiently to seat the snap ring. *NOTE*—Piston spring retainer may require guiding past the snap ring grooves. Make sure snap ring properly seated.

3) Place clutch hub in center of clutch piston retainer. Lubricate all clutch plates and driving discs with automatic transmission fluid and assemble by placing one of the clutch plates in clutch piston retainer, followed by a driving disc. ***(NOTE—Install discs in the same manner they were removed. If first driving disc was installed with cork portion on outer top, then the remaining discs must be installed in the same manner, or vice versa. Repeat this procedure until all six discs and plates have been installed.)***

4) Place kickdown sun gear assembly in direct clutch piston retainer and install snap ring (this ring is a selective fit and must be checked as follows): Using a feeler gauge, check clearance under kickdown sun gear snap ring. Clearance limits should be as close to zero as possible. Rings are furnished in three sizes for selective fitting. Part No. 1327729 (.059-.061"), No. 1327730 (.062-.064"), No. 1327731 (.065-.067").

Planet Pinion Carriers: 1) Place output shaft support in tool C-3285 with bearing surface up. Lubricate bearing surface of planet pinion housing and place bearing surface of housing over output shaft support bearing surface. Place reverse annulus gear on output shaft and install snap ring. (Output shaft may be placed in vise, providing vise is clean and equipped with brass jaws). ***(CAUTION—Reverse annulus gear must be tight fit on shaft. End clearance is controlled by various snap rings which are furnished in the following three thicknesses: Part No. 1329608 (.078-.080"), No. 1329609 (.082-.084"), No. 1329610 (.086-.088"). Make sure that snap ring is properly seated.)***

LATE 1954 & 1955 POWERFLITE VALVE BODY & TRANSFER PLATE ASSEMBLY

2) Coat output shaft seal ring with Lubriplate and install on shaft. Lock into position and make sure ring rotates freely in groove. Coat planet pinion carrier housing thrust washer with Lubriplate, slide over output shaft and into position in reverse annular gear. Place output shaft and reverse annulus gear in position in carrier housing and through output shaft support, being careful not to damage shaft seal ring as it enters shaft support. ***Check to see that planet pinion carrier thrust washer seats properly between annular gear and carrier housing.***

3) Lubricate thrust surfaces and gear teeth of reverse planet pinion gear and carrier assembly, and place carrier assembly in reverse annulus gear. ***(CAUTION—Make sure driving lugs on carrier assembly properly engage slots in planet pinion housing.)***

4) On early cars, coat input shaft seal rings with Lubriplate and lock into position, making sure rings rotate freely in lands. (Later cars have a large bearing area (bushing) on shaft replacing the three seal rings. ***See "Input Shaft Production Change" above for installation of later type shaft in early cars). (CAUTION—Inspect stop ring for proper position in input shaft groove).*** Lubricate thrust surfaces and gear teeth on kickdown planet pinion gear and carrier assembly. Slide assembly with collector ring up, carefully down on rear end of input shaft and over stop ring. Lubricate teeth and thrust surfaces and install kickdown annular gear onto input shaft, down to stop ring. Install kickdown annulus gear snap ring and make sure it is seated (Input shaft can be installed in vise providing it is clean and equipped with brass jaws).

5) Engage teeth of kickdown planet pinion gears with teeth on kickdown annulus gear. Slide pinion gear and carrier assembly into position in kickdown annulus gear. Coat reverse planet pinion carrier thrust washer with Lubriplate and install on kickdown annulus.

6) Place kickdown planet pinion carrier assembly, annulus gear and input shaft into position in planet carrier housing. Make sure planet pinion carrier thrust washer remains on annulus, and driving lugs on carrier assembly properly engage slots in planet pinion housing. Install planet pinion housing snap ring (not selective fit), making sure it is positioned and seated properly. Lubricate gears and splines.

7) Using a feeler gauge, check clearance between kickdown planet pinion carrier housing snap ring and the kickdown planet pinion carrier assembly. Limits are .012-.038". If not within these limits disassemble and recheck reverse planet pinion carrier and planet pinion carrier housing thrust washers.

Center Assembly (Output Shaft Support, Planet Pinion Carriers, and Direct Clutch Assemblies): 1) Coat kickdown planet pinion thrust washer with

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

Lubriplate, place over kickdown sun gear and on to thrust surface of direct clutch piston retainer assembly. Place direct clutch piston retainer assembly over input shaft, engaging sun gear with kickdown planet pinion gears and engaging splines of input shaft with direct clutch hub. Make sure kickdown planet pinion carrier thrust washer remains in position.

►*DIRECT CLUTCH PISTON RETAINER THRUST WASHER CAUTION:* This thrust washer controls transmission endplay clearance and is a selective fit. After transmission is reassembled, except for hand brake assembly, the endplay clearance must be checked and corrections made in the washer thickness as necessary. *See "Checking Transmission Endplay" below.*

2) Coat direct clutch piston retainer thrust washer with Lubriplate and install on torque converter reaction shaft inside transmission case. Use care when sliding washer over rings to prevent damage.

3) Install guide studs C-3283 in rear of transmission case, position new output shaft support gasket over guide studs and on to case. Place tool C-3306 over splines on front of input shaft.

4) Insert input shaft, with direct clutch assembly, planet pinion carrier housing, output shaft support and output shaft attached, through rear of transmission case and through transmission reaction shaft. Then guide assembly through bands and over guide studs into position in transmission case. Remove tool C-3306 from front of input shaft.

►*CAUTION: Do not force assembly into case. Avoid damage to seal rings on torque converter reaction shaft.*

5) Install one output shaft support-to-transmission case screw and lockwasher finger tight.

Rear Oil Pump: 1) Coat oil pump pinion ball with Lubriplate and insert in ball pocket in output shaft. Lubriplate oil pump drive pinion, place over shaft and slide into position, aligning keyway in pinion with ball in shaft. *Make sure pinion is installed with side marked with prussian blue at disassembly, is toward front.*

2) Slide pump housing assembly over output shaft and into position against output shaft support. Install five rear oil pump housing-to-output shaft support screws and lockwashers. *(CAUTION—There are two extra holes in housing which are used for vents. Make sure screws are not installed in these holes. Check each screw hole before installing screws).* Draw screws down evenly and tighten to 15-20 ft. lbs. torque. When screws have been properly tightened, check output shaft for free rotation of pump gears. If not free, disassemble pump to determine cause.

Governor: 1) Coat the two governor support piston rings with Lubriplate and install on governor support. Stagger rings and make sure they are free. Position governor body on support, install the four screws and lockwashers *but do not tighten at this point.*

2) Slide governor support and body assembly over output shaft and into position in rear pump housing, compressing governor support piston rings with fingers as support enters oil pump housing.

3) Align locating hole in output shaft to locating screw hole in governor body and install governor locating screw, tighten to 3½-4 ft. lbs. torque. *NOTE—Holes can be easily aligned by turning output shaft and holding governor body. Make sure screw driver attachment fits the screw slot when tightening locating screw.*

4) Tighten the four governor body screws to 5-10 ft. lbs. torque.

5) Dry governor parts with compressed air but do not lubricate when assembling. Place governor weight spring over secondary weight and position both in primary weight, making sure springs seat properly. Guide secondary weight, and compress governor weight spring sufficiently to install snap ring. Make sure ring is properly seated. Place governor weight assembly, with secondary weight snap ring up, into governor body and install snap ring, making sure it is seated.

6) Slide governor valve, with small end up, over governor valve shaft. Slide governor shaft into governor body through output shaft and governor weight assembly, at same time positioning valve into body. Install governor shaft snap ring and make sure it is securely locked to shaft. Check operation of governor weight assembly and valve by turning output shaft. Both should fall freely in body.

Transmission Extension: *NOTE—If output shaft rear bearing was not removed, omit operation covering its installation.*

1) Using driver C-3204, install output shaft rear bearing in extension housing. Make sure it is properly seated then lubricate with automatic transmission fluid. Install output shaft bearing snap ring, bevel side up, making sure it is properly seated.

2) Replace extension breather and tighten to 10-12 ft. lbs. torque. Install new transmission extension gasket over guide studs and into position against output shaft support. *Do not use sealing material on gasket.* Using care not to damage governor housing, place extension housing over output shaft and onto guide studs. Using tool C-496 with adapter C3284, press extension housing into position against output shaft support.

3) Start the seven transmission extension-to-case screws and lockwashers, then draw down evenly and tighten to 25-30 ft. lbs. torque. Tighten output shaft support-to-case screw to 25-30 ft. lbs. torque. *Check to see that output shaft turns freely.*

4) Coat nylon gear and threads on speedometer drive pinion with Lubriplate and install in extension. Tighten to 40-45 ft. lbs. torque.

Checking Transmission Endplay: Using dial indicator C-430 or feeler gauge, measure the distance between direct clutch assembly and carrier housing when clutch is in **rearward** position. Using a screwdriver inserted between the direct clutch assembly and carrier housing, carefully pry direct clutch **forward**. Remove screwdriver and measure again. The difference in measurements is the end clearance and must be .043-.069". If it does not fall within these limits, proceed as follows:

1) Remove the seven screws and lockwashers from transmission extension and install guide studs C-3283. Then remove the one output shaft support-to-case screw and washer, and remove extension housing, output shaft, support, and planet pinion carrier housing assembly as a unit.

2) Slide direct clutch piston retainer from torque converter reaction shaft and remove direct clutch piston thrust washer. Using a micrometer, measure thickness of the washer and then select a washer to give correct clearance. These washers are available in the following five thicknesses: Part No. 1406442 (.125-.130"), No. 1406443 (.135-.140"), No. 1406444 (.145-.150"), No. 1406445 (.155-.160"), No. 1406446 .164-.170").

3) To install, reverse removal procedure. Using driver C-3205, install output shaft rear bearing oil seal.

Hand Brake Assembly: 1) With brake support spacer in position on back of brake support and spacer sleeve in center of support, slide brake assembly over rear extension housing and anchor pin. Make sure spacer sleeve remains in center of support. Install brake support grease shield on extension housing. *NOTE—Indent in shield for correct positioning on extension housing. Shield must be located on housing far enough to permit installation of spring later.*

2) Place both anchor brake washers on brake shoe anchor and install locking washer. Place both shoe assemblies with adjusting sleeve nut and screw into position on anchor. Make sure brake shoes are between the anchor washers. Use a rubber band around shoes to help hold them in position.

3) Install operating link (marked for correct installation), and brake shoe support grease shield spring (with opening in spring toward adjusting sleeve). Make sure spring is properly seated in groove. Slide brake shoe return spring behind grease shield spring and hook into position in holes in brake shoes.

4) Make sure adjustment is loose enough and install brake drum assembly. If necessary, use tool C-496 to press brake drum on output shaft. Install transmission flange washer, shakeproof washer and nut, and tighten to 140-160 ft. lbs. torque.

Kickdown Band Adjustment: Turn transmission on side and using tool C-3291, loosen locknut and tighten kickdown adjusting band adjusting screw to 60-72 inch lbs. torque. With the counter on C-3291, **back adjusting screw out 3 turns,** then holding adjusting screw stationary with short handle, tighten locknut securely. *Use extreme care to assure correct adjustment.*

Reverse Band Adjustment: Remove reverse band adjusting screw locknut and tighten adjusting screw to 20-25 inch lbs. torque, then back out adjusting screw 10 turns. Holding adjusting screw in this position, replace adjusting screw locknut and tighten to 30-35 ft. lbs.

Valve Body & Transfer Plate: 1) Install neutral safety switch, back-up light switch and gasket, and tighten to 15-20 ft. lbs. torque. Clean mating surfaces and check for burrs on transmission case and valve body. Place valve body and transfer plate into position on transmission case and install five transfer plate screws and lock washers *(Install the two 1⅝" long screws through transfer plate cover on valve body),* tighten to 12-17 ft. lbs. torque. Make certain the two oil strainer tube seals are in position on oil strainer, and place oil strainer in position on valve body. Install oil strainer support screws and lock washers and tighten to 12-17 ft. lbs.

2) Place manual valve lever shaft seal cover over manual shaft and install manual control lever with arm side of lever against cover, on manual valve shaft. Tighten locking screw. Place throttle valve camshaft felt and retainer over throttle valve shaft. Install lever assembly on throttle camshaft, and

C NTINUED ON NEXT PAGE

POWERFLITE (C nt.)

tighten locking screw. Check operation of controls by shifting manual control into the four operating positions.

3) Check throttle cam position in throttle operating lever assembly and throttle camshaft assembly for kickdown operation. Visually check manual lever contact on neutral safety and back-up light switches.

4) Install oil pan, using a new gasket, and tighten attaching screws to 12-17 ft. lbs., drawing screws down evenly. Tighten drain plug to 20-25 ft. lbs. torque.

VALVE BODY OVERHAUL

Valve Body & Transfer Plate Disassembly: *(NOTE—Two different throttle valve assemblies used in production. Overhaul procedures are the same except as noted below).*

►*1954 SHUTTLE VALVE PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* A later type shuttle valve, Part No. 1643118 is used for production and can be used for service replacement. *CAUTION—* The adjusting screw on the later type shuttle valve is pre-set at the factory and *MUST NOT BE CHANGED IN THE FIELD.* When replacing the older type valve with the later one, DO NOT install the spacer and spring.

►*OVERHAUL CAUTION:* Place valve body and plate assembly in holding fixture C-3294. *DO NOT USE VISE TO HOLD TRANSFER PLATE ON VALVE BODY.*

1) Remove two of the long transfer plate cover screws and lock washers and install guide studs C-3295. Keeping finger tight pressure against transfer plate, remove the three remaining transfer plate cover screws, (two long & one short), and remove transfer plate cover. Using care not to lose the servo restrictor valve operating plug from transfer plate, remove transfer plate from valve body plate. *NOTE—Rear pump check valve has metering hole in it. Note position of this valve in relation to the front pump check valve (without metering hole).*

2) Remove valve body plate from valve body, noting position of throttle pressure check valve ball, and servo bleed valve (servo bleed valve may stick to valve body plate). Remove these parts and place in clean container. On later type valve assemblies remove throttle valve cam spring from cam and operating lever. On early and later type assemblies, compress the throttle valve operating lever assembly against throttle valve spring and slide throttle valve cam assembly from manual lever assembly. *(CAUTION—Remove any burrs from throttle valve camshaft and manual valve lever shaft before sliding them from valve body).*

3) Swing throttle valve operating lever out of way and remove throttle valve spring and retainer from throttle valve. Remove throttle valve from valve body core. Check distance from valve body to end of throttle valve operating lever adjusting screw. This distance should be 1 11/16". Using tool C-3279, remove throttle valve adjusting screw, lock nut and throttle valve operating assembly. *NOTE—It is not necessary to remove throttle valve operating assembly unless parts are to be replaced.*

4) Remove the four (three long and one short) valve body end cover plate screws and lock washers and remove valve body end cover plate. Remove valve body and cover screw, keeping pressure against cover to avoid losing the four springs (early type), three springs (late type) behind it. Carefully remove valve body cover so as not to lose any of the springs or kickdown valve ball. Remove shuttle valve plug *(CAUTION—Later type shuttle valve assembly has an adjustment screw. DO NOT CHANGE THIS ADJUSTMENT as it is pre-set at the factory).* Remove kickdown valve ball from body. Remove shuttle by using shuttle valve spring, and related parts (see illustration for parts in early and late type assemblies).

5) Remove direct clutch shift valve spring from valve body. Mark the direct clutch shift valve plug with prussian blue (in order to reinstall with right side out), then loosen plug screws sufficiently to allow removal of plug by pushing on open end of shift valve with finger. Remove shift valve, and remove valve body from tool C-3294. Place valve body on clean paper. On early type assemblies, remove kickdown rod snap ring and kickdown rod from valve body. On later type assemblies, remove kickdown rod from cover end of valve body.

►*MANUAL VALVE AND LEVER ASSEMBLY NOTE—It is not necessary to remove this assembly unless damaged parts are to be replaced. If assembly must be removed, proceed as follows:*

6) Place manual control valve lever on lever assembly and turn it counter-clockwise until manual control valve is in low range position (last detent). Using a screwdriver, compress detent plunger and spring and continue to turn manual valve lever assembly until manual valve becomes disengaged from manual valve lever assembly. Remove manual valve from valve body bore. Remove manual control lever and slide manual lever assembly from valve body. Remove manual valve lever detent plunger and spring from valve body.

Valve Body & Transfer Plate Inspection: Wash all parts in clean solvent and dry with compressed air. Check all passages for obstructions and check for porous coating. Inspect all mating surfaces for burrs and scratches. Light scratches and burrs can be removed with crocus cloth. With a light, check bores in valve body for pits and scores. Check springs for distortion and collapse. Check mating surfaces on a surface plate for distortion. Check all moving parts for free operation, and valves for freeness in body bores. Inspect servo restrictor valve in transfer plate to make sure it is seating properly. If valve is defective, carefully remove drive screw. Install new valve and new drive screw, making sure drive screw is tight, and being very careful not to distort transfer plate when installing drive screw. Check all points in valve for wear and replace defective parts.

Valve Body & Transfer Plate Reassembly: *CAUTION—When assembling valve body and transfer plate assemblies, handle parts carefully to avoid damage, such as nicks, etc., to mating surfaces. Use a twisting motion when placing valves in their respective bores.*

1) Place manual valve lever detent plunger spring and plunger into place in valve body. Slide manual valve lever assembly into valve body. Using a twisting motion place manual valve into valve body sufficiently to engage manual valve with manual valve lever pin. Then using valve lever assembly, turn slowly in clockwise direction and at the same time using a twisting motion, guide manual valve into valve body to low range position. Make sure detent plunger is seated.

2) Place kickdown rod (small end toward end cover) into valve body, making sure it is properly seated. Place valve body in tool C-3294 and install direct clutch shift valve. Place direct clutch shift valve into position (same as when removed, and with marks made at disassembly in correct position) in valve body. Draw the two screws down evenly and torque to 24-30 inch lbs. Install direct clutch shift valve spring in valve.

3) Install shuttle valve in valve body. Coat stop ring lightly with Lubriplate and place into recess in valve body. On early type assemblies place shuttle valve spring guide pin in shuttle valve and install both inner and outer spring over guide pin. On later type assembly place shuttle valve spring in valve. On both assemblies, install kickdown valve ball into valve body.

4) Place valve body end cover plate on end cover. Install one short screw and lock washer. Tighten securely. Place shuttle valve plug into position in end cover, and install kickdown valve spring. Install valve body end cover onto valve body. *CAUTION—* Make sure direct clutch shift valve, shuttle valve and kickdown valve spring are in correct position and properly seated when cover is being installed. Install valve body end cover screw and lock washer, but do not tighten.

5) Install the three (long) valve body end cover plate screws and lock washers. Draw down evenly and tighten to 24-30 inch lbs. Tighten valve body end cover screw and the remaining end cover plate screw to 24-30 inch lbs.

6) Using tool C-3279, install throttle valve adjusting screw, locknut and throttle valve lever assembly. Adjust to where there is approximately 1 11/16" distance between valve body and end of throttle valve operating adjusting screw. Install throttle valve (point outward) in valve body. Place throttle valve spring and retainer over throttle valves. Swing throttle valve operating lever over spring and retainer. Compressing the throttle valve lever assembly against throttle valve spring, slide throttle valve cam assembly into manual lever assembly, indexing cam portion on throttle valve in slot of operating lever. On later type assemblies, install throttle valve cam spring to cam and operating lever.

7) Install servo bleed valve and throttle pressure check valve ball into position in valve body and install guide studs. Position transfer plate cover on transfer plate and install the center screw (short) and lock washer finger tight. Install the servo restrictor valve operating plug (long end first) into transfer plate.

8) Make sure pump check valves and springs are properly positioned in transfer plate. The pump check valve with the metering hole should be toward the rear of transmission. Place valve body plate flush into position on transfer plate by compressing pump check valve springs. *CAUTION—Be sure pump check valves enter transfer plate, otherwise valve body plate will be damaged when assembly drawn down.*

9) Keep sufficient pressure on transfer plate and valve body to hold them together. Place over guide studs and into position on valve body, and install two of the transfer plate cover screws and lockwashers (one on each side) finger tight. Recheck to see that pump check valves remained in position in valve body plate. Remove guide studs and install two remaining transfer plate cover screws and lock washers. Draw transfer plate down evenly and torque all five screws to 45-50 inch lbs. torque.

POWERFLITE (CHRYSLER DE SOTO, DODGE, PLYMOUTH)

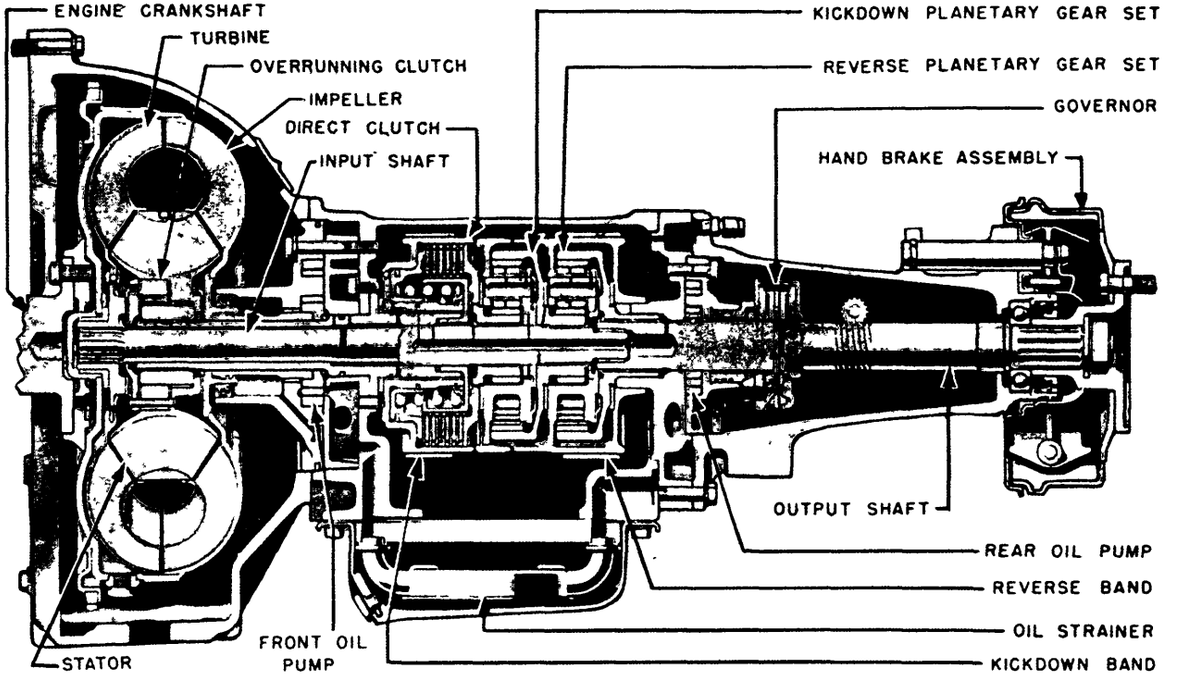
Chrysler (1956)
D Sot (1956-60)
D dg (1956-60)
Plym uth (1956-60)

►CHANGES, CAUTIONS, CORRECTIONS

►*PUSHING CAR TO START ENGINE:* Pushing is recommended rather than towing. With the "N" (Neutral) button pushed in, turn the key to "ON" position. When car reaches a speed of approximately 25 MPH, push in the "L" (Low) button. This will allow the transmission to crank the engine.

►*TOWING POWERFLITE CARS:* Following procedure recommended.

Transmissi n In perativ – Disconnect propeller shaft or tow car with rear end raised.



Transmissi n Op rating – The car may be safely towed at moderate speeds with the "N" (Neutral) button pushed in. For long distance towing (over 100 miles), the propeller shaft should be removed.

►*1956 NEUTRAL STARTER SWITCH PRODUCTION CHANGE:* On later production cars, the neutral starter switch contact plunger spring tension has been reduced (the effort required to depress spring on the new switch is 8 ozs., at .030" depression). To determine if switch is later type, check with finger pressure. An "O" ring seal and cupped washer is used with the new switch and the transmission case has been changed by having a 60° (included angle) countersink in switch assembly hole. The later type switch must be used only on transmission cases having the angle countersink in switch hole. *NOTE* – The "O" ring seal and washer may be used on early type switches in transmission case not having the countersink provided the tolerance stack-up permits proper adjustment of the switch without exceeding 75 ft. lbs. torque, in which case the original washer should be used. *S "Neutral Starter Switch Adjustm nt" und r "Manual Cable Adjustment" below.*

►*1956 POWERFLITE TRANSMISSION DRAIN PLUG ELIMINATED:* On later production cars, the drain plug has been eliminated. When necessary to drain the transmission, remove the filler tube connector at the oil pan.

►*1956 POWERFLITE DATE CODE NOTE:* Transmission building date is indicated by a code stamped on lower right side of case immediately after the transmission part number. Months are indicated by letters beginning with "A" (January), date and year by number.

►*1956 POWERFLITE PLANET PINION CARRIER (AND RELATED PARTS) PRODUCTION CHANGE:* On transmissions having a date code C-7-56 and later, aluminum planet pinion carriers are being used. The following parts are not interchangeable with previous transmissions: Kick-down Planet Pinion Carrier, Reverse Planet Pinion Carrier, Kick-down Annulus Gear, Reverse Annulus Gear, and Planet Pinion Carrier Housing. The Kick-down Annulus Gear used with aluminum pinion carriers can be identified by ¼" letters "A-L" stamped on flange. The later type Planet Pinion Carrier Housing is identified by a flat rear surface on housing (early type had a ridge machined on the rear, outer large diameter of the assembly). Dimensions of Reverse Annulus Gear are different from early type, and there are no special identifying marks on gear.

POWERFLITE TRANSMISSION SECTIONAL VIEW

►*1956 PLYMOUTH POWERFLITE TORQUE CONVERTER HOUSING & ADAPTER PLATE PRODUCTION CHANGE:* Dimensions have been changed on torque converter housings and adapter plates starting with Engine No. P-28-56973 and P-29-151148. Early and late type housings and adapters are not interchangeable The following table indicates dimensions for early and late types.

Part	Early	Late
Adapter Plate	① 3/4" thick	② 1 1/8" thick
Housing	③ 7 19/64"	③ 6 15/16"

① – Part No. 1613713 (P-28); 1613712 (P-29).
② – Part No. 1630850 (P-28); 1630841 (P-29).
③ – Measured from face-to-face.

►*1956 POWERFLITE THROTTLE VALVE AND SPRING PRODUCTION CHANGE (To Eliminate Valve Buzz or Flutter on Downshift):* A new throttle valve and spring (Service Pkg. No. 1752242) is being used in production and is available for service replacement. A chamfer on the reaction surface of valve, with a heavier valve spring eliminates valve buzz or flutter on downshift.

►*1956 POWERFLITE FRONT PUMP DRIVE SLEEVE & SEAL PRODUCTION CHANGE AND SERVICE REPLACEMENT NOTE:* A new front pump drive sleeve, Part No. 1630808, and drive sleeve seal, Part No. 1630809 is being used in production on transmission having a date code of A-23-57 and later (a letter "E" after the transmission part number also identifies this change). The later type "O" ring seal replaces the former metallic seal ring, and must be used in conjunction with the later type sleeve. It is preferable to use the early type drive sleeve and seal on transmissions built before the above date code.

►*1956 DESOTO ENGINE VALVE BENDING IN SERVICE (On cars having transmissions with date codes bef r B-9-56):* Valve bending results when the transmission downshifts at high speeds (above approximately 75 MPH). At the instant the downshift occurs, engine RPM is momentarily increased to a point where valve "pump-up" is encountered with consequent valve bending. To correct this condition, remove the rear pump housing and enlarge the .090" governor oil feed hole to 5/32" (governor oil feed hole is located in the smaller of the two depressions at ends of baffle under the pump gears). Check governor weight and valve for scoring and make sure governor has free movement after assembly. Adjust and correct push button control and manual shift lever. Check engine valve spring tension and replace springs not within specifications.

►*1956 POWERFLITE CLUTCH PLATE REPLACEMENT CAUTION:* The number of clutch plates and discs have been changed on some models. When replacing plates and discs, the same number should be used for replacement as those originally installed in transmission.

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

►*1956 DESOTO HISSING OR WHISTLING NOISE CORRECTION (In neutral or in forward driving ranges up to approximately 30 MPH):* Remove and disassemble valve body and transfer plate assembly. Remove rear pump check valve (one with small orifice in center) and discard the valve. Replace with a FRONT PUMP check valve in which a .030" square notch has been filed in the ridge on face of valve (a 32 tooth hacksaw blade can also be used to cut the notch). Use extreme care that only one notch is cut in the valve.

►*1956 PUSH BUTTON CONTROL ASSEMBLY PRODUCTION CHANGE:* Early type control with locking pawl replaced in production and for service with a later type having slide locks attached to slides, and no locking pawl. The later unit prevents possibility of releasing any one button until a newly selected gear range push button is completely engaged.

►*1957 POWERFLITE REVERSE SERVO PISTON PRODUCTION CHANGE:* All transmissions code dated C-5-57 and with the letter "B" preceding the part number will have a new reverse servo which incorporates a spring cushion instead of the hydraulic cushion previously used. New reverse band adjustment specifications are also used with the later type servo. See *"Reverse Band Adjustment Production Change" below.*

►*1957 REVERSE BAND ADJUSTMENT CHANGE (TRANSMISSIONS WITH LATER TYPE REVERSE SERVO PISTON ASSEMBLY):* See production change above. On transmissions having a code date of C-5-57 and with the letter "B" preceding the part number, adjust the reverse band as follows: Loosen locknut and tighten adjusting screw to 20-25 inch-pounds, then back off the adjusting screw **exactly 12 turns** (previous adjustment was 10 turns). Hold adjusting screw and tighten locknut to 30-35 ft. lbs.

►*1957 POWERFLITE REAR OIL PUMP PRODUCTION CHANGE:* A plastic rear oil pump gear and a revised oil pump housing are now being used in production. Transmissions having a code date L-19-56 and the letter "A" preceding the transmission part number stamped on lower side of case will have the later type pump assembly. The new pump parts (Gear, Part No. 1672315 & Housing Assembly, Part No. 1823666) are interchangeable with the previous parts if both the pump gear and housing are replaced together. The new plastic gear cannot be used in the old housing, and the old steel gear cannot be used with the later type housing.

►*1957 PLYMOUTH POWERFLITE TORQUE CONVERTER IDENTIFICATION:* Torque converters used on the 6 cyl. engine have a smooth surface at rear of converter (side nearest transmission). The V8 engine converter is identified by a 1 8" wide groove cut on the rear "donut"

►*1957 POWERFLITE RUNNING AWAY DURING PART THROTTLE DOWNSHIFT CORRECTION:* If this condition cannot be corrected by correct throttle linkage and kickdown band adjustment, remove main control valve assembly and examine throttle pressure lever for endplay between spherical surface of adjusting screw and positioning tab on throttle lever. If there is clearance at this point, bend tab against spherical surface of screw to eliminate all clearance *(CAUTION* - Be sure that lever moves freely on screw after bending tab). Examine servo restrictor valve (in valve body transfer plate), and replace if bent. Check servo restrictor valve plug for free movement.

►*1958 POWERFLITE TRANSMISSION THROTTLE VALVE PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE (To decrease possibility of engine running away during part throttle downshift):* Effective with transmission Date Code L-6-57 (transmissions also identified by a letter "F" preceding part number on right side pan rail), a new throttle valve and spring is being used in production and for service replacement. For transmissions before the above date code, install Throttle Valve and Spring Service Package, Part No. 1879506. *NOTE - Throttle pressure on all transmissions having the new type valve and spring must be adjusted to 13-15 lbs. (see "Throttle Pressure Adjustment" below).*

►*1958 ENGINE RUNNING AWAY DURING PART THROTTLE DOWN-SHIFT CORRECTION:* On transmissions having a date code before L-6-57, install Throttle Valve & Spring Package, Part No. 1879506 (see production change above). On all transmissions, correctly adjust throttle linkage and kickdown band, then if trouble is still not corrected, remove main control valve assembly and examine throttle pressure lever for endplay between spherical surface of adjusting screw and positioning tab on throttle lever. If there is clearance at this point, bend tab against spherical surface of screw to eliminate all clearance. *CAUTION - Be sure that lever moves freely on screw after bending tab.* Examine servo restrictor valve (in valve body transfer plate), and replace if bent. Check servo restrictor plug for free movement. Adjust throttle pressure to 13-15 lbs. *See "Throttle Pressure Adjustment"*

►*1958 FRONT OIL PUMP LEAKAGE CORRECTION:* Leakage around front pump bolt holes on transmissions built before April 14, 1958 (bolt holes not spot faced) should be corrected as follows: Dress area around holes with a file, then install new aluminum washers, pasting bottom of washers and area of hole with Permatex No. 2 Tighten bolts to 15 ft. lbs.

►*1959 POWERFLITE TRANSMISSION LUBRICANT PRODUCTION CHANGE & SERVICE REPLACEMENT NOTE:* Automatic Transmission Fluid Type "A", Suffix "A" should be used when draining and refilling transmission.

►*1959 POWERFLITE DRAINING & REFILLING INTERVAL RECOMMENDED CHANGE:* Drain & refill transmission with the recommended fluid every 10,000 miles. This supersedes the previous recommendation of 20,000 miles.

►*1959 DODGE & PLYMOUTH HARSH OR ERRATIC SHIFT CORRECTION:* This condition may be caused by a loose fitting accelerator shaft lever assembly (located on right side of bellcrank bracket on firewall). If a loose lever cannot be tightened by tightening the attaching nut, proceed as follows: Remove lever from accelerator shaft and bracket assembly and spread lever slot to 5/32". Install a .020-.030" thick by 5/16" wide shim between flat on shaft and flat on lever. Reinstall and tighten to 10-12 ft. lbs.

DESCRIPTION

DESCRIPTION: Torque converter and hydraulically controlled two-speed planetary gear type transmission similar in design to 1954-55 models. For detailed description, **see 1954-55 PowerFlite Transmission".**

OPERATION

OPERATION: Same as for 1954-55 PowerFlite Transmission.

LUBRICATION

1956-58 MODELS

►*TRANSMISSION FLUID LEVEL & CHECKING PROCEDURE CHANGE:* To avoid overfilling and trouble under high speed and high temperature operating conditions, it is recommended that the following checking procedure be used and that the recommended fluid level not be exceeded. *This supersedes previous recommendations.*

►*NOTE:* It is recommended that the fluid level be checked with transmission "Cold" (after being parked for a considerable time and before being driven several miles). If necessary to check transmission "Hot" (after car driven for several miles), observe the special hot fluid level given below.

Checking Fluid Level (Cold Transmission) - Run engine at idling speed with parking brake applied. Operate all push buttons in turn (leave in each position momentarily), then check fluid level with "N" (Neutral) button pushed in. Note level indicated on dipstick, add or remove oil as follows: **Level between "L" mark and ½" below "L" mark** - Do not add oil - this level is satisfactory. **Level below ½" below "L" mark** - Add oil to bring level up to between "L" mark and ½" below "L" mark. **Level above "L" mark** - Remove oil until level has been lowered to between "L" mark and ½" below "L" mark.

Checking Fluid Level (Hot Transmission) - Proceed as for cold check above. Add or remove oil in accordance with fluid level on dipstick as follows: **Level between "F" mark and ½" above "L" mark** - Do not add oil - this level is satisfactory. **Level below "L" mark** - Add oil to bring level up between the "L" mark and ½" above the "L" mark. **Level above "F" mark** - Remove oil until level is between "F" mark and ½" below "F" mark. *NOTE* - On cars with first type dipstick (1 5/8" between "F" and "L" marks), maintain level at ½" below "F" mark.

1959 MODELS

Checking Fluid Level: Check fluid level in transmission every 1000 miles with transmission at normal operating temperature. Apply parking brake and idle engine, then depress each button, returning to neutral after button is pushed in. With engine idling and transmission in neutral, check fluid level on dipstick. Fluid level should be between the "Add 1 Pint" mark and the

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

"Full" mark. If fluid level is below "Add 1 Pint" mark, add Automatic Transmission Fluid Type "A", Suffix "A" to bring level between the marks but never above the "Full" mark. If level is above "Full" mark, remove fluid to bring to proper level. *NOTE - When transmission and torque converter are drained and refilled, the lev l should be ¾" below the "Add 1 Pint" mark since the new fluid is not at op rating temperature.*

1960 MODELS

Ch cking Fluid Level: Check fluid level every 1000 miles with transmission at normal operating temperature. Apply parking brake and idle engine, then depress each button, returning to netural after button is pushed in. Fluid level should be at "F" mark or slightly below (never above "F" mark). Add or remove fluid as necessary.

►*NOTE: If fluid l vel is checked with transmission cold, fluid l v l should b at "L" (Low) mark or slightly b low.*

1956-60 MODELS

Draining & R filling: Drain transmission every 10,000 miles (supersedes previous recommendation of every 20,000 miles). Remove oil filler tube to drain transmission, then remove converter access plate and drain converter. Add five quarts of oil through oil filler tube, then start engine and add approximately three (Chrysler, DeSoto, Dodge), four (Plymouth) more quarts. Stop engine and completely fill transmission by following procedure for checking fluid level. See "Checking Fluid Level" for proper model (above).

R c mmended Fluid: Automatic Transmission Fluid Type "A" (Suffix "A").

Capacity: See following table. *NOTE - The following capaciti s are appr ximat . Total fluid required should b d termined by measuring with dipstick. See "Checking Fluid L v l" above.*

	Capacity (Quarts)				
M d l	1956	1957	1958	1959	1960
Chrysler (Exc. C-71)	11				
Chrysler (C-71)	10.2				
DeSoto	10.2	10	10	10	11
Dodge	10	10	10	10	11.5
Dodge Dart					10
Plymouth	10	10	10	10	10

LINKAGE ADJUSTMENT

►*THROTTLE LINKAGE ADJUSTMENT NOTE: See "Carbur tor" on car mod l pages.*

►*PUSH BUTTON CONTROL ASSEMBLY PRODUCTION CHANGE: Two typ s of control units have been used in production. S e "Push Button Control Assembly Production Chang " above.*

Manual Control Cable Adjustment: Remove neutral safety starting switch from side of transmission. Loosen adjustable mounting bracket capscrew and move cable and bracket assembly (manually) as required, to position the manual valve lever in neutral position. Hold the "N" (Neutral) button tightly in at full travel (the neutral starting switch cam should then be practically centered in neutral starting switch mounting hole). Use a free fitting flat-faced shaft inserted through the neutral mounting switch hole, and apply very light pressure against the manual valve lever to maintain the neutral detent position of lever. *(NOTE* - If tool is not available, lever may be held by finger pressure). Carefully move cable assembly "in" and "out" **without moving** the manual lever, to determine total free-play travel of cable. Locate the cable midway in the free-play range, release pressure against the manual lever and tighten mounting bracket securely. *Do not allow cable to move when tightening the bracket.* Install neutral starting switch and check transmission fluid level.

POWERFLITE "PUSH BUTTON" CONTROL ASSY. (FIRST TYPE SHOWN)

Throttle Pressure Adjustment: With throttle linkage properly adjusted and tachometer attached to engine, start engine and adjust idle speed to 475-500 RPM (with transmission in "N" and hand brake set). Stop engine and raise car on a hoist, then remove throttle pressure take-off plug located between reverse and kickdown servos on right side of transmission case. Connect Gauge, Tool C-3292, then start engine and push in the "D" (Drive) button on instrument panel. Engine speed will drop 50 RPM and pressure reading on gauge should be 13-15 lbs. (Exc. early 1958 models - See "Throttle Valve Production Change" above); 15-17 (Early 1958 models with first type throttle valve and spring). If pressure is not within specifications, remove throttle valve adjusting screw access hole plug (approximately 1 quart of fluid will drain out) and insert Adjusting Screw Wrench, Tool C-3279. Adjust pressure as necessary. *NOTE - Turn screw OUT to increase pressure and IN to decrease pressure.* Replace throttle valve adjusting screw access hole plug and tighten to 25 ft. lbs. Recheck throttle pressure. Move accelerator pedal very slowly. If throttle pressure and throttle linkage properly adjusted, pressure will rise 6-8 lbs. the instant engine RPM is increased. *NOTE - Do not use throttle rod when making this check; instead use accelerator pedal lever located on under side of floor pan.* Stop engine and remove oil pressure gauge and install plug. Tighten to 120 inch pounds. If necessary, replace fluid that drained out.

N utral Start r Switch Adjustm nt (1956-57): *NOTE - See "1956 Neutral Starter Switch Production Chang " above.* The early type switch can be adjusted by using an extra washer, Part No. 1113113, and reducing its thickness as required to secure proper switch contact. On later type switches (having an "O" ring seal and dished washer) attach an electrical contact indicator light to switch outer terminal and to transmission case, tighten switch until initial electrical contact is made, then tighten switch an additional 1/3 to 1/2 turn.

Neutral Starter Switch Adjustment (1958-60): Install mounting washer on switch so that concave side is away from switch, then place rubber "O" ring sealon switch and install switch in transmission case. Turn switch in until washer contacts case, then tighten switch an extra 1/3 to 1/2 turn. Connect wire and recheck switch operation.

BAND ADJUSTMENT

BAND ADJUSTMENT: *Kick-down (front) band can be adjusted externally. Reverse (rear) band adjustment requires removal of transmission case oil pan.*

Kickdown (Front) Band: Working from underneath car, loosen kickdown band adjusting screw locknut (located on left side of transmission case). Check freeness of adjusting screw in transmission case. If free, use inch-pound torque wrench, Tool C-3380 and tighten adjusting screw to 72 inch pounds. *NOTE - If Extension, Tool C-3583, used with torque wrench, tighten adjusting screw to 40-43 inch pound reading on torque wrench.* Use a reference mark of chalk or colored pencil on a corner of adjusting screw square and the transmission case. Using extreme care, back adjusting screw out **2¾ turns** (Exc. 1956 Dodge & 1956-59 Plymouth); **3 turns** (1956 Dodge & 1956-59 Plymouth). Hold adjusting screw with a wrench and tighten locknut.

Reverse (Rear) Band: Drain transmission and remove oil pan, then loosen band adjusting screw locknut and tighten adjusting screw to 20-25 inch pounds. Mark a reference point and back off adjusting screw **10 turns** (1956 & Early 1957 with first type servo piston - *Se "1957 PowerFlite Reverse Servo Piston Production Change" above);* **12 turns** (Later 1957-60 models). Hold adjusting screw and tighten locknut to 30-35 ft. lbs.

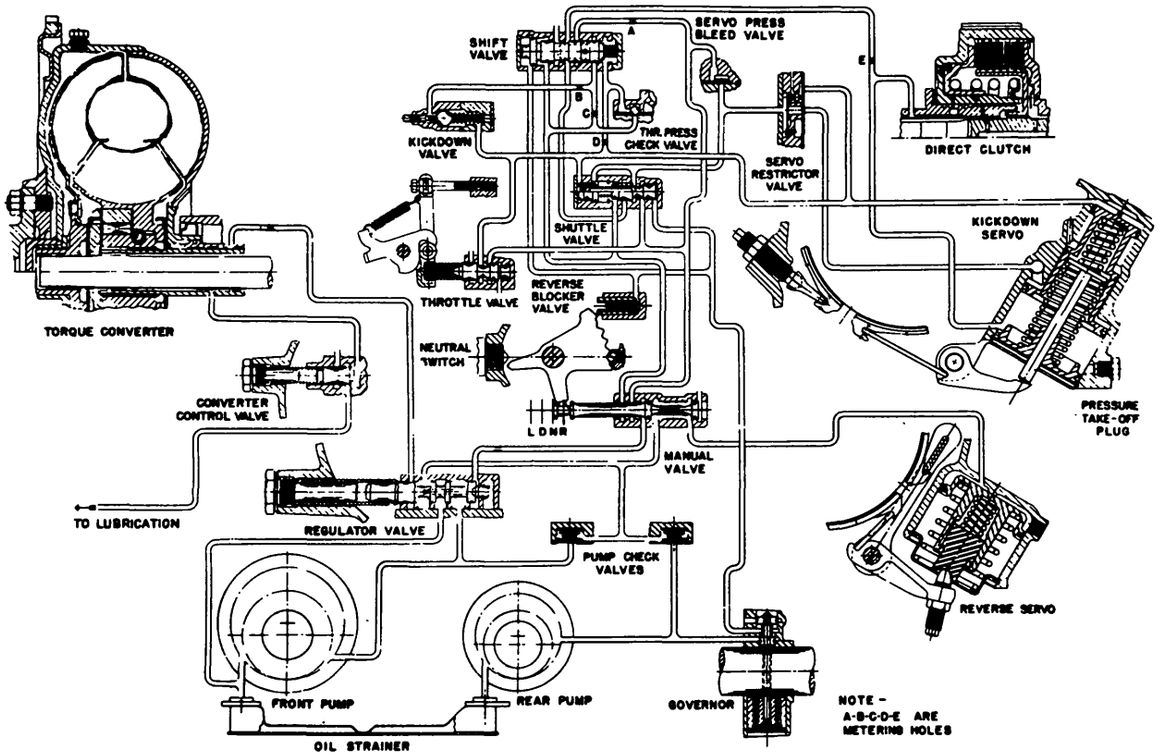
ROAD TESTING TRANSMISSION: If transmission operation not satisfactory, following complete procedure is recommended to check performance and diagnose trouble.

1) Move selector push buttons through their positions. Check for binding or hanging, or insufficient travel. Do not operate engine in reverse at wide open throttle.

2) Attach an electric tachometer to engine. Push in "D" (Drive) selector button. Check speed and smoothness of engagement. Apply both hand brake and foot brake and check for band slippage at wide open throttle *(CAUTION - D n t h ld thr ttle wide open more than a few s conds).* See "Stall Speed Table" below. Check for kickdown band adjustment before proceeding with road test.

3) Accelerate engine at very light throttle. The transmission should upshift at speeds given in "Shift Speed Table" above. Check quality of shift.

4) Slow car to 15 MPH, and go quickly to wide open throttle (without going into kickdown). Check for possible clutch slippage. The transmission should not downshift at this time.



5) Make a kickdown at 15 to 20 MPH and check quality of shift. Release accelerator to approximately half throttle so that transmission upshifts at 25 to 30 MPH. Check quality of shift.

6) Make a kickdown, between kickdown limits as indicated in "Shift Speed Table" above, and check the quality of shift. Release accelerator to closed throttle and check quality of "lift foot" shift.

7) Make a kickdown at 45 MPH and check quality of shift. Accelerate in kickdown, at wide open throttle, until transmission upshifts. The shift should occur at speeds indicated in "Shift Speed Table" above. Check quality of shift.

8) Slow down to 40 to 50 MPH and push in "L" (Low) selector button. The transmission should downshift. Push in "D" (Drive) button at approximately 20 MPH. The transmission will upshift. Coast to a stop. The transmission should downshift as indicated in "Shift Speed Table" above. Check for smoothness of shifts.

STALL TEST: Use an accurate tachometer to check engine speed. With engine idling, push in the "D" (Drive) selector button and note smoothness of shift. Set hand brake firmly and apply foot brakes to hold car. Accelerate engine to wide open throttle and check engine speed. Speed in excess of maximum RPM as indicated below may be caused by band slippage. *Do not hold engine at wide open throttle more than a few seconds.*

POWERFLITE TRANSMISSION HYDRAULIC CIRCUITS

Stall Speed Test ℄

Car Model	Engine RPM
1956 Chrysler C-71 (With Power Pack)	1920-2020
1956 Chrysler C-71 (Std.) & C-72	1580-1680

1956 Plymouth V8 (187 HP)	1640-1740
1957 Plymouth 6 Cyl.	1370
1957 Plymouth V8 (277" Engine)	1670
1957 Plymouth V8 (310" Engine)	1720
1958-59 Plymouth	1500
1960 Plymouth	1400-1500

℄ — Wide open throttle, "D" (Drive) selector button pushed in.

► *CAUTION — When making stall test, do not hold throttle wide open for more than a few seconds.* If engine speed excessive and is not corrected by band adjustment, make additional checks as follows: Check for incorrect manual control cable adjustment; leakage at valve body mating surfaces; defective throttle valve; defective shuttle valve or valve body and cover plug; defective kickdown servo parts.

HYDRAULIC PRESSURE TESTS: *CAUTION* - Pressure differences from 15 lbs. to 250 lbs. will be found in making following tests and correct pressure gauge must be used.

Gauge No. C-3292 (100 lbs.) — Use for throttle pressure, governor pressure, and lubrication pressure checks.

Gauge No. C-3293 (300 lbs.) — Use for line pressure check.

Line Pressure: Remove 1/8" pipe plug from line pressure take-off hole (front left side of transmission case), install C-3293 (300 lb.) pressure gauge at this point. Check reverse oil pressure first (brakes off), then apply brakes to hold car and check the other points. Run engine at speed indicated in table below, check line pressure for each selector button position.

1956 Line Pressure

Selector Button Engaged	Eng. RPM	Pressure
"R"	1600 ℄	225-275 lbs.
"N"	800	85-95 lbs.
"D"	800	85-95 lbs.
"L"	800	85-95 lbs.

℄ — 1400 RPM on Dodge models.

1957-60 Line Pressure

Selector Button Engaged	Eng. RPM	Pressur
"R"	1400	225-275 lbs.
"N"	800	85-95 lbs.
"D"	800	85-95 lbs.
"L"	800	85-95 lbs.

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

►*NOTE:* If line pressure not correct, check for: Low oil level or clogged strainer; defective regulator valve and spring; manual valve and lever; throttle valve, cam and spring; oil leakage at valve body, or regulator body mating surfaces; defective kickdown piston and related parts; worn front pump or defective front pump drive sleeve or pinion.

Thr ttle Pressure: Remove 1/8" pipe plug from throttle pressure take-off hole (right center of transmission case between the servos), install C-3292 (100 lb.) gauge at this point. Apply brakes to hold car, push in the "D" (Drive) selector button, run engine at speed indicated in table below and note throttle pressure at each speed.

1956-60 Throttle Pressure
①(Except Early 1958 Models)

Thr ttle Opening	Eng. RPM	Pressure
Closed	Idle	13-15 lbs.
Wide Open	②	80-90 lbs.

① Early 1958 Throttle Pressure

Throttle Opening	Eng. RPM	Pressure
Closed	Idle	15-17 lbs.
Wide Open	②	80-90 lbs.

① - See "PowerFlite Transmission Throttle Valve Production Change" above.

② - See "Stall Speed Test" above for engine RPM of various models.

►*CAUTION: When making the above test, do not hold throttle wide open for more than a few seconds. If engin speed exceeds maximum as indicated in "Stall Speed Table" above (indicating band slippage), check the cause in the same manner as for "Stall Test".*

►*NOTE:* If throttle pressure not correct, check line pressure (above) and also check the following points: Incorrect throttle linkage adjustment; leakage at valve body mating surfaces; defective throttle valve, cam & spring; defective throttle pressure check ball or kickdown valve ball and rod; defective kickdown piston or related parts.

Gov rnor Pressure: Remove 1/8" pipe plug from governor pressure take-off hole on lower left side of output shaft support (plate between transmission case and extension housing), install C-3292 (100 lb.) gauge at this point. Support car securely with rear wheels off floor so that they are free to turn, push in the "D" (Drive) selector button and run engine at speed indicated (as noted on speedometer). Note governor pressure in each speed range.

①G vern r Pressur

1960 Plymouth (All)	13-15	24-32	51-60

① - Governor pressure at indicated MPH.

►*NOTE:* If governor pressure not correct, check for leakage at valve body mating surfaces or output shaft support gaskets; defective governor assembly; or defective rear pump.

Lubrication Pressure: Check only when there is reason to believe that it is incorrect. Remove pipe plug fitting at upper left side of output shaft support (Exc. 1956 Chrysler C-70, C-72, C-73 & 1956 DeSoto S-24) and install a 1/8" flared tube c nnector. On 1956 Chrysler C-70, C-71, C-73 & 1956 DeSoto S-24, disconnect oil cooler line at this point and install 1/8" flared tube connector. Connect gauge C-3292. With engine running at 800 RPM, transmission in "N" (Neutral) position, lubrication pressure should be 35-50 lbs.

►*NOTE:* If lubrication pressure is not correct, check for leakage at regulator body mating surfaces or at output shaft support gasket; defective converter control valve, defective front pump drive sleeve; defective reaction shaft bore; defective input shaft seal rings; plugged lubrication holes.

Clutch Pressure: Remove the 1/8" pipe plug fitting from pressure take-off hole tapped in kickdown servo (clutch pressure take-off plug on forward right hand side of transmission case) and install gauge C-3292. With rear wheels free to turn, accelerate the engine slowly until an upshift occurs. During the upshift, the pressure gauge attached to the kickdown servo should show a very rapid rise from 0 to final clutch or line pressure (see "Line Pressure Table" above). This rise should not take more than 1½-2 seconds. With engine speed not less than 650 RPM (trans. upshifted), the direct clutch pressure should not read lower than 10 lbs. below line pressure. Should a slow rise in clutch pressure be observed or a clutch pressure of more than 10 lbs. lower than line pressure be obtained, it is an indication of abnormal leakage.

►*NOTE* – If clutch pressure not correct, check oil level; throttle linkage adjustment; converter control valve; valve body mating surfaces; throttle valve, cam and spring; kickdown piston and guide; regulator valve body mating surfaces; front pump drive sleeve; clutch retainer bushing and reaction shaft seal rings; clutch discs and plates; clutch piston, seal rings and eheck valve ball.

►*1956 POWERFLITE DIFFICULT SHIFTING TO REVERSE RANGE CORRECTION:* Remove valve body and inspect reverse lockout valve, valve port and spring. Valve and valve ports must be free burrs, and spring action must be checked to make sure it does not take a set when compressed. If spring is faulty, replace with spring, Part No. 1672079. Check operation of governor valve (if valve is not operating freely, it may apply reverse blocker valve when in neutral and prevent manual shift lever from going into reverse). With engine off, attempt to place transmission in reverse through use of push buttons. If transmission will go into reverse with the engine off, it is evident that a "no reverse" with engine running is due to a sticking governor valve holding the blocker valve open. Remove governor pressure checking plug and try to free-up the governor by applying short blasts of air into governor circuit. If governor cannot be freed up in this manner, remove governor assembly and clean it. Inspect governor support seal rings for score or gap (ring must have no gap when compressed). The governor oil passage in rear pump housing must be located between the wear pattern caused by governor support seal rings (the forward seal ring prevents line pressure entering governor outlet passage located between the two seal rings). Check governor for looseness, excessive output shaft endplay, or improperly drilled rear pump housing and correct as necessary. Check to see that seal rings seal on each side of governor pressure outlet passage in pump housing. If not, measure from center line of governor pressure hole-to-inside face of pump housing. If the specification of .443" ± 1/32" are exceeded, replace the pump housing. Check governor body pressure relief holes for obstructions. Make sure all assemblies are clean before reassembly.

TROUBLE SHOOTING & DIAGNOSIS

EXCESSIVE SLIPPAGE:

All Ranges—Inspect oil level. Adjust gearshift linkage. Check oil pressure; if low, inspect regulator valve and torque converter control valve for sticking. Inspect valve body in transmission case mating surfaces for evidence of oil leakage.

Kickdown—Readjust throttle linkage and kickdown band. Inspect valve body to transmission case mating surfaces for evidence of oil leakage. Check operation of throttle valve and note wear of valve bore and cam. Check spring. Check valve body end cover for oil leakage. Check shuttle valve for free movement. Inspect kickdown piston and guide for binding. Inspect spring. Inspect band lining for wear and band lever for free movement.

Kickdown (Over 25 MPH)—Inspect valve body end cover for oil leakage. Inspect shuttle valve and plug for free movement. Inspect spring.

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

Hill Climbing—Insufficient oil will result in low pressures to kickdown servo or direct clutch if oil level is low.

Direct—Inspect valve body to transmission case mating surfaces for evidence of oil pressure leakage. Check kickdown piston for binding. Check shaft seal rings and clutch retainer bushing for wear. Check clutch discs, piston and clutch check valve.

Reverse—Check reverse band adjustment. Inspect transmission case to valve body mating surfaces for evidence of oil pressure leakage. Inspect reverse servo assembly for wear or binding. Inspect reverse lever and linkage for free movement.

SHIFT PATTERN:

No Upshift—Check oil level and gearshift linkage adjustment. Check governor and throttle pressure. If there is no pressure rise when accelerating engine in direct drive, governor valve may be stuck closed. Check valve body to transmission case for parallelism. Check manual valve and lever for correct detent engagement. Check shift valve for free operation and shift valve spring for breakage. Check kickdown piston assembly. Check rear pump drive pinion. Drive pinion ball may be cracked or broken, permitting pinion gear to slip. Inspect clutch ball check for proper operation. Ball check valve must operate freely and seat properly.

No Shift in "D" (Drive) Range and an Upshift In Low Range—The cause is the governor valve sticking open. This can be verified by checking governor pressure (see "Governor Pressure Test" above). If governor pressure exceeds the pressures indicated in table, governor valve is possibly stuck and in most cases can be corrected in the following manner. Clean off area around governor pressure takeoff plug and remove plug. Cover oil filler tube with a cloth or plug and hold firmly to prevent air from forcing transmission oil out through filler tube. Screw a piece of ⅛" pipe into hole to help direct air into unit. Apply clean filtered air to pipe in short blasts, tapping parking brake drum at same time with a rubber hammer just enough to jar governor. After applying air pressure, recheck governor pressure and see if valve has been freed up. In cases where governor pressure is still to high, it will be necessary to remove transmission extension case for further inspection.

Low Upshift Pattern—Readjust throttle linkage. Check governor pressure. Governor valve may be binding or sticking. Inspect the rear pump assembly. Check valve body to transmission case for parallelism. Check operation of throttle valve and inspect cam and spring. Check shift valve for free operation and spring for breakage.

Low Upshift Pattern at Heavy Throttle—Inspect regulator valve, throttle valve, and governor for burrs or dirt which may cause binding or sticking. Inspect the regulator spring.

High Upshift Pattern—Readjust throttle linkage and check both throttle and governor pressures. Adjust throttle pressure if necessary. If throttle pressure does not rise according to speeds on chart (see "Throttle Pressure" above), throttle valve may be sticking. Inspect for dirt or burrs. Inspect throttle cam for wear. Check valve body to transmission case for parallelism. Check shift valve spring. If governor pressure does not correspond to pressures indicated in "Governor Pressure" table above, remove governor and inspect valve for sticking. Check rear pump gears for wear, broken teeth or excessive clearance. Inspect pump drive pinion ball.

All Upshifts Below 14 MPH—Inspect throttle valve, cam and spring. Check throttle pressure check ball. Check governor valve for sticking.

Erratic Shifting—Check oil level. Inspect valve body to transmission case for parallelism. Check action of shift valve. Inspect governor support gaskets for oil leakage.

No Downshift—Check governor pressure. High initial pressure indicates valve is stuck open. Remove governor and inspect. Inspect shift valve action, check spring.

Low Downshift Speed—Governor valve is stuck open. Remove and clean and check for burrs and dirt.

High Downshift Speed—Readjust gearshift linkage. Inspect valve body to transmission case for parallelism. Inspect manual valve and lever. Inspect kickdown valve and ball.

No Kickdown—Adjust throttle linkage. Inspect valve body to transmission case for parallelism. Inspect throttle valve, cam and spring. Also inspect kickdown valve and shift valve components.

Low Kickdown Limit—Check governor pressure Governor valve may be sticking due to dirt. Inspect regulator valve and spring for proper operation. Inspect rear pump gears and drive pinion ball. Check valve body cover plate for parallelism.

SHIFT QUALITY:

Harsh Shift from Neutral to Reverse—Adjust engine idle speed. Readjust rear band. Inspect condition of the reverse band, strut and linkage. Inspect the reverse servo piston, spring valve and rings.

Harsh Shift from Neutral to Drive—Adjust engine idle speed Adjust throttle linkage. Inspect kickdown servo pistons, springs, guide, rod and piston rings.

Delayed Shift from Neutral to Drive—Adjust kickdown band. Inspect condition of band, strut, lever and lever shaft.

Excessive Engine Speed Increase on Upshifts—Check oil level and adjust throttle linkage. Inspect regulator valve and spring and check operation of valve in regulator body. Check valve body mating surface for parallelism. Inspect throttle valve, cam and spring. Check operation of valve in valve body. Inspect kickdown piston components. Check mating surfaces of regulator valve body and transmission for parallelism. Inspect reaction shaft seal ring for deterioration. Inspect input shaft oil seal rings for wear or breakage and condition of reaction shaft bore. Inspect clutch retainer bronze bushing. If worn below bronze surface, replace retainer. Inspect condition of reaction shaft oil seal rings for wear or broken ends. Inspect condition of clutch plate and condition of friction material on seal ring. Check clutch check valve ball.

Excessive Engine Speed Increase on Upshifts at Light Throttle—Check line pressure. Inspect front oil pump gears for wear and excessive clearance.

Harsh Upshift—Adjust throttle linkage. Inspect regulator valve and spring. Check for sticking shuttle valve. Check valve body mating surfaces for parallelism. Inspect throttle valve, cam and spring. Inspect kickdown piston components. Check regulator valve body mating surfaces for parallelism. Inspect direct clutch spring, spring retainer, and snap ring.

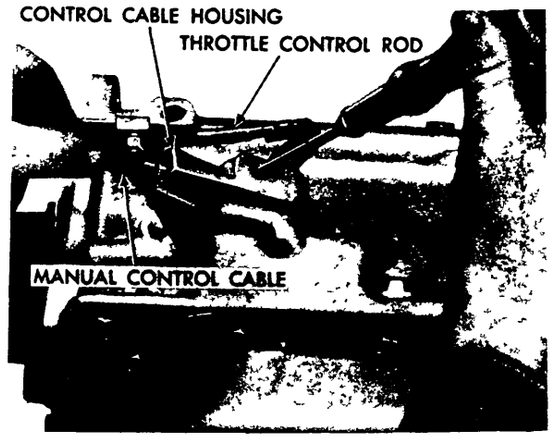
Harsh Lift Foot Shift—Adjust throttle linkage. Check valve body mating surface. Check operation of throttle valve. Inspect valve, valve bore, cam and spring. Inspect servo pressure bleed valve for dirt. Check operation of shuttle valve. Inspect shuttle valve, plug, inner and outer springs, and guide pin.

Excessive Engine Speed Increase on Downshift at Part Throttle—Check oil level and adjust throttle and gearshift linkage. Check valve body mating surface. Check operation of manual valve and valve lever. Inspect servo restrictor valve and operating plug. Check plug for free operation. Check valve spring for distortion or looseness.

Harsh Downshift—Adjust engine idle speed and throttle linkage. Inspect valve body mating surface. Inspect throttle valve, cam and spring for proper operation. Inspect for dirt, burrs or wear, or breakage. Inspect servo restrictor valve for proper operation. Inspect clutch plates and disc friction material. Inspect the piston for wear or scor-

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)



ing. Check seal for wear or deterioration which would result in leakage. Inspect thrust washers for excessive wear.

Excessive Increase in Engine Speed on Kickdown—Readjust kickdown band. Check regulator valve and spring for proper operation. Inspect for dirt, wear, or breakage. Check valve body mating surface for nicks, burrs and trueness, which would cause leakage. Check operation of servo restrictor valve and shuttle valve Inspect valve and plug for dirt, burrs or wear. Inspect all parts of kickdown piston assembly. Inspect piston rings for excessive wear or broken ends. Check governor valve for wear, dirt, binding or sticking. Inspect rear pump gears for excessive wear or broken teeth. Check pump clearance, drive pinion gear and pinion ball.

Harsh Kickdown—Adjust kickdown band. Inspect regulator valve and spring. Inspect for dirt, burrs or breakage. Inspect servo pressure bleed valve for dirt. Check operation of shuttle valve. Check valve and plug for burrs, dirt or excessive wear. Inspect all parts of kickdown piston assembly. Inspect piston rings for scoring, wear or broken ends. Inspect regulator valve body mating surface for nicks, burrs and trueness which would cause leakage. Inspect reaction shaft neoprene seal for deterioration. Inspect governor valve for free operation. Check for dirt which would cause sticking. Inspect rear pump gears for excessive clearance, worn or chipped teeth. Inspect drive pinion gear and drive pinion ball. Inspect the input shaft seal rings for excessive wear or broken ends, and reaction shaft bore for scoring. Inspect all parts of the direct clutch assembly.

OIL PRESSURE:

No Governor Pressure—Governor valve may be stuck in closed position due to dirt. To free valve, apply a short spurt of high air pressure (90 lbs) to governor pressure take-off hole and at same time tap transmission extension housing with a rubber mallet Before applying air pressure, cover filler tube with a cloth. In addition, drain two or three quarts of oil from transmission oil pan. After air is applied, reinstall governor pressure take-off plug and run transmission in Reverse a few seconds. Recheck governor pressure. This corrective procedure may not be permanent. If valve becomes stuck again, remove governor for servicing. If pressures do not correspond to those indicated in "Governor Pressure" table above, the governor may need service. However, before servicing governor, check the other points in the transmission that could cause low pressure as follows· Check the valve body mating surface for trueness, nicks or burrs. These could cause oil leakage. Check both output shaft support gaskets for evidence of internal leakage. Check operation of governor valve and inspect for foreign matter. Check the rear pump gears for broken teeth, wear, and excessive clearance. Check the mating surface of output shaft for trueness, burrs or nicks.

TRANSMISSION GEARSHIFT CONTROL (CABLE RELEASING PROCEDURE)

High Initial Governor Pressure—High governor pressure at low engine speeds is due to the governor valve being stuck in the open position, usually caused by dirt *(see "No Governor Pressure" above)*, for clearing with air pressure.

Line Pressure—If line pressure does not correspond to pressures indicated in "Line Pressure" table above, it will be necessary to investigate and make the following adjustments or corrections: Check transmission oil level. Inspect regulator valve for free operation, dirt or burrs, and condition of valve spring. Check valve body mating surface for trueness, nicks or burrs. Check operation of manual valve and lever. Inspect front pump gears for worn or chipped gears. Check clearance between gears and face of housing.

Throttle Pressure—If throttle pressures do not correspond to pressures indicated in "Throttle Pressure" table above, check line pressure and make the following adjustments and corrections: Adjust throttle linkage. Inspect operation and condition of regulator valve and spring. Check valve body mating surfaces for nicks, burrs and trueness. Check operation and condition of throttle valve, cam and spring. Check throttle pressure check valve ball for nicks and dirt. Inspect condition of kickdown rod and ball.

Direct Clutch Pressure—Direct clutch pressure should be approximately 10 lbs. lower than line pressure with transmission upshifted and engine speed not lower than 650 RPM. If not, refer to "Excessive Engine Speed on Upshifts" above. A pressure drop between line pressure and direct clutch pressure as high as 25 lbs. may be due to broken or damaged seal rings in the direct clutch circuit. These are: three interlocking type input shaft seal rings; the direct clutch piston retainer seal ring, direct clutch piston neoprene seal ring, the neoprene reaction shaft seal ring, and the two interlocking type reaction shaft seal rings.

Lubrication Pressure—Lubrication pressure is checked at the upper left side of the output shaft support, Remove the ⅛" pipe plug and use 100 lbs., pressure gauge C-3292 to check pressure. Lubrication pressure should be 35 to 50 lbs. pressure with transmission in neutral and engine speed at fast idle. If pressure readings are incorrect, check line pressure and inspect torque converter control valve. Low pressures may be due to internal oil leakage at the following points: drive sleeve seal ring, regulator valve body mating surface, reaction shaft seal ring, output shaft support gaskets, input shaft seal rings, and reaction shaft bore. Low oil pressure may also be caused by plugged lubrication lines.

IMPROPER RESPONSE TO GEARSHIFT SELECTOR LEVER POSITIONS:

Moves Forward in "N" (Neutral)—Adjust gearshift linkage. Adjust kickdown band. Inspect manual valve lever assembly. Check valve body mating surface for nicks, burrs and trueness which would cause leakage. Check operation of manual valve. Inspect all parts of kickdown piston. Check regulator body mating surface for nicks, burrs and trueness. Check clutch discs and plates for warpage which would cause dragging. Inspect clutch ball check.

Car Moves Forward in "N" (Neutral) at High Engine Speed—Clutch check valve ball bleed hole may be plugged causing centrifugal oil pressure to partially engage the direct clutch. A slight surge which is not continuous is normal.

Car Moves Backward in "N" (Neutral)—Readjust gearshift linkage and inspect manual valve and valve lever for proper engagement. Adjust reverse band, levers, strut, and shaft. Check for binding, dirt, excessive wear.

MISCELLANEOUS DIAGNOSIS PROCEDURES:

Starter Will Not Energize—Adjust gearshift linkage. Test neutral starter switch. Inspect manual valve lever for proper engagement.

Hard Shifting Into "N" (Neutral)—Check operation of neutral starter switch and inspect manual valve lever.

Hard Shifting Into "R" (Reverse)—Check operation of backup light switch and manual valve lever.

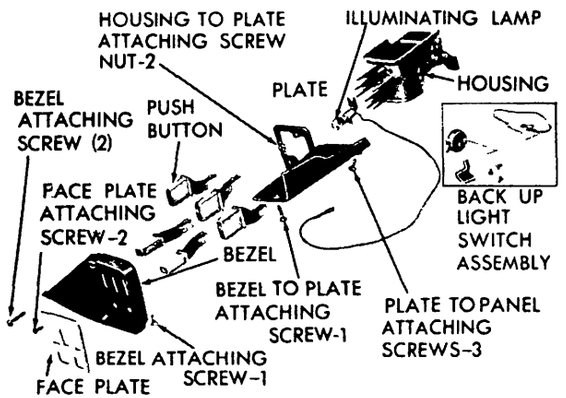
Oil Foams From Filler Tube—Check fluid level in transmission. Inspect transmission breather vent.

GEARSHIFT CONTROL UNIT REMOVAL & INSTALLATION

MANUAL CABLE ADJUSTMENT: *Se "Manual Cabl Adjustm nt" above.*

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)



►*1956 PUSHBUTTON CONTROL ASSEMBLY PRODUCTION CHANGE: Two typ s used in production, see "Changes, Cautions, Corr ctions" above.*

1956-59 MODELS

CABLE ASSEMBLY: R m val (Transmission End) – Drain transmission fluid and remove oil pan. Remove neutral safety switch to provide access to cable lock spring and remove cable bracket and screw. Insert screwdriver through neutral safety switch hole and push gently against vertical projecting portion of cable lock spring and pull outward on cable. *(CAUTION – Move spring only a suffici nt amount to permit removal of cable as undu pressure will dislocate spring).*

Installati n: (Transmissi n End) – Move manual valve lever into reverse position which will place the cable adapter in close proximity with cable entrance hole in transmission case. Push in the "L" button on transmission control. Place "O" ring seal on cable ferrule *(NOTE –* Inspect "O" ring seal for cuts, abrasions, brittleness or cracking. If any of these conditions are present, replace "O" ring seal. Hold cable parallel to hole centerline in transmission case and push control cable in until spring lock engages groove in cable end. Position cable bracket and install bracket capscrew. Measure and adjust cable free play (See "Free Play Adjustment" below), being careful not to move manual lever *(NOTE –* Rubber sheath on cable must be pressed onto cable ferrule in order to prevent any possible leakage of oil at this point. On later model cable assemblies, the ferrule will be double grooved and the rubber sheath will be held to the ferrule by the crimped connector). Tighten cable bracket screw. Operate push buttons to check cable adjustment. Adjust as necessary *(CAUTION –* Make sure cable housing is not forced in or out during tightening procedure as backlash will be disturbed). Replace neutral safety switch and transmission oil pan. Refill transmission to correct level using Automatic Transmission Fluid Type "A".

Cabl Backlash Adjustm nt: *See Manual Control Linkage Adjustm nt under LINKAGE ADJUSTMENT.*

PUSHBUTTON CONTROL ASSEMBLY (LATER TYPE SHOWN)

1960 MODELS

CABLE ASSEMBLY: R m val (Transmissi n End) - Push in "R" (Reverse) button, then remove neutral safety starter switch from transmission case. *NOTE - Approximately one quart of oil will drain out.* Loosen cable-to-transmission adjustable mounting bracket screw, then place a screwdriver through neutral starting switch hole and push against cable lock spring. Withdraw cable assembly from case. Check cable ferrule "O" ring for roughness, shredding or deterioration and replace if necessary. Make sure slot in bracket fits just freely into ferrule groove to full depth of slot.

Installation: Push in "L" (Low) pushbutton and then place transmission manual valve lever in reverse detent by moving neutral switch contact part of lever full travel toward rear using a screwdriver inserted in neutral starting switch hole. With "L" (Low) button held tightly in (full travel), insert cable assembly into case engaging cable ferrule groove with lock spring in cable adapter. Make sure groove in cable properly engages lock spring. Replace adjustable mounting bracket and tighten capscrew finger tight. Refill transmission and adjust manual cable (see above).

1956-57 MODELS

PUSH BUTTON CONTROL UNIT: (Removal) – Remove three bezel retaining screws (one screw is located on underside of unit receiver), and remove bezel and push buttons. Remove the two hex head nuts and lockwashers holding push button control unit to instrument panel. Pull push button control unit from rear of instrument panel, down and toward front of car. Remove the two screws holding cable assembly bracket to control unit. Remove hairpin clip securing cable end to actuator bar and remove cable. (After cable is removed from transmission, see "Cable Assembly" above, pull cable through rubber grommet, or remove grommet on dash panel).

Installation: Reverse removal operations and adjust cable free play.

Control Unit Light Bulb Replacement: Remove the three bezel retaining screws (one screw is located on underside of unit receiver) and remove bezel and "D" push button. Install light bulb, replace push button, reinstall bezel and test operation of unit.

1958-59 MODELS

PUSHBUTTON CONTROL UNIT: Removal - Removal procedures are different for the various models as noted below.

DeSoto - Disconnect one battery cable, then at rear of instrument panel, disconnect back-up light switch (if car is so equipped) and control unit lamp leads. Remove two small cross-head screws from face plate to expose two of the bezel retaining screws (third screw is at bottom of bezel). Remove bezel, then remove cross-head screws retaining gearshift housing and plate assembly to instrument panel. Pull plate and gearshift housing straight out and down from instrument panel until control cable and bracket are exposed. *CAUTION - If housing is quipp d with back-up light switch, us car to avoid damag t switch when r moving plat .* Remove two retaining nuts securing plate to housing and remove plate. Remove two screws holding cable assembly bracket to gearshift control housing. Remove hairpin clip securing cable to actuator, then remove cable from gearshift housing. If necessary to remove pushbuttons from slides, slightly spread fingers on slides and withdraw buttons.

Dodge - Remove back-up light switch and lamp lead wires, then remove four screws holding gearshift control housing and plate assembly to instrument panel (one screw at top front of plate, one screw at front edge of plate and two screws at bottom rear of plate). Partially pull plate and gearshift control housing assembly straight out and down from instrument panel. If housing is equipped with back-up light switch, use care when removing plate so as not to damage switch. Remove two retainer screws securing plate to housing, then carefully remove plate by pulling plate away from pushbuttons. Remove two screws holding cable assembly bracket to control housing. Remove hairpin clip securing cable end to actuator and remove cable from housing. To remove pushbuttons, spread fingers on slide and withdraw buttons.

Plymouth - Remove three bezel attaching screws, then remove bezel and pushbuttons. Remove two hex nuts holding pushbutton unit to instrument panel and remove pushbutton unit from rear of instrument panel. Remove cable bracket from pushbutton unit and cable from actuator bar.

Installation: Reverse removal operations and adjust cable freeplay.

Control Unit Bulb Replacement: Remove face plate, then remove as many pushbuttons as necessary and remove bulb.

1960 MODELS

PUSHBUTTON CONTROL UNIT: Removal (All Models) - Disconnect battery cable, then disconnect back-up light switch wire at pushbutton control and illuminating lamp leads at rear of instrument panel. Remove screws of pushbutton face plate and remove pushbuttons by pulling them off button slides. Remove lamp bulb. Remove control housing stud nuts and remove control and cable from rear of instrument panel. Remove clip attaching control cable to actuator and the screw holding cable bracket to control housing.

Installation: Insert end of cable on actuator and install clip, then place cable bracket on control unit and install screws securely. Carefully guide unit from rear of instrument panel and install nuts. Install lamp bulb and pushbuttons. Replace front plate, then connect back-up switch wires and illuminating lamp wires. Connect battery cable.

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

PARTS REM VAL & INSTALLATI N (TRANSMISSION IN CAR)

►***NOTE: Transmission must be removed from vehicle for the removal and replacement of parts other than those listed below.***

Oil Pan: Remove oil pan filler tube, drain transmission and remove oil pan attaching screws and oil pan. When installing pan, tighten screws evenly and torque to 12-17 ft. lbs.

Governor Servicing: ***NOTE—It is necessary to remove transmission extension to remove governor assembly. See "Transmission Overhaul" below for Extension Housing Removal, Governor Removal, Overhaul & Installation.***

Valve Body & Transfer Plate Assembly (Removal): Remove oil pan and disconnect throttle and manual control lever linkage from levers. Loosen throttle and manual control lever assembly locking screws. Slide throttle valve operating lever assembly off shaft and remove throttle valve camshaft felt retainer and felt. Slide manual valve lever assembly off shaft and remove valve lever shaft seal cover. Remove the two oil strainer support screws and washers and take the strainer assembly off valve body and plate assembly. Remove transfer plate screws and lock washers and remove valve body and transfer plate assembly. For overhaul. ***See "Valve Body Overhaul" below.***

Installation—Clean mating surfaces and check for burrs on both transmission case and valve body transfer plate. Place valve body and transfer plate assembly into position and install plate screws and lockwashers ***(CAUTION—The two 1⅝" screws go through transfer plate cover on valve body. The three 1⅛" are used in the other holes).*** Tighten evenly to 12-17 ft. lbs. torque. Make sure the two oil strainer tube seals are in position over oil strainer and place oil strainer assembly into position on transfer plate. ***(CAUTION—Check to see that oil tubes on strainer properly enter valve body).*** Install the two oil strainer support screws and torque to 12-17 ft. lbs. Place manual lever shaft seal cover over manual valve lever shaft and slide into position on transmission case. Install manual lever (arm side of lever against cover) on manual valve lever shaft, and tighten locking screw. Place throttle valve camshaft felt and retainer over throttle valve shaft. Install throttle valve lever assembly on throttle camshaft and tighten locking screw. Check operation of control by shifting into all positions. Check kickdown operation and manual lever contact on neutral safety and back-up light switches. Install oil pan and adjust throttle linkage and gearshift linkage.

Manual Control Valve Lever Shaft Oil Seal Removal & Installation: Remove oil pan, valve body and transfer plate assembly. Using a suitable brass drift, drive seal out of transmission case from below. To install, use tool C-3277. Start seal squarely into bore and tighten tool C-3277 until it is flush with the case. This properly positions seal. Install valve body and plate assembly and oil pan.

Kickdown Piston (Removal): Remove oil pan, valve body and transfer plate assembly. Loosen kickdown band adjusting screw locknut and back adjusting screw out sufficiently to permit kickdown band strut to be removed by compressing band ends. With kickdown band lever hanging down, install tool C-3289 on transmission case. Apply sufficient pressure on kickdown rod guide to permit easy removal of the snap ring. Loosen compressing portion of tool and remove piston rod guide, piston spring and kickdown piston rod assembly (the kickdown piston cushion spring will fall out of piston when rod assembly is removed). Using snap ring pliers, inserted inside of kickdown piston, remove piston from transmission case. ***See "Overhaul" below, for disassembly and inspection.***

Installation—Make sure the two interlocking seals are locked in position and all seals are coated with Lubriplate, then place kickdown piston into transmission case. With one hand apply pressure to piston and at the same time carefully compress bottom seal and push piston into case. ***(CAUTION***—After bottom seal has entered, piston will seem to hang at two different locations while being pushed into case. This is due to seals entering cylinder, do not use extreme force. If any rings should be broken when piston assembly is being installed, transmission will not operate properly.) Slide piston spring over kickdown piston rod assembly then balance piston cushion spring on rod assembly (Lubriplate may be used to help hold cushion spring in position on rod assembly), and install in piston. Holding it in this position, install kickdown piston rod guide assembly on piston rod assembly. Using tool C-3289, and extreme care, compress the kickdown piston spring to the point that piston guide seal slightly binds on transmission case. Work seal into position and gradually compress spring until seal enters case and snap ring can be installed. Install kickdown piston rod guide snap ring, making sure it is properly seated. Loosen compression portion of tool and remove tool from transmission case. With one end of band fit over adjusting screw, compress the other end sufficiently to install the kickdown band strut between kickdown band and band lever ***(CAUTION***—Make sure band strut slot engages with kickdown band strut pin in band end). Install valve body, plate assembly and oil pan. Adjust kickdown band.

Reverse Servo (Removal): Remove oil pan, valve body and transfer plate assembly. Loosen reverse servo adjusting screw locknut and back adjusting screw out sufficiently to permit reverse band strut to be removed by compressing band ends. Remove reverse servo piston sleeve. Mount tool C-3289 on transmission case and compress reverse piston spring retainer. Using a screwdriver, remove the reverse servo piston and valve assembly spring retainer snap ring and loosen compressing part of tool (Spring retainer may require guiding out of transmission case). Remove spring retainer, spring, reverse servo piston and valve assembly from transmission case. Using C-3229 pliers, remove the reverse servo piston valve spring snap ring, and remove spring and valve from piston. ***See "Overhaul" below, for disassembly and inspection.***

Installation—Place reverse servo piston valve and spring in reverse servo piston (shaft on valve protruding through hole in bottom of piston). Using snap ring pliers C-3229, install reverse servo piston valve spring snap ring, making sure it is properly seated. Coat reverse servo piston ring (neoprene) with Lubriplate. Insert reverse servo piston and valve assembly into transmission case in a cocked position, then by rotating piston, the ring will enter case without being damaged. Place reverse servo piston spring over piston and position spring retainer over spring. Using tool C-3289, compress spring sufficiently to install snap ring. Make sure retainer is correctly installed, and snap ring seated. Remove tool C-3289 from transmission case and install reverse servo piston sleeve. Make sure piston sleeve slides freely on piston by working it up and down. Hook one end of reverse band assembly in reverse link assembly, compress other end sufficiently to install reverse strut in slots of reverse band assembly and reverse band lever assembly. Adjust reverse band. Install valve body, transfer plate and oil pan.

Speedometer Pinion (Removal & Installation): Disconnect speedometer cable and housing from sleeve assembly on transmission, and remove speedometer pinion and sleeve. When installing sleeve and pinion assembly, torque it to 40-45 ft. lbs.

Neutral Safety and Back-Up Light Switch Removal & Installation Note: It is not necessary to drain transmission to remove these switches. A small amount of lubricant will drain from transmission when these switches are removed. When installing, tighten switches to 15-20 ft. lbs.

Transmission Output Shaft Rear Bearing Oil Seal (Removal): Disconnect the front universal joint and secure shaft to frame out of the way. Apply hand brake and remove propeller shaft flange nut and washers. Release hand brake and install puller C-452. Remove propeller shaft flange and drum assembly. Remove transmission support grease shield spring (small one). Remove brake support grease shield from extension housing ***(CAUTION—If screwdriver or sharp instrument used to remove shield, do not damage the neoprene sealing surface at bottom of shield).*** Install puller C-748 and remove rear bearing oil seal.

Installation—Install rear bearing oil seal with tool C-3205. Install brake support grease shield on extension housing ***(CAUTION—Indent on grease shield must match groove in housing for correct positioning. Install grease shield far enough on housing to permit installation of spring).*** Install brake support grease shield spring with opening in spring toward adjusting sleeve. Make sure spring is properly seated in groove. Make sure brake adjustment is backed off and install drum assembly (In some instances it may be necessary to use tool C-496 to press drum assembly on output shaft). Install propeller shaft flange washer, shakeproof washer and nut. Adjust hand brake. Apply hand brake and torque propeller shaft flange nut to 140-160 ft. lbs. Connect front universal joint.

Transmission Regulator Valve Assembly (R moval): Remove transmission regulator valve spring retainer, gasket, and spring. Using a mechanical retriever or a piece of welding rod inserted in end of valve, remove valve.

Installation—Place valve in position in valve body. Install regulator valve spring, gasket, and retainer and tighten to 45-50 ft. lbs. torque.

Torque Converter Control Valve Assembly (Removal): Remove control valve spring retainer, gasket, and spring. Using a mechanical retriever or a piece of welding rod inserted in end of valve, remove valve.

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

Installation—Reverse removal procedure

Oil Cooler (Removal): Drain radiator, remove battery and battery pan Remove lower radiator-to-cooler hose Remove inlet and outlet oil tubes. Remove oil cooler to water pump flange bolts

Installation—Clean mating flanges thoroughly and install new flange gasket Install cooler to water pump and tighten flange bolts Install inlet and outlet oil tubes Install lower radiator-to-cooler water hose Install battery and battery pan Refill radiator and start engine Check carefully for water and oil leaks

TRANSMISSION REMOVAL

REMOVAL: Drain transmission and torque converter, (see "Draining & Refilling" above). When fluid drained, replace drain plugs and tighten. *NOTE - If transmission oil pan is not equipped with a drain plug, remove filler tube connected at oil pan).* Disconnect oil pan filler tube from oil pan. Disconnect front universal joint and secure to frame. Remove hand brake adjusting screw cover plate and cable bolt from hand brake support. Disengage ball end of cable from operating lever and remove cable from brake support. Disconnect speedometer cable housing from drive pinion. Disconnect neutral starter switch and back-up light wires from switches *(NOTE* - To avoid damage to switches, remove from transmission before removing transmission from car). Disconnect throttle linkage from lever at transmission. Remove push button control cable (see "Gearshift Control Unit" above). Remove oil cooler lines (if so equipped). Remove nuts and lockwashers from rear engine mount. Install engine support fixture, C-3487. Adjust fixture to support weight of engine and raise engine slightly. Remove cross member to frame bolts and remove cross member, leaving engine support adapter attached to transmission. Work carefully when removing cross member to avoid damaging brake line. *(CAUTION* - When using fixture, Tool C-3487, do not lower engine more than three inches from floor pan to avoid moving the set position of water hose and other engine attachments). Remove two upper transmission case to converter housing screws and lockwashers and install guide studs, Tool C-3276. Remove two lower transmission case to converter housing screws and lockwashers. Slide transmission straight back to avoid damaging front pump drive sleeve, and remove from under car.

TRANSMISSION INSTALLATION

INSTALLATION: Install guide studs, Tool C-3276, in the two upper transmission case to converter housing bolt holes. Lubricate front oil pump drive sleeve ring and bearing surface with transmission fluid. Install drive sleeve in front pump housing (if not previously installed), making sure that driving lugs are properly engaged in front pump pinion gear. Note position of driving lugs on front pump drive sleeve, and position accordingly, to aid in proper engagement with torque converter when transmission is installed. Slide transmission over guide studs and into position. To avoid damage to front oil pump, the transmission must be properly aligned. Do not attempt to use transmission to converter housing bolts to bring transmission and converter housings together. If oil pump drive sleeve and input shaft have been properly aligned, transmission should slide easily into position. *(CAUTION - Do not force it into position).* Install two lower transmission case to converter housing bolts and lockwashers, but do not tighten. Remove guide studs and install two upper transmission case to converter housing bolts and lockwashers. Draw all bolts down evenly and tighten to 45-50 ft. lbs. Complete installation by reversing removal procedure.

TORQUE CONVERTER REMOVAL

1) With transmission removed, turn front wheels to extreme right and remove starter motor Remove the transmission case adapter screws and lockwashers and remove transmission from car Remove lower half of flywheel housing

►*NOTE*: If torque converter being removed because of excessive runout damage, check by using dial indicator on hub and mark the highest point of runout on both converter and crankshaft flange The reason for this is so it may be determined later if runout was caused by the converter or crankshaft

2) Using tool C-811, remove the eight torque converter stud nuts and lockwashers from crankshaft flange Remove torque converter from crankshaft

►*NOTE*—Check crankshaft flange runout Maximum is 002"

STARTER RING GEAR REPLACEMENT (REMOVAL): Support torque converter assembly in a vise and carefully remove staking lugs, retaining ring gear to torque converter, with a file *(CAUTION*—Be careful when supporting torque converter in vise to avoid distortion) Place torque converter on blocks of wood, and using a blunt chisel or drift, tap around ring gear until it comes off converter

Installation of Ring Gear—Remove burrs or raised spots on torque converter with a file, being careful not to remove more metal than is necessary Any of the following methods for expanding the ring gear can be used in the manner outlined

Oven—Set temperature at 150° and allow ring gear to remain for 15 to 20 minutes

Boiling Water—Place ring gear in shallow container, add water and heat for approximately two minutes

Flame—Place ring gear on a flat surface Using a medium size tip, direct a slow flame around inner rim of gear, being careful not to direct flame onto teeth of ring gear Place a few drops of water on face of gear at short intervals during heating process When gear is hot enough to boil the drops of water, installation of gear can be made

When gear properly expanded, proceed as follows: Place starter ring gear over flange surface of torque converter, making sure that rear face of gear contacts flange on torque converter evenly around the entire diameter Reweld ring gear to torque converter, *using extreme care to place as nearly as possible the same amount of metal in exactly the same locations as original assembly* This is necessary to maintain proper balance of the unit Place weld alternately on opposite sides of the converter to minimize distortion Clean thoroughly before installing in car

►*RING GEAR WELDING NOTE* Use a welding current of 200 amps and 5/32" Fleet-Weld No 27, or General Electric No W28 rod, or their equivalent

►*WELDING CAUTION*. To prevent burning through the torque converter, the arc should be directed at the intersection of gear and housing from an angle of approximately 45° from the face of the gear DO NOT GAS WELD.

TORQUE CONVERTER INSTALLATION

►*TORQUE CONVERTER HUB RUNOUT NOTE*: When torque converter assembly is removed for any reason from crankshaft drive flange, the converter assembly runout should be checked when reinstalled There are two methods for adjusting the hub runout *See "Torque Converter Hub Runout Adjustment"*

1) Inspect mating surfaces of torque converter and crankshaft flange for burrs and dirt Install torque converter on crankshaft flange Install eight torque converter stud nuts and draw down evenly and tighten Install lower half of flywheel housing and starter motor

2) Install transmission case adapter on flywheel housing and tighten to 25-30 ft lbs torque Install transmission (see above)

3) Fill transmission with Automatic Transmission Fluid (Type A) to "full" mark on dipstick This will take approximately 5 qts Run engine at idle speed in neutral for approximately two minutes, then add 8 qts of fluid to bring oil level to "full" mark on dipstick Allow engine to run until normal operating temperature is reached Set handbrake and shift selector lever through all ranges and return it to "N", recheck level and bring level to "full" mark.

TORQUE CONVERTER RUN-OUT ADJUSTMENT

Heat Method: ***(CAUTION—When using this method, extreme caution must be used to prevent burning the metal and causing irreparable damage. Sufficient heating of this unit, to cause the necessary drawing of metal required, is accomplished in just a few seconds. DO NOT OVERHEAT).*** Remove transmission, torque converter housing and dust shield. Mount Torque Converter Hub Alignment Indicator C-430 on adapter plate Rotate converter through 360° and mark high point on converter with chalk, then rotate converter to move the high point to the top Apply heat 180° from the high point at opposite side of converter shell at **high point of radius** Use a No 3 acetylene torch burner, moving the flames at all times in a circular motion about the size of a dime When the spot begins to change color remove the flame and quench the converter with a water soaked rag. Change rags several times (the more quickly converter is cooled, the greater the drawing on the metal). Before checking hub runout make certain that both sides of the converter are the same temperature If runout exceeds 004' at the same point, repeat operation. *(CAUTION*—It is possible to draw the metal excessively, thus causing runout at opposite side.

Shim Method: Determine hub runout in the same manner as for "Heat Method" above Loosen converter drive flange nuts sufficiently to insert shims of proper thickness 180° from indicated high point. The thickness of shims used should equal half the total indicator reading, shim thickness not exceeding 008" New shims are furnished in the following sizes Part No 1610442 (002"), 1610443 (003), No 1610444 (005")

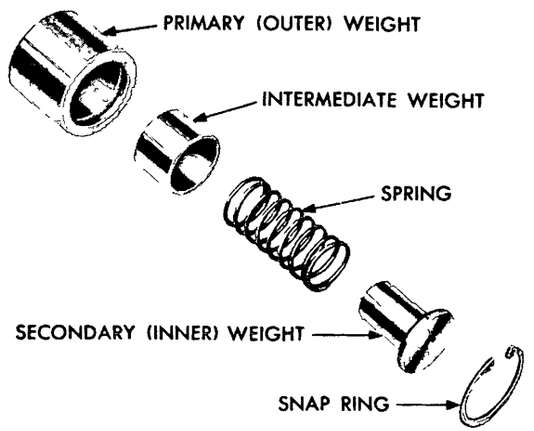
CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

TRANSMISSION OVERHAUL

DISASSEMBLY

1) Place transmission assembly in stand C-3280 and turn upside down. Remove oil pan and gasket. Loosen throttle and manual control lever locking screws and slide levers off shafts. Remove throttle valve camshaft felt retainer and felt and manual valve lever shaft seal cover. Inspect these parts for wear.
2) Remove oil strainer support screws and remove oil strainer assembly. Inspect ring seals located at both outlet sides of strainer. Remove transfer plate screws and take off valve body and transfer plate assembly. *See "Valve Body & Transfer Plate Overhaul" below.*



►***CAUTION: Mating surfaces are machined and extreme care must be used to avoid damage to these parts.***

3) Remove neutral safety switch and back-up light switch and gaskets.
4) Check transmission end clearance with a dial indicator or feeler gauge by prying direct clutch assembly toward rear and measuring the distance between direct clutch and carrier housing. Pry direct clutch forward and again measure the distance between direct clutch and carrier housing. Clearance should be .043-.069". If not within limits, record the measurement for reference at reassembly.

Hand Brake Assembly: Using tool C-3281 to hold transmission to flange, remove transmission flange nut and washers. Attach puller C-452 and remove brake drum assembly. Inspect oil sealing surfaces, and lining surfaces on drum for scoring or wear. Remove transmission brake support grease shield spring (NOTE—this spring acts as a guide for the brake shoes and retains the brake support grease shield to transmission extension housing). Place a rubber band around brake shoes to hold them in position and remove brake shoe return spring. Remove brake anchor shoe washer and brake shoe guide. Remove both brake shoe assemblies, adjusting sleeve, nut, screw and brake shoe operating lever link. Remove brake support grease shield from extension housing. *(CAUTION—If a screwdriver or sharp instrument is used to remove the shield, care must be taken not to damage neoprene sealing surface at bottom of shield).* Slide brake support assembly from rear extension housing and anchor. Inspect neoprene spacer for deterioration and note the steel sleeve used between spacer and extension housing.

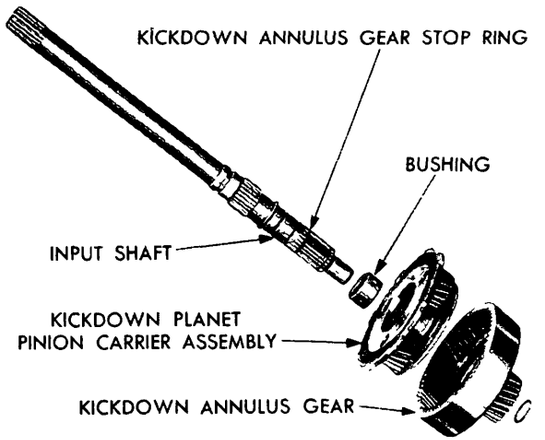
Transmission Extension: Remove speedometer drive pinion. *(CAUTION—Nylon gear can be damaged if extension housing is removed without first removing the speedometer drive pinion).* Using puller C-748, remove the output shaft rear bearing oil seal and remove any burrs from counterbore of extension housing. Remove the transmission-to-extension screws and lockwashers. Install guide studs C-3283 and attach puller C-3282. Pull extension housing from output shaft support assembly and remove extension gasket. *(CAUTION—Use care when removing extension housing to prevent damage to governor housing).* Inspect extension housing for cracks in casting and remove burrs from gasket surface. Clean output shaft rear bearing and dry with compressed air. Check bearing for rough spots but do not remove from housing unless it is found to be defective. Using a pair of long nose pliers, remove output shaft rear bearing snap ring. Using driver C-3275, drive output shaft rear bearing out rear of extension housing. Remove vent from top of extension housing and make sure it is clear of foreign matter and is open.

Governor: Using a sharp instrument, remove either of the governor valve snap rings. Remove governor valve shaft and valve from governor body. With snap ring-pliers, remove governor weight assembly snap ring (large), and remove governor weight assembly from governor body. Using C-3229 pliers, remove governor secondary weight snap ring. *(CAUTION—Keep thumb pressure against secondary weight when removing snap ring as it is spring loaded).* Remove secondary weight and spring. Inspect all parts for burrs or wear. Check secondary weight for free movement in primary weight by placing secondary weight in primary weight without spring. Primary weight should fall freely when both parts are clean and dry. Check spring for distortion. Remove governor locating screw from governor body and output shaft *(make sure that screwdriver used fits slot in screw perfectly to avoid damage to governor body).* Slide governor body and support from output shaft. Remove the two governor support piston rings and inspect closely. *(CAUTION—Governor* support has pressed in steel sleeve which routes oil through the support. Make sure these passages are open. Do not attempt to replace sleeve if damaged, replace support). Clean passages with air and inspect valve and governor body for slight scores. Remove the four governor body-to-support screws and lockwashers and separate body from support.

3-STAGE GOVERNOR ASSEMBLY

Rear Oil Pump: Remove oil pump housing-to-output shaft support screws and lockwashers and remove housing and oil pump gear. Use prussian blue to mark front side of gear in housing *(DO NOT USE A SCRIBE).* Inspect machined surfaces for nicks and burrs, oil pump gear and housing for being scored or pitted, and pump housing plug for leaks. Remove rear oil pump pinion from output shaft and mark front side with prussian blue *(CAUTION—Oil* pump pinion keyed to shaft by a small ball. Use care when removing pinion not to lose ball). Check pinion keyway and ball pocket for pitting or scoring. Using tool C-3335 and feeler gauge, check clearance between pump housing face and face of gears. Clearance limits are from .001-.003".

Center Assembly (Output Shaft Support, Planet Pinion Carriers, and Direct Clutch Assemblies): Remove output shaft support-to-transmission case screw and washer. With one hand, work output shaft up and down, and at the same time apply pressure with the other hand to the input shaft. Slide output shaft rear support assembly, planet gear housing assembly and gasket from rear of transmission case. If rear support is stuck to transmission case and cannot be removed as just described, then proceed as follows: Install one of the oil pan screws into transmission case and with the aid of a pry bar, pry against support sufficiently to separate support from case. Remove direct clutch piston retainer assembly from torque converter reaction shaft. Remove direct clutch piston retainer thrust washer from torque converter reaction shaft. This washer is a select fit and controls end clearance between direct clutch assembly and carrier housing. Inspect washer for cracks, burrs and wear.



Planet Pinion Carrier Removal from Housing Assembly: Place unit in an upright position in tool C-3285. Using a feeler gauge, check clearance between kickdown planet pinion carrier housing snap ring and kickdown planet pinion carrier assembly. This clearance should be .012-.038". If within these limits, then identify each thrust washer as it is removed. Using a screwdriver, remove transmission kickdown planet pinion carrier housing snap ring. Identify snap ring to aid in assembly (ring is not a selective fit). Proceed as follows:
1) Remove input shaft, kickdown planet pinion carrier assembly and kickdown annulus gear from carrier housing. Remove reverse planet pinion carrier thrust washer and inspect for cracks, burrs and wear. Remove kickdown annulus gear snap ring. Remove kickdown annulus gear from input shaft and inspect for worn, cracked or broken teeth.
2) Remove kickdown planet pinion carrier assembly from input shaft and carefully inspect stop ring on end of shaft which controls position of annulus gear on input shaft. Check all oil passages in both gear and shaft for obstructions. Inspect splines and bearing surfaces for burrs and wear. On early cars, inspect the three seal rings on input shaft for broken ends and make sure they are free to rotate in grooves.
3) Inspect planet pinion carrier for scores on thrust surfaces, broken and worn teeth. Using a feeler gauge, check end clearance on individual planet gears, clearance should be .006-.017". Inspect pinion shafts for tight fit in carrier and make sure pinions are free to rotate on shafts. Check oil holes in gears and shafts for obstructions. Inspect oil holes in the thrust washer of the kickdown carrier to make certain they are open *(NOTE—Do not replace planet pinion carrier assembly unless the above inspection indicates that it is necessary. This assembly is serviced only as a complete unit).*
4) Remove reverse planet pinion carrier assembly from planet pinion carrier housing. Inspect in the same manner as for planet pinion carrier (3 above). Remove output shaft and reverse annulus gear as-

CONTINUED N NEXT PA E

POWERFLITE (Cont.)

sembly from carrier housing and output shaft support. Remove reverse annulus gear snap ring and remove annulus gear from shaft. Inspect thrust surfaces, journals and inner bushings for scores. Check annulus gear for worn or broken teeth. Inspect ring grooves for burrs and ring for broken ends. Inspect splines on both shaft and gear for burrs and wear. Check speedometer pinion gear and gear output shaft, and shaft bushing for burrs, wear and scoring.

5) Remove planet pinion carrier housing thrust washer and check for cracks or wear. Remove planet pinion carrier housing from output shaft support and inspect driving lug slots inside of housing for wear. Inspect bearing and thrust surfaces for scores and burrs. Closely inspect band contacting surface for burned spots and scoring, especially if lining has worn excessively. Inspect all oil passages in output

INPUT SHAFT ASSEMBLY

shaft and support for obstructions. Check rear oil pump mating surface for burrs and scores, and check for stripped threads in support.

Direct Clutch Piston Retainer: 1) Using a screwdriver remove kickdown sun gear snap ring. Identify this ring so it can be returned to the same position (selective fit). Lift out sun gear assembly. Check for clutch material obstructing oil passages and slinger and remove any metal pickup which might have accumulated on front side. Inspect for cracked or broken teeth.

2) Lift out direct clutch hub from center of direct clutch piston retainer. Inspect driving lugs for wear and remove any metal pickup accumulated on either side of hub. Invert the direct clutch piston retainer and remove clutch plates (steel) and driving disc assemblies (five or six of each used, depending on car model), noting position in which these parts were assembled. *(CAUTION*—If assembly was started with cork portion on outer top, the same sequence will follow all through the assembly and when unit is reassembled the same sequence should be followed to assure smooth operation). Inspect driving discs for evidence of wear, burning, glazing, and flaking off of facing material. Check discs by scratching with finger nail and if material collects under nail, replace discs. Inspect splines in discs, replacing any that are damaged. Inspect steel plates for burning, scoring, or damaged splines.

3) Using tool C-3302, compress direct clutch spring sufficiently to unseat clutch spring retainer snap ring. Release tool C-3302, and remove direct clutch spring retainer snap ring, spring retainer and spring from direct clutch piston retainer. Using a twisting motion remove direct clutch piston assembly from clutch retainer. Air pressure may be used to blow piston out if it is tight.

4) Inspect ball check in clutch retainer housing to make sure it is free. The bearing used in direct clutch piston retainer is a steel back bronze type and is **not replaceable.** If torque converter reaction shaft seal rings have worn or grooved the bearing so that bronze is no longer visible at that point replace the direct clutch piston retainer. Inspect band contacting surfaces for deep scores and burns, especially if band lining is worn to point where steel band has been contacting direct clutch piston retainer. ***(CAUTION—Do not turn clutch piston retainer in lathe to remove score marks).*** Inspect steel clutch plate contacting surfaces for deep scores, replace as needed. Make sure clutch driving lugs will slide freely into retainer. Inspect inside bore for score marks, and if light, remove with crocus cloth, if heavy, replace piston.

5) With tool C-3286, unlock direct clutch piston retainer seal ring and remove from retainer. Inspect for wear and broken ends. Remove direct clutch piston seal ring (neoprene) from piston. Inspect for deterioration and hardness.

Reverse & Kickdown Band Assemblies: Mark reverse band for installation purposes, then compress ends of band sufficiently to remove reverse band strut. Unhook reverse band assembly from link assembly and remove by rotating band ends through rear opening in transmission case. Repeat with kickdown band, noting that strut is grooved to act as a guide to strut pin on band end. Remove from case in same manner as for reverse band. Inspect linings for wear and bonding to metal band. If lining is worn to point where grooves are no longer visible, replace band. ***(CAUTION—Do not attempt to reline bands.)*** Check bands for distortion and cracked ends.

Reverse & Kickdown Band Lever Assemblies: ***(CAUTION—Inspect these link assemblies and levers for cracks or wear, making sure they have side clearance and are free to turn on shafts. Do not remove these assemblies unless inspection reveals that it is necessary).*** If necessary to remove, proceed as follows: Insert finger in back of reverse band and link assembly lever shaft, and holding the reverse band lever and link assembly with the other hand, push shaft out rear opening in transmission case. Remove kickdown band lever shaft plug in front of transmission case and remove kickdown band lever in same manner as for reverse band, except that shaft is removed from front of transmission case.

Front Oil Pump: 1) Remove transmission regulator valve spring retainer, spring, gasket and valve. Remove torque converter control valve spring retainer, spring, gasket and valve.

2) Remove front oil pump-to-transmission case screws and washers (discard aluminum or copper sealing washers, new ones must be used at reassembly). Remove housing by tapping gently with a fibre hammer (if front pump housing has two threaded holes, attach puller C-3287 and guide studs C-3288 and pull housing and gears from transmission case). Use prussian blue to mark front side of gears ***(CAUTION—Do not scribe gears for identification).***

3) Remove front oil pump housing seal (large neoprene) from housing, and inspect for deterioration and hardness. Using a brass drift, drive housing dust seal out front of housing. Inspect housing bushing for scores. Remove light scores with crocus cloth and if bushing scored heavily, replace housing (bushing is not replaceable). Check housing and gears for scores.

4) Using tool C-3335 and feeler gauge, check clearance between pump housing face and face of gears. Clearance limits are from .001" to .003". Make sure all oil passages are clear by blowing out with compressed air.

Regulator Valve Body: Using the two holes provided in regulator valve body, attach puller C-3287, and install guide pins C-3288. Pull regulator body off torque converter reaction shaft. Place body and both valves in pan containing clean solvent, wash thoroughly and dry with compressed air. Check valves for free movement in body, these valves should fall in and out of bores when both valves and body are dry. *(CAUTION*—If crocus cloth is used to polish valves, care must be taken not to round off the sharp edges of valve.) Check for all passages for obstructions and all mating surfaces for burrs or distortion. If body has a slight nick or raised portion on a mating surface, it can be removed with a surface plate and crocus cloth. Check regulator valve spring seat (snap ring) for proper seating. Wrap valves and body in separate cloths until ready for installation.

Reverse Servo Piston: Lift out reverse servo piston sleeve. Inspect inside bore, lever, and contacting surface on piston sleeve for scores and wear. Make sure the two bleeder holes are open. Install tool C-3289 on transmission case and compress reverse piston spring retainer. Using a screwdriver, remove the reverse servo piston and valve assembly spring retainer snap ring, and loosen compressing portion of tool. Remove spring retainer, spring, servo piston and valve assembly. Remove servo piston ring (lip type neoprene) from piston and inspect for distortion and hardness. Remove reverse servo piston valve snap ring. Remove spring and valve from piston. Inspect servo bore for scores and remove light scores with crocus cloth.

Kickdown Piston: Using tool C-3289, apply sufficient pressure on kickdown piston rod guide and remove the snap ring. Loosen compressing portion of tool and remove tool from transmission case. Remove piston rod guide, piston spring, kickdown piston rod assembly, and kickdown piston cushion spring. Inspect riveting of kickdown piston rod to kickdown piston spring retainer. Remove seal ring from guide and inspect for light scores and wear on piston rod and guide. Using C-484 pliers, remove kickdown from transmission case. Remove the three snap rings (two locking and one open type) from kickdown piston. Inspect rings for scores or broken ends, and piston for wear.

CONTINUED ON NEXT PAGE

POWERFLITE (C nt.)

Torque Converter Reaction Shaft: *(CAUTION—Inspect shaft seal rings (interlocking type) for broken ends and make sure they are free to rotate in grooves. Inspect inside of shaft for burrs, and splines for burrs and wear. Check thrust surfaces for wear and slight scores. Do not remove reaction shaft from case unless inspection reveals that it is necessary).* If shaft must be removed, proceed as follows: Remove shaft seal (neoprene). Using a suitable brass drift, remove shaft dowel pin from shaft flange and transmission case. Remove transmission case-to-reaction shaft screws and using tool C-3297, press shaft out of transmission case. Remove the two shaft seals (interlocking).

Manual Control Valve Lever Shaft Oil Seal: Drive seal out of case with a suitable drift.

Kickdown Band Adjusting Screw: Loosen locking nut and remove kickdown band adjusting screw and locknut. *CAUTION—When locknut is loosened, the adjusting screw must be finger free. If not, inspect screw and nut for pulled threads or foreign material on threads. Freeness of this screw is very important to adjustment.*

Transmission Case Inspection: Inspect case for cracks, sand holes and stripped threads. Check for burrs on mating surfaces. Blow compressed air through all passages to make sure they are open. Check oil hole plugs for tightness.

REASSEMBLY

Kickdown Band Adjusting Screw: Install adjusting screw in transmission case until there is approximately 1" of screw left outside case. Do not lock screw into position at this time.

Manual Control Valve Lever: Using tool C-3277, start seal squarely and tighten until seal is flush with case.

Torque Converter Reaction Shaft: *(NOTE—Reaction shaft should only be removed if inspection indicates that it is faulty).* Heat front face of transmission case to 170-190°, using sun lamps for the purpose.

1) Coat the two shaft interlocking seal rings with Lubriplate and install on shaft and lock in place. Make sure the rings are free to rotate in lands. Coat the portion of shaft that presses into case with Lubriplate and position shaft into front of transmission so holes in shaft line up with screw holes in case.

2) Place a 5/16" (.308-.311" outside diameter in unthreaded section), 2¼" long bolt through dowel guide pin holes in case and reaction shaft to act as guide, install nut. Using tool C-3297 press shaft into place. Do not remove 5/16" bolt at this time. Start the three transmission case-to-reaction shaft screws and washers and tighten slightly, but do not torque.

3) Remove 5/16" bolt from dowel hole and install the reaction shaft dowel from inside case. Torque the case-to-reaction shaft screws to 10-15 ft. lbs. Coat neoprene reaction shaft seal and install on shaft.

Kickdown Piston: 1) Coat the three kickdown piston rings (two locking and one open type) with Lubriplate and install on piston. Lock into position and make sure they are free to rotate in lands. Place kickdown piston assembly into transmission case, compress bottom ring with a brass rod (flatten end), and push piston into place.

►*CAUTION: After bottom ring has entered, piston will seem to hang at two different locations while being pushed into case. This is due to rings entering cylinder. If any of the rings should be broken when piston assembly is being installed, transmission will not operate properly.*

2) Place cushion spring in piston and install tool C3289 on transmission case. Place piston rod assembly in piston and slide piston spring over piston rod assembly. Coat piston rod guide seal ring with Lubriplate and install on rod guide. Make sure ring rotates in groove.

3) Place piston rod guide assembly on piston rod assembly and using extreme care, compress the kickdown piston spring to the point where piston guide seal ring slightly binds on case. Using a piece of brass rod (flattened on end), work seal into position, gradually compressing spring until seal ring enters case and snap ring can be installed. Install snap ring, making sure it is properly seated.

Reverse Servo Piston: 1) Place reverse servo piston valve and spring in reverse servo piston, with shaft protruding through hole in bottom of piston. Using pliers C-3229, install reverse servo piston valve spring snap ring and make sure it is seated.

2) Coat servo piston ring with Lubriplate and install on piston. Insert piston and valve assembly into transmission case in a cocked position, then by rotating piston, the piston ring will enter case without damage.

3) Place servo piston spring over piston and position spring retainer over spring. Compress spring with tool C-3289 sufficiently to install snap ring, making sure it is seated. Inspect interior of servo sleeve for burrs, then place sleeve over piston, making sure sleeve slides freely on piston by working it up and down. Remove installing tool from transmission.

Regulator Valve Body: 1) Inspect regulator valve body and valves to make sure that no damage has occurred since disassembly and blow out passages with air.

2) Coat reaction shaft seal (neoprene) with Lubriplate if not already done, and place regulator valve and torque converter control valve in regulator valve body. Install guide studs C-3288 in front transmission case.

3) Place regulator valve body assembly, with oil passages to rear, over reaction shaft and onto guide studs *(CAUTION—When reaction shaft seal enters regulator body use care to prevent shaft screws damaging passages on regulator body)*, seat firmly to front of transmission case.

Front Oil Pump: 1) Position front oil pump housing dust seal in oil pump housing with metal portion of seal down. Using driver C-3278, bottom seal in housing. Coat housing seal (large neoprene seal) with Lubriplate and install on housing.

2) Place front oil pump gear and pinion (driving lugs on pinion facing up, and prussian blue marks made at time of disassembly toward front) in pump housing. *(CAUTION—Oil pump pinion must be installed correctly or damage will result when installed in transmission.)* Lubricate pump gears with transmission fluid.

3) Place pump housing assembly over reaction shaft and slide into position over guide studs until pump housing seal is flush with transmission case. Using new aluminum or copper washers on screws, start five of the screws and draw housing down evenly until it is seated into transmission case. Remove guide studs and install two remaining screws and washers. Torque all screws to 12-17 ft. lbs. *NOTE—After all screws have been installed and torqued, engage driving lugs of oil pump pinion to determine if pinion turns freely. Use the oil pump drive sleeve for this check. If not free, remove pump and check for foreign matter between gears and housing.*

4) Using a new gasket, install torque converter control valve spring and retainer. Torque to 35-40 ft. lbs. Install regulator valve spring and retainer, using a new gasket, and torque to 45-50 ft. lbs.

Reverse Band, Kickdown Band & Lever Assemblies: *NOTE—If lever assemblies were not removed, omit the operations covering their installation.*

1) Place kickdown band lever assembly in transmission case and slide band lever shaft into position from front of case, making sure it operates freely. Install band lever shaft plug and torque to 30-35 ft. lbs. Place kickdown band assembly into transmission case by rotating ends of band through opening in case. Fit proper end of band over adjusting screw and compress band sufficently to install band strut between other band end and band lever. *CAUTION—Make sure band strut slot engages with kickdown band strut pin in band end.*

2) Place reverse band lever assembly in reverse band link assembly and position into transmission case, aligning holes in lever and link assemblies to holes in transmission case. Slide band lever shaft into position from rear of transmission case. Shaft is held in position by rear output shaft support.

3) *(NOTE—If new reverse band is to be installed, back adjusting screw out until approximately 1" of screw is above lever on locknut side.)* Place reverse band assembly into transmission case by rotating ends of band through rear opening in case. Hook correct end of band (previously identified when band removed) in link assembly. Compress band sufficiently to install band strut in slots of reverse band and band lever assembly.

►*DIRECT CLUTCH RETAINER & KICKDOWN BAND ASSEMBLY SERVICE REPLACEMENT NOTE:* A new Kickdown Band Assembly, Part No. 1854128, and a new cast iron Direct Clutch Retainer are used in production beginning with 1959 models. The later type Kickdown Band Assembly MUST be used with the cast iron Direct Clutch Retainer and may be used with the earlier type steel retainer. Both parts are interchangeable with previous models as a complete unit.

Direct Clutch Piston Retainer: 1) Coat direct clutch seal ring with Lubriplate and install on piston, with lip of ring facing away from the flange. Coat clutch piston retainer seal ring with Lubriplate and install on retainer hub. Using tool C-3286, lock seal into position and make sure it is free to rotate in lands. Place piston assembly in clutch retainer, and with a twisting motion, seat piston in bottom of retainer, being careful not to damage lip of seal.

2) Seat clutch spring into piston retainer and position spring retainer and snap ring on spring. Using tool C-3302, compress clutch spring sufficiently to seat the snap ring. *NOTE*—Piston spring retainer may require guiding past the snap ring grooves. Make sure snap ring properly seated.

3) Place clutch hub in center of clutch piston re-

C NTINUED N NEXT PAGE

POWERFLITE (C nt.)

tainer Lubricate all clutch plates and driving discs with automatic transmission fluid and assemble by placing one of the clutch plates in clutch piston retainer, followed by a driving disc. ***(NOTE—Install discs in the same manner they were removed. If first driving disc was installed with cork portion on outer top, then the remaining discs must be installed in the same manner, or vice versa. Repeat this procedure until all six discs and plates have been installed.)***

4) Place kickdown sun gear assembly in direct clutch piston retainer and install snap ring (this ring is a selective fit and must be checked as follows) Using a feeler gauge, check clearance under kickdown sun gear snap ring Clearance limits should be as close to zero as possible Rings are furnished in three sizes for selective fitting Part No 1327729 (.059-.061"), No 1327730 (.062-.064"), No 1327731 (.065-.067").

Planet Pinion Carriers: 1) Place output shaft support in tool C-3285 with bearing surface up Lubricate bearing surface of planet pinion housing and place bearing surface of housing over output shaft support bearing surface Place reverse annulus gear on output shaft and install snap ring (Output shaft may be placed in vise, providing vise is clean and equipped with brass jaws) ***(CAUTION—Reverse annulus gear must be tight fit on shaft. End clearance is controlled by various snap rings which are furnished in the following three thicknesses: Part No. 1329608 (.078-.080"), No. 1329609 (.082-.084"), No. 1329610 (.086-.088"). Make sure that snap ring is properly seated.)***

2) Coat output shaft seal ring with Lubriplate and install on shaft Lock into position and make sure ring rotates freely in groove Coat planet pinion carrier housing thrust washer with Lubriplate, slide over output shaft and into position in reverse annular gear Place output shaft and reverse annulus gear in position in carrier housing and through output shaft support, being careful not to damage shaft seal ring as it enters shaft support ***Check to see that planet pinion carrier thrust washer seats properly between annular gear and carrier housing.***

3) Lubricate thrust surfaces and gear teeth of reverse planet pinion gear and carrier assembly, and place carrier assembly in reverse annulus gear ***(CAUTION—Make sure driving lugs on carrier assembly properly engage slots in planet pinion housing.)***

4) On early cars, coat input shaft seal rings with Lubriplate and lock into position, making sure rings rotate freely in lands (Later cars have a large bearing area (bushing) on shaft replacing the three seal rings. ***See "Input Shaft Production Change" above for installation of later type shaft in early cars). (CAUTION—Inspect stop ring for proper position in input shaft groove).*** Lubricate thrust surfaces and gear

GEAR TRAIN (PLANET PINION CARRIER)

teeth on kickdown planet pinion gear and carrier assembly. Slide assembly with collector ring up, carefully down on rear end of input shaft and over stop ring. Lubricate teeth and thrust surfaces and install kickdown annular gear onto input shaft, down to stop ring. Install kickdown annulus gear snap ring and make sure it is seated (Input shaft can be installed in vise providing it is clean and equipped with brass jaws).

5) Engage teeth of kickdown planet pinion gears with teeth on kickdown annulus gear Slide pinion gear and carrier assembly into position in kickdown annulus gear Coat reverse planet pinion carrier thrust washer with Lubriplate and install on kickdown annulus

6) Place kickdown planet pinion carrier assembly, annulus gear and input shaft into position in planet carrier housing Make sure planet pinion carrier thrust washer remains on annulus, and driving lugs on carrier assembly properly engage slots in planet pinion housing Install planet pinion housing snap ring (not selective fit), making sure it is positioned and seated properly Lubricate gears and splines

7) Using a feeler gauge, check clearance between kickdown planet pinion carrier housing snap ring and the kickdown planet pinion carrier assembly Limits are .012-.038" If not within these limits disassemble and recheck reverse planet pinion carrier and planet pinion carrier housing thrust washers

Center Assembly (Output Shaft Support, Planet Pinion Carriers, and Direct Clutch Assemblies): 1) Coat kickdown planet pinion thrust washer with Lubriplate, place over kickdown sun gear and on to thrust surface of direct clutch piston retainer assembly Place direct clutch piston retainer assembly over input shaft, engaging sun gear with kickdown planet pinion gears and engaging splines of input shaft with direct clutch hub Make sure kickdown planet pinion carrier thrust washer remains in position

►***DIRECT CLUTCH PISTON RETAINER THRUST WASHER (CAUTION:*** This thrust washer controls transmission endplay clearance and is a selective fit After transmission is reassembled, except for hand brake assembly, the endplay clearance must be checked and corrections made in the washer thickness as necessary. ***See "Checking Transmission Endplay" below***

2) Coat direct clutch piston retainer thrust washer with Lubriplate and install on torque converter reaction shaft inside transmission case Use care when sliding washer over rings to prevent damage

3) Install guide studs C-3283 in rear of transmission case, position new output shaft support gasket over guide studs and on to case Place tool C-3306 over splines on front of input shaft

4) Insert input shaft, with direct clutch assembly, planet pinion carrier housing, output shaft support and output shaft attached, through rear of transmission case and through transmission reaction shaft Then guide assembly through bands and over guide studs into position in transmission case Remove tool C-3306 from front of input shaft

►***CAUTION: Do not force assembly into case. Avoid damage to seal rings on torque converter reaction shaft.***

5) Install one output shaft support-to-transmission case screw and lockwasher finger tight

Rear Oil Pump: 1) Coat oil pump pinion ball with Lubriplate and insert in ball pocket in output shaft Lubriplate oil pump drive pinion, place over shaft and slide into position, aligning keyway in pinion with ball in shaft ***Make sure pinion is installed with side marked with prussian blue at disassembly, is toward front.***

2) Slide pump housing assembly over output shaft and into position against output shaft support Install five rear oil pump housing-to-output shaft support screws and lockwashers ***(CAUTION—There are two extra holes in housing which are used for vents. Make sure screws are not installed in these holes. Check each screw hole before installing screws).*** Draw screws down evenly and tighten to 15-20 ft lbs. torque. When screws have been properly tightened, check output shaft for free rotation of pump gears. If not free, disassemble pump to determine cause.

Governor: 1) Coat the two governor support piston rings with Lubriplate and install on governor support Stagger rings and make sure they are free. Position governor body on support, install the four screws and lockwashers ***but do not tighten at this point.***

2) Slide governor support and body assembly over output shaft and into position in rear pump housing, compressing governor support piston rings with fingers as support enters oil pump housing.

3) Align locating hole in output shaft to locating screw hole in governor body and install governor locating screw, tighten to 3½-4 ft. lbs. torque. ***NOTE—Holes can be easily aligned by turning output shaft and holding governor body. Make sure screw driver attachment fits the screw slot when tightening locating screw.***

4) Tighten the four governor body screws to 5-10 ft. lbs torque.

5) Dry governor parts with compressed air but do not lubricate when assembling. Place governor weight spring over secondary weight and position both in primary weight, making sure springs seat properly. Guide secondary weight, and compress governor weight spring sufficiently to install snap ring. Make sure ring is properly seated. Place governor weight assembly, with secondary weight snap ring up, into governor body and install snap ring, making sure it is seated.

6) Slide governor valve, with small end up, over governor valve shaft. Slide governor shaft into governor body through output shaft and governor weight assembly, at same time positioning valve into body. Install governor shaft snap ring and make sure it is securely locked to shaft. Check operation of governor weight assembly and valve by turning output shaft. Both should fall freely in body.

Transmission Extension: ***NOTE—If output shaft rear bearing was not removed, omit operation covering its installation.***

1) Using driver C-3204, install output shaft rear bearing in extension housing. Make sure it is properly seated then lubricate with automatic transmission fluid. Install output shaft bearing snap ring, bevel side up, making sure it is properly seated.

2) Replace extension breather and tighten to 10-12 ft. lbs. torque. Install new transmission extension gasket over guide studs and into position against output shaft support. ***Do not use sealing material on***

C NTINUED N NEXT PAGE

Form 53 A

POWERFLITE (C nt.)

gasket. Using care not to damage governor housing, place extension housing over output shaft and onto guide studs. Using tool C-496 with adapter C3284, press extension housing into position against output shaft support.

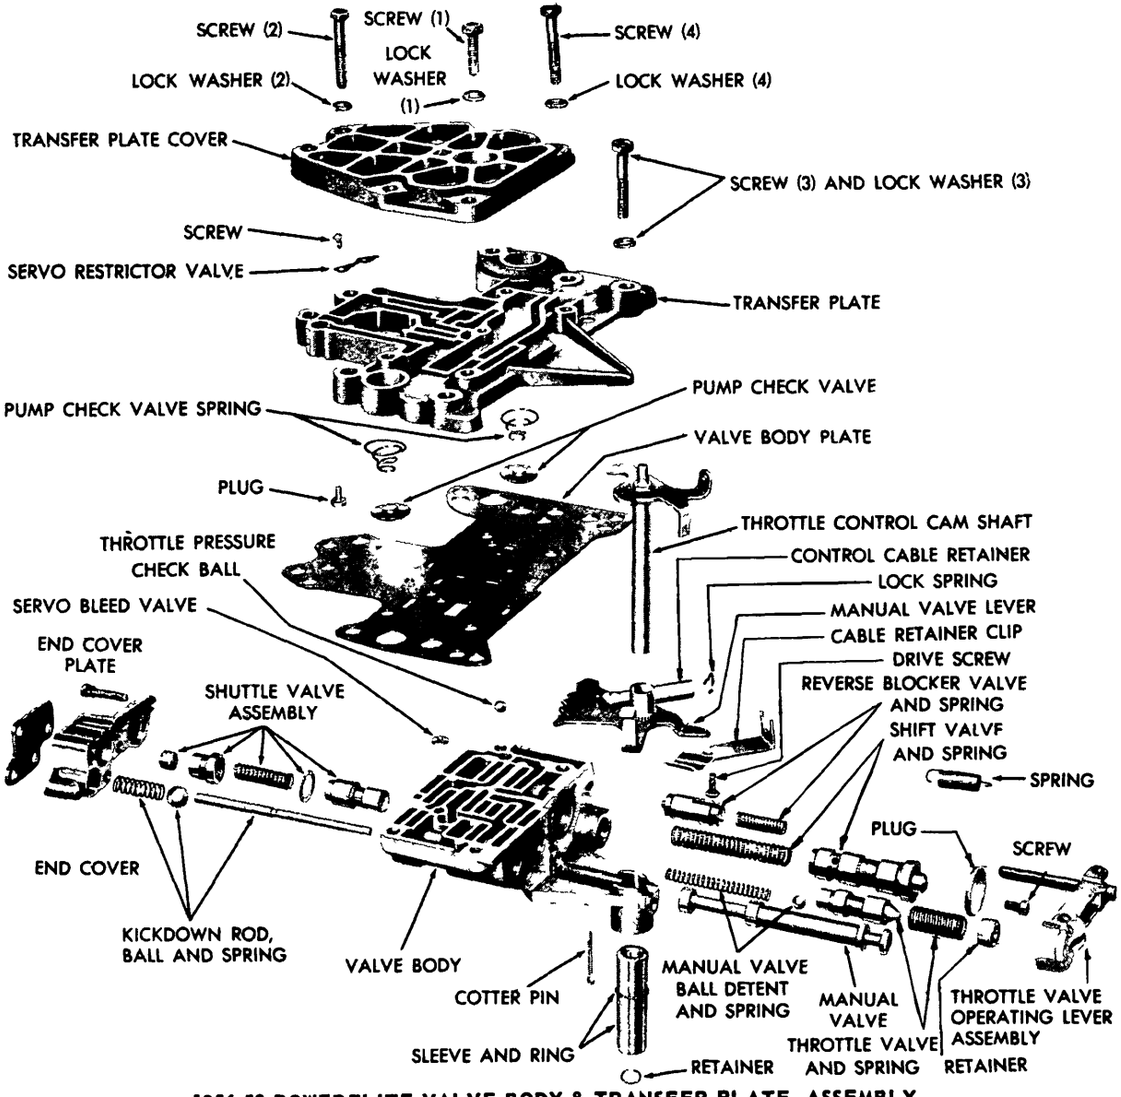
3) Start the seven transmission extension-to-case screws and lockwashers, then draw down evenly and tighten to 25-30 ft. lbs. torque. Tighten output shaft support-to-case screw to 25-30 ft. lbs. torque. ***Check to see that output shaft turns freely.***

4) Coat nylon gear and threads on speedometer drive pinion with Lubriplate and install in extension. Tighten to 40-45 ft. lbs. torque.

Checking Transmission Endplay: Using dial indicator C-430 or feeler gauge, measure the distance between direct clutch assembly and carrier housing when clutch is in **rearward** position. Using a screwdriver inserted between the direct clutch assembly and carrier housing, carefully pry direct clutch **forward.** Remove screwdriver and measure again. The difference in measurements is the end clearance and must be .043-.069". If it does not fall within these limits, proceed as follows:

1) Remove the seven screws and lockwashers from transmission extension and install guide studs C-3283. Then remove the one output shaft support-to-case screw and washer, and remove extension housing, output shaft, support, and planet pinion carrier housing assembly as a unit.

2) Slide direct clutch piston retainer from torque converter reaction shaft and remove direct clutch piston thrust washer. Using a micrometer, measure thickness of the washer and then select a washer to give correct clearance. These washers are available in the following five thicknesses: Part No. 1406442 (.125-.130"), No. 1406443 (.135-.140"), No. 1406444 (.145-.150"), No. 1406445 (.155-.160"), No. 1406446 .164-.170").



3) To install, reverse removal procedure. Using driver C-3205, install output shaft rear bearing oil seal.

Hand Brake Assembly: 1) With brake support spacer in position on back of brake support and spacer sleeve in center of support, slide brake assembly over rear extension housing and anchor pin. Make sure spacer sleeve remains in center of support. Install brake support grease shield on extension housing. ***NOTE—Indent in shield for correct positioning on extension housing. Shield must be located on housing far enough to permit installation of spring later.***

2) Place both anchor brake washers on brake shoe anchor and install locking washer. Place both shoe assemblies with adjusting sleeve nut and screw into position on anchor. Make sure brake shoes are between the anchor washers. Use a rubber band around shoes to help hold them in position.

3) Install operating link (marked for correct installation), and brake shoe support grease shield spring (with opening in spring toward adjusting sleeve). Make sure spring is properly seated in groove. Slide brake shoe return spring behind grease shield spring and hook into position in holes in brake shoes.

4) Make sure adjustment is loose enough and install brake drum assembly. If necessary, use tool C-496 to press brake drum on output shaft. Install transmission flange washer, shakeproof washer and nut, and tighten to 140-160 ft. lbs. torque.

1956-58 POWERFLITE VALVE BODY & TRANSFER PLATE ASSEMBLY

Kickdown Band Adjustment: Turn transmission on side and using tool C-3291, loosen locknut and tighten kickdown adjusting band adjusting screw to 60-72 inch lbs. torque. With the counter on C-3291, **back adjusting screw out 3 turns,** then holding adjusting screw stationary with short handle, tighten locknut securely. ***Use extreme care to assure correct adjustment.***

Reverse Band Adjustment: Remove reverse band adjusting screw locknut and tighten adjusting screw to 20-25 inch lbs. torque, then back out adjusting screw 10 turns. Holding adjusting screw in this position, replace adjusting screw locknut and tighten to 30-35 ft. lbs.

Valve Body & Transfer Plate: 1) Install neutral safety switch, back-up light switch and gasket, and tighten to 15-20 ft. lbs. torque. Clean mating surfaces and check for burrs on transmission case and valve body. Place valve body and transfer plate into position on transmission case and install five transfer plate screws and lock washers ***(Install the two 1⅝" long screws through transfer plate cover on valve body),*** tighten to 12-17 ft. lbs. torque. Make certain the two oil strainer tube seals are in position on oil strainer, and place oil strainer in position on valve body. Install oil strainer support screws and lock washers

C NTINUED N NEXT PA E

POWERFLITE (C nt.)

and tighten to 12-17 ft. lbs.

2) Place manual valve lever shaft seal cover over manual shaft and install manual control lever with arm side of lever against cover, on manual valve shaft. Tighten locking screw. Place throttle valve camshaft felt and retainer over throttle valve shaft. Install lever assembly on throttle camshaft, and tighten locking screw. Check operation of controls by shifting manual control into the four operating positions.

3) Check throttle cam position in throttle operating lever assembly and throttle camshaft assembly for kickdown operation. Visually check manual lever contact on neutral safety and back-up light switches.

4) Install oil pan, using a new gasket, and tighten attaching screws to 12-17 ft. lbs., drawing screws down evenly. Tighten drain plug to 20-25 ft. lbs. torque.

VALVE BODY OVERHAUL

C ntr l Valv Ass mbly: A reverse blocker valve has been added to the control valve assembly. Remove the reverse blocker valve by removing the cotter pin and spring, then rotate valve out of its bore. Donot remove push button unit control adapter, lock spring, or cable adapter clip unless inspection indicates that it is necessary. See "Control Valve" illustration for removal and installation of valve components.

Valve Body & Transfer Plate Disassembly: Place valve body and transfer plate assembly in holding fixture C-3294. DO NOT USE VISE TO HOLD TRANSFER PLATE ON VALVE BODY.

1) Remove two of the long transfer plate cover screws and lock washers and install guide studs C-3295. Keeping finger tight pressure against transfer plate, remove the three remaining transfer plate cover screws, (two long & one short), and remove transfer plate cover. Using care not to lose the servo restrictor valve operating plug from transfer plate, remove transfer plate from valve body plate. *NOTE—Rear pump check valve has metering hole in it. Note position of this valve in relation to the front pump check valve (without metering hole).*

2) Remove valve body plate from valve body, noting position of throttle pressure check valve ball, and servo bleed valve (servo bleed valve may stick to valve body plate). Remove these parts and place in clean container. Remove throttle valve cam spring from cam and operating lever. Compressing the throttle valve operating lever assembly against throttle valve spring, slide throttle valve cam assembly from manual lever assembly *(CAUTION—Remove any burrs from throttle valve camshaft and manual valve lever shaft before sliding them from valve body).*

3) Swing throttle valve operating lever out of way and remove throttle valve spring and retainer from throttle valve. Remove throttle valve from valve body core. Check distance from valve body to end of throttle valve operating lever adjusting screw. This distance should be 1 11/16". Using tool C-3279, remove throttle valve adjusting screw, lock nut and throttle valve operating assembly. *NOTE—It is not necessary to remove throttle valve operating assembly unless parts are to be replaced.*

4) Remove the four (three long and one short) valve body end cover plat screws and lock washers and remove valve body end cover plate. Remove valve body and cover screw, keeping pressure against cover to avoid losing the three springs behind it. Carefully remove valve body cover so as not to lose any of the springs or kickdown valve ball. Remove shuttle valve plug *(CAUTION—This plug has an adjustment, but do not disturb this setting as it is adjusted during manufacture).* Remove kickdown valve ball from body. Remove shuttle valve by using shuttle valve spring (shuttle valve stop ring will come out with valve).

5) Remove direct clutch shift valve spring from valve body. Mark the direct clutch shift valve plug with prussian blue (in order to reinstall with right side out), then loosen plug screws sufficiently to allow removal of plug by pushing on open end of shift valve with finger. Remove shift valve, and remove valve body from tool C-3294. Place valve body on clean paper. Remove kickdown rod from cover end of valve body.

►*MANUAL VALVE AND LEVER ASSEMBLY NOTE—It is not necessary to remove this assembly unless damaged parts are to be replaced. If assembly must be removed, proceed as follows:*

6) Place manual control valve lever on lever assembly and turn it counter-clockwise until manual control valve is in low range position (last detent). Using a screwdriver, compress detent plunger and spring and continue to turn manual valve lever assembly until manual valve becomes disengaged from manual valve lever assembly. Remove manual valve from valve body bore. Remove manual control lever and slide manual lever assembly from valve body. Remove manual valve lever detent plunger and spring from valve body.

Valve Body & Transfer Plate Inspection: Wash all parts in clean solvent and dry with compressed air. Check all passages for obstructions and check for porous coating. Inspect all mating surfaces for burrs and scratches. Light scratches and burrs can be removed with crocus cloth. With a light, check bores in valve body for pits and scores. Check springs for distortion and collapse. Check mating surfaces on a surface plate for distortion. Check all moving parts for free operation, and valves for freeness in body bores. Inspect servo restrictor valve in transfer plate to make sure it is seating properly. If valve is defective, carefully remove drive screw. Install new valve and new drive screw, making sure drive screw is tight, and being very careful not to distort transfer plate when installing drive screw. Check all points in valve for wear and replace defective parts.

Valve Body & Transfer Plate Reassembly: *CAUTION—When assembling valve body and transfer plate assemblies, handle parts carefully to avoid damage, such as nicks, etc., to mating surfaces. Use a twisting motion when placing valves in their respective bores.*

1) Place manual valve lever detent plunger spring and plunger into place in valve body. Slide manual valve lever assembly into valve body. Using a twisting motion place manual valve into valve body sufficiently to engage manual valve with manual valve lever pin. Then using valve lever assembly, turn slowly in clockwise direction and at the same time using a twisting motion, guide manual valve into valve body to low range position. Make sure detent plunger is seated.

2) Place kickdown rod (small end toward end cover) into valve body, making sure it is properly seated. Place valve body in tool C-3294 and install direct clutch shift valve. Place direct clutch shift valve into position (same as when removed, and with marks made at disassembly in correct position) in valve body. Draw the two screws down evenly and torque to 24-30 inch lbs. Install direct clutch shift valve spring in valve.

3) Install shuttle valve in valve body. Coat stop ring lightly with Lubriplate and place into recess in valve body. Place shuttle valve spring in valve. Place kickdown valve ball into valve body.

4) Place valve body end cover plate on end cover. Install one short screw and lock washer. Tighten securely. Place shuttle valve plug into position in end cover, and install kickdown valve spring. Install valve body end cover onto valve body. *CAUTION—Make sure direct clutch shift valve, shuttle valve and kickdown valve spring are in correct position and properly seated when cover is being installed.* Install valve body end cover screw and lock washer, but do not tighten.

5) Install the three (long) valve body end cover plate screws and lock washers. Draw down evenly and tighten to 24-30 inch lbs. Tighten valve body end cover screw and the remaining end cover plate screw to 24-30 inch lbs.

6) Using tool C-3279, install throttle valve adjusting screw, locknut and throttle valve lever assembly. Adjust to where there is approximately 1 11/16" distance between valve body and end of throttle valve operating adjusting screw. Install throttle valve (point outward) in valve body. Place throttle valve spring and retainer over throttle valves. Swing throttle valve operating lever over spring and retainer. Compressing the throttle valve lever assembly against throttle valve spring, slide throttle valve cam assembly into manual lever assembly, indexing cam portion on throttle valve in slot of operating lever. Install throttle valve cam spring to cam and operating lever.

7) Install servo bleed valve and throttle pressure check valve ball into position in valve body and install guide studs. Position transfer plate cover on transfer plate and install the center screw (short) and lock washer finger tight. Install the servo restrictor valve operating plug (long end first) into transfer plate.

8) Make sure pump check valves and springs are properly positioned in transfer plate. The pump check valve with the metering hole should be toward the rear of transmission. Place valve body plate flush into position on transfer plate by compressing pump check valve springs. *CAUTION—Be sure pump check valves enter transfer plate, otherwise valve body plate will be damaged when assembly is later drawn down onto valve body.*

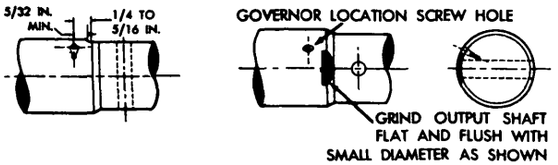
9) Keep sufficient pressure on transfer plate and valve body to hold them together. Place over guide studs and into position on valve body, and install two of the transfer plate cover screws and lockwashers (one on each side) finger tight. Recheck to see that pump check valves remained in position in valve body plate. Remove guide studs and install two remaining transfer plate cover screws and lock washers. Draw transfer plate down evenly and torque all five screws to 45-50 inch lbs. torque. *CAUTION—Avoid over tightening as this will cause valve body to warp which will result in sticky valves. Check operation of pump check valves to make sure they can be unseated by pressing down on them.*

TORQUEFLITE

Chrysler Imp rial (1956)
Chrysler & Imp rial (1957-60)
DeSoto (1957-60)
Dodge (1957-60)
Plymouth (1957-60)

►CHANGES, CAUTIONS, CORRECTIONS

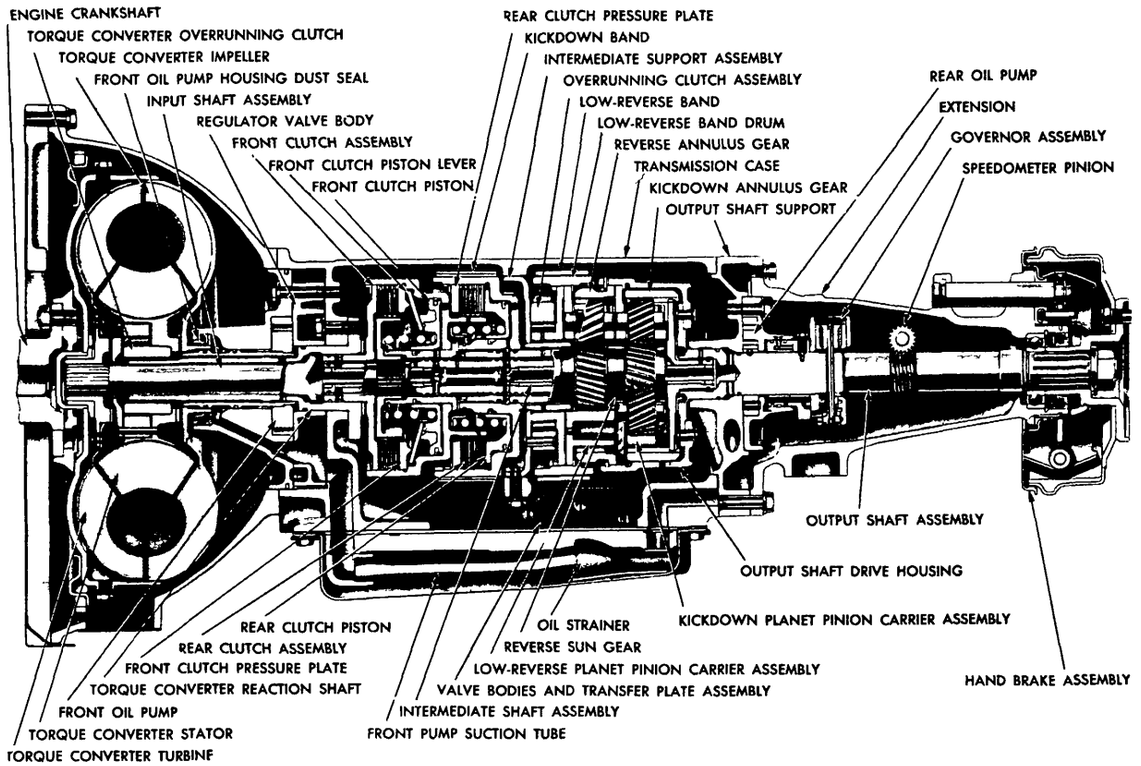
►*STARTING ENGINE BY PUSHING CAR: (Towing car to start is not recommended because of sudden surge of power when engine starts).* Turn ignition switch on, then push the "1" (Low) button in and depress accelerator pedal slightly. After car attains a speed of 15 MPH, the transmission will start engine.



►*TOWING TORQUE-FLITE CARS: Following procedure is recommended:*

Transmission Operating Properly—Car may be towed safely in "N" (Neutral) position at moderate speeds. For long distance towing (over 100 miles), the propeller shaft should be disconnected.

Transmission Inoperative—Tow car with rear end raised or remove the propeller shaft.



►*1957 TORQUEFLITE REVERSE SERVO PISTON "COCKING" CORRECTION & PRODUCTION CHANGE:* **If the reverse servo piston "cocks" over and misses the pilot hole on the reverse band lever, a "no reverse" condition would result. To prevent the above condition, a new reverse servo piston guide, Part No. 1824474, must be installed. This guide is installed in end of servo piston spring and is held in place by the spring retainer and snap ring. Transmissions having the code letter "F" and later, stamped on the pan rail on right side of case have been changed in production and it is not necessary to install the guide.**

►*1957 TORQUEFLITE ERRATIC SHIFT PATTERN & NO. 3-1 DOWNSHIFT CORRECTION (Reverse push-button cannot be pushed in with engine running):* **This condition may be caused by governor valve or weight sticking due to foreign matter in governor or by governor weight striking output shaft. Check governor pressure with selector lever in "N" position. If pressure is evident (there should be no pressure), inspect governor assembly for cause of sticking. To correct, remove large governor weight and inspect output shaft end for signs of mushrooming. Correct as follows: On all models, except DeSoto Adventurer and Plymouth Fury, grind a 45° chamfer around edge of output shaft end of large governor weight. Diameter of flat surface on end of governor weight must not be less than ¾" after chamfering. On DeSoto Adventurer & Plymouth Fury, the output shaft must be removed and a flat surface ground on shaft surface as indicated in illustration.**

GOVERN R STRIKING CORRECTI N

►*1957 TORQUEFLITE FRONT CLUTCH PRODUCTION CHANGE:* **The early "8 lever" front clutch assembly has been changed to a "4 lever" assembly on later cars. The "8 lever" clutch uses five bonded discs and four steel plates while the "4 lever" clutch uses four bonded discs and three steel plates**

TORQUEFLITE TRANSMISSION (SECTIONAL VIEW)

►*1957 TORQUEFLITE ACCUMULATOR SPRING NOTE:* In some transmissions, two springs, Part Nos. 1732030 and 1732031 were used in the accumulator while other transmissions have one spring, Part No. 1736228. Combined value of the two springs (1732030 & 1732031) are equal to the value of the single spring (1736228) and either may be used.

►*1957 REAR CLUTCH PRESSURE PLATE PRODUCTION CHANGE:* In later transmissions, the rear clutch pressure plate, Part No. 1732114 has been changed to the same plate as used in the front clutch assembly (Part No. 1736408). Later type plate may be used for service replacement in early transmissions. *CAUTION - The later type plate, Part No. 1736408 cannot be used for adjustment of front clutch clearance as previously recommended. See "Front Clutch Pressure Plate Travel Check & Adjustment" below for new procedures.*

►*1957 DESOTO THROTTLE PRESSURE ADJUSTING GAUGE:* This new gauge, Tool C-3610 is to be used only in the event throttle pressure adjustment is suspected of being incorrect (improper part throttle shift pattern, although governor pressure checks satisfactorily and throttle linkage adjustment is known to be correct). *See "Hydraulic Control Pr ssure Ch cks" below.*

►*1957 PLYMOUTH 1-2 UPSHIFT SLIPPAGE OR HARSH SHIFTING CORRECTION:* If this condition occurs, check line pressure *(Se "Hydraulic Control Pressure Tests" below),* and if found to be within specifications, proceed as follows: Attach a tachometer to engine, then with engine operating and transmission in "D" range, raise car on a hoist and attach a pressure gauge in take-off plug on top of kickdown servo. Move accelerator rod until engine reaches 850 RPM (pressure should read 32-34 lbs.). If pressure is not within this range, loosen link on throttle valve rod (adjacent to throttle lever on transmission), and adjust until the correct reading is obtained

►*1957 TORQUEFLITE SPACER WASHER (BETWEEN PLANET PINION CARRIERS) PRODUCTION CHANGE:* A new steel spacer washer, Part No. 1638667 is now being used between the aluminum planet pinion carriers to minimize scuffing.

►*1957 DESOTO S-27 "NO KICKDOWN" CORRECTION:* If this condition exists and throttle linkage cannot be
